Programmable Controller.—Frequently referred to as a PC or PLC (the latter term meaning Programmable Logic Controller), a programmable controller is an electronic unit or small computer. PLCs are used to control machinery, equipment, and complete processes, and to assist CNC systems in the control of complex NC machine tools and flexible manufacturing modules and cells. In effect, PLCs are the technological replacements for electrical relay systems.

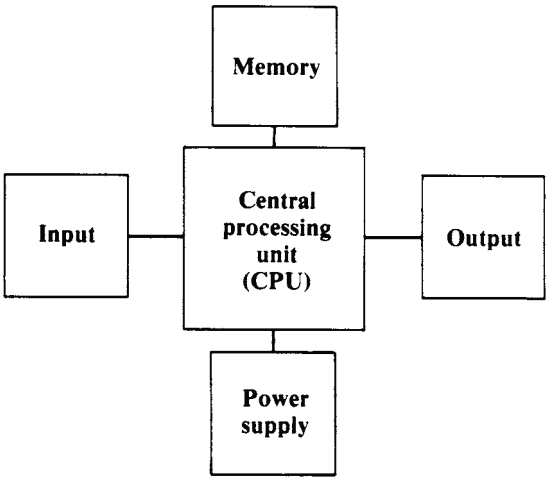

Fig. 1. Programmable Controllers' Four Basic Elements

As shown in Fig. 1, a PLC is composed of four basic elements: the equipment for handling input and output (I/O) signals, the central processing unit (CPU), the power supply, and the memory. Generally, the CPU is a microprocessor and the brain of the PLC. Early PLCs used hardwired special-purpose electronic logic circuits, but most PLCs now being offered are based on microprocessors and have far more logic and control capabilities than was possible with hardwired systems. The CPU scans the status of the input devices continuously, correlates these inputs with the control logic in the memory, and produces the appropriate output responses needed to control the machine or equipment.

Input to a PLC is either discrete or continuous. Discrete inputs may come from push buttons, micro switches, limit switches, photocells, proximity switches or pressure switches, for instance. Continuous inputs may come from sources such as thermocouples, potentiometers, or voltmeters. Outputs from a PLC normally are directed to actuating hardware such as solenoids, solenoid valves, and motor starters. The function of a PLC is to examine the status of an input or set of inputs and, based on this status, actuate or regulate an output or set of outputs.

Digital control logic and sensor input signals are stored in the memory as a series of binary numbers (zeros and ones). Each memory location holds only one “bit” (either 0 or 1) of binary information; however, most of the data in a PLC are used in groups of 8 bits, or bytes. A word is a group of bytes that is operated on at one time by the PLC. The word size in modern PLCs ranges from 8 to 32 bits (1 to 4 bytes), depending on the design of the PLC. In general, the larger the word size that a system is able to operate on (that is, to work on at one time), the faster the system is going to perform. New systems are now beginning to appear that can operate on 64 bits of information at a time.

There are two basic categories of memory: volatile and nonvolatile. Volatile memory loses the stored information when the power is turned off, but nonvolatile memory retains its logic even when power is cut off. A backup battery must be used if the information stored in volatile memory is to be retained. There are six commonly used types of memory. Of these six, random-access memory (RAM) is the most common type because it is the easiest to program and edit. RAM is also the only one of the six common types that is vola-

www.EngineeringEBooksPdf.com

tile memory. The five nonvolatile memory types are: core memory, read-only memory (ROM), programmable read-only memory (PROM), electronically alterable programmable read-only memory (EAPROM), and electronically erasable programmable read-only memory (EEPROM). EEPROMs are becoming more popular due to their relative ease of programming and their nonvolatile characteristic. ROM is often used as a generic term to refer to the general class of read-only memory types and to indicate that this type of memory is not usually reprogrammed.

More than 90 per cent of the microprocessor PLCs now in the field use RAM memory. RAM is primarily used to store data, which are collected or generated by a process, and to store programs that are likely to change frequently. For example, a part program for machining a workpiece on a CNC machining center is loaded into and stored in RAM. When a different part is to be made, a different program can be loaded in its place. The nonvolatile memory types are usually used to store programs and data that are not expected to be changed. Programs that directly control a specific piece of equipment and contain specific instructions that allow other programs (such as a part program stored in RAM) to access and operate the hardware are usually stored in nonvolatile memory or ROM. The benefit of ROM is that stored programs and data do not have to be reloaded into the memory after the power has been turned off.

PLCs are used primarily with handling systems such as conveyors, automatic retrieval and storage systems, robots, and automatic guided vehicles (AGV), such as are used in flexible manufacturing cells, modules, and systems (see *Flexible Manufacturing Systems (FMS)*, *Flexible Manufacturing Cell*, and *Flexible Manufacturing Module*). PLCs are also to be found in applications as diverse as combustion chamber control, chemical process control, and printed-circuit-board manufacturing.

Types of Programmable Controllers

Type	No. of I/Os	General Applications	Math Capability
Mini	32	Replaces relays, timers, and counters.	Yes
Micro	32–64	Replaces relays, timers, and counters.	Yes
Small	64–128	Replaces relays, timers, and counters. Used for materials handling, and some process control.	Yes
Medium	128–512	Replaces relays, timers, and counters. Used for materials handling, process control, and data collection.	Yes
Large	512+	Replaces relays, timers, and counters. Master control for other PLCs and cells and for generation of reports. High-level network capability	Yes

Types of PLCs may be divided into five groups consisting of micro, mini, small, medium, and large according to the number of I/Os, functional capabilities, and memory capacity. The smaller the number of I/Os and memory capacity, and the fewer the functions, the simpler the PLC. Micro and mini PLCs are usually little more than replacements for relay systems, but larger units may have the functional capabilities of a small computer and be able to handle mathematical functions, generate reports, and maintain high-level communications.

www.EngineeringEBooksPdf.com

The preceding guidelines have some gray areas because mini, micro, and small PLCs are now available with large memory sizes and functional capacities normally reserved for medium and large PLCs. The accompanying table compares the various types of PLCs and their applications.

Instructions that are input to a PLC are called programs. Four major programming languages are used with PLCs, comprising ladder diagrams, Boolean mnemonics, functional blocks, and English statements. Some PLC systems even support high-level programming languages such as BASIC and PASCAL. Ladder diagrams and Boolean mnemonics are the basic control-level languages. Functional blocks and English statements are considered high-level languages. Ladder diagrams were used with electrical relay systems before these systems were replaced by PLCs and are still the most popular programming method, so they will be discussed further.

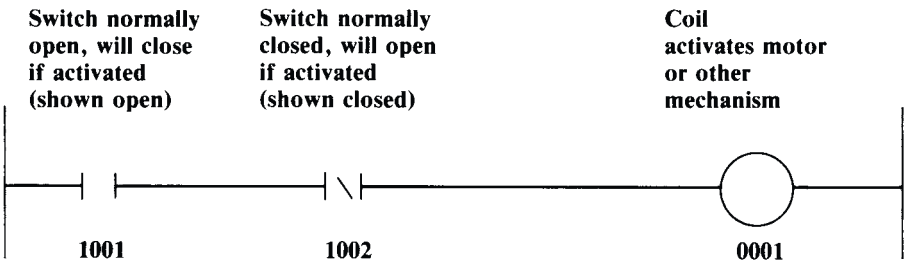

Fig. 2. One Rung on a Ladder Diagram

A ladder diagram consists of symbols, or ladder logic elements, that represent relay contacts or switches and other elements in the control system. One of the more basic symbols represents a normally open switch and is described by the symbol ┤ ├. Another symbol is the normally closed switch, described by the symbol ┤\├. When the normally open switch is activated, it will close, and when the normally closed switch is activated, it will open. Fig. 2 shows one rung (line) on a ladder diagram. Switch 1001 is normally open and switch 1002 is closed. A symbol for a coil (0001) is shown at the right. If switch 1001 is actuated, it will close. If switch 1002 is not activated, it will stay closed. With the two switches closed, current will flow through the line and energize coil 0001. The coil will activate some mechanism such as an electric motor, a robot, or an NC machine tool, for instance.

As an example, Fig. 3 shows a flexible manufacturing module (FMM), consisting of a turning center (NC lathe), an infeed conveyor, an outfeed conveyor, a robot that moves workpieces between the infeed conveyor, the turning center, and the outfeed conveyor, and a PLC. The arrowed lines show the signals going to and coming from the PLC.

Fig. 4 shows a ladder diagram for a PLC that would control the operations of the FMM by:

1) Activating the infeed conveyor to move the workpiece to a position where the robot can pick it up

2) Activating the robot to pick up the workpiece and load it into the chuck on the NC lathe

3) Activating the robot to remove the finished workpiece and place it on the outfeed conveyor

4) Activating the outfeed conveyor to move the workpiece to the next operation

www.EngineeringEBooksPdf.com

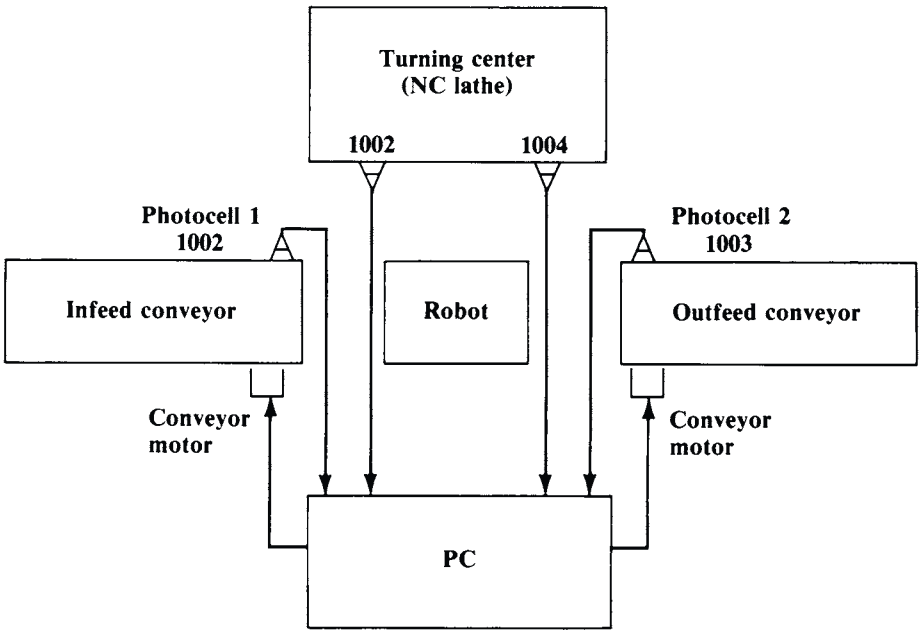

Fig. 3. Layout of a Flexible Manufacturing Module

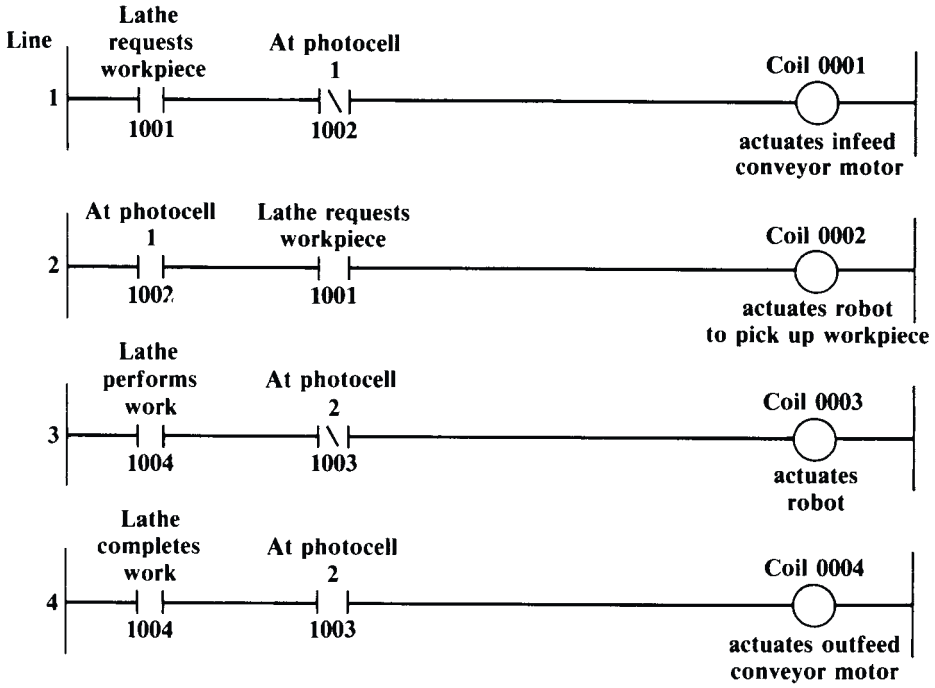

Fig. 4. Portion of a Typical Ladder Diagram for Control of a Flexible Manufacturing Module Including a Turning Center, Conveyors, a Robot, and a Programmable Controller

In Rung 1 of Fig. 4, a request signal for a workpiece from the NC lathe closes the normally open switch 1001. Switch 1002 will remain closed if photocell 1 is not activated, i.e., if it does not detect a workpiece. The signal therefore closes the circuit, energizes the coil, and starts the conveyor motor to bring the next workpiece into position for the robot to grasp.

www.EngineeringEBooksPdf.com

In Rung 2, switch 1002 (which has been changed in the program of the PLC from a normally closed to a normally open switch) closes when it is activated as photocell 1 detects the workpiece. The signal thus produced, together with the closing of the now normally open switch 1001, energizes the coil, causing the robot to pick up the workpiece from the infeed conveyor.

In Rung 3, switch 1004 on the lathe closes when processing of the part is completed and it is ready to be removed by the robot. Photocell 2 checks to see if there is a space on the conveyor to accept the completed part. If no part is seen by photocell 2, switch 1003 will remain closed, and with switch 1004 closed, the coil will be energized, activating the robot to transfer the completed part to the outfeed conveyor.

Rung 4 shows activation of the output conveyor when a part is to be transferred. Normally open switch 1004 was closed when processing of the part was completed. Switch 1003 (which also was changed from a normally closed to a normally open switch by the program) closes if photocell 2 detects a workpiece. The circuit is then closed and the coil is energized, starting the conveyor motor to move the workpiece clear to make way for the succeeding workpiece.

Closed-Loop System.— Also referred to as a servo or feedback system, a closed-loop system is a control system that issues commands to the drive motors of an NC machine. The system then compares the results of these commands as measured by the movement or location of the machine component, such as the table or spindlehead. The feedback devices normally used for measuring movement or location of the component are called resolvers, encoders, Inductosyns, or optical scales. The resolver, which is a rotary analog mechanism, is the least expensive, and has been the most popular since the first NC machines were developed. Resolvers are normally connected to the lead-screws of NC machines. Linear measurement is derived from monitoring the angle of rotation of the leadscrew and is quite accurate.

Encoders also are normally connected to the leadscrew of the NC machine, and measurements are in digital form. Pulses, or a binary code in digital form, are generated by rotation of the encoder, and represent turns or partial turns of the leadscrew. These pulses are well suited to the digital NC system, and encoders have therefore become very popular with such systems. Encoders generally are somewhat more expensive than resolvers.

The Inductosyn (a trade name of Farrand Controls, Inc.) also produces analog signals, but is attached to the slide or fixed part of a machine to measure the position of the table, spindlehead, or other component. The Inductosyn provides almost twice the measurement accuracy of the resolver, but is considerably more expensive, depending on the length of travel to be measured.

Optical scales generally produce information in digital form and, like the Inductosyn, are attached to the slide or fixed part of the machine. Optical scale measurements are more accurate than either resolvers or encoders and, because of their digital nature, are well suited to the digital computer in a CNC system. Like the Inductosyn, optical scales are more costly than either resolvers or encoders.

Open-Loop System.— A control system that issues commands to the drive motors of an NC machine and has no means of assessing the results of these commands is known as an open-loop system. In such a system, no provision is made for feedback of information concerning movement of the slide(s), or rotation of the leadscrew(s). Stepping motors are popular as drives for open-loop systems.

Adaptive Control.— Measuring performance of a process and then adjusting the process to obtain optimum performance is called adaptive control. In the machine tool field, adaptive control is a means of adjusting the feed and/or speed of the cutting tool, based on sensor feedback information, to maintain optimum cutting conditions. A typical arrangement is seen in Fig. 5. Adaptive control is used primarily for cutting higher-strength materials

www.EngineeringEBooksPdf.com

such as titanium, although the concept is applicable to the cutting of any material. The costs of the sensors and software have restricted wider use of the feature.

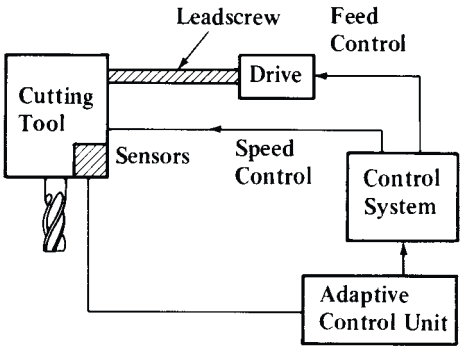

Fig. 5.

The sensors used for adaptive control are generally mounted on the machine drive shafts, tools, or even built into the drive motor. Typically, sensors are used to provide information such as the temperature at the tip of the cutting tool and the cutting force exerted by the tool. The information measured by the sensors is used by the control system computer to analyze the cutting process and adjust the feeds and speeds of the machine to maximize the material removal rate or to optimize another process variable such as surface finish. For the computer to effectively evaluate the process in real time (i.e., while cutting is in progress), details such as maximum allowable tool temperature, maximum allowable cutting force, and information about the drive system need to be integrated into the computer program monitoring the cutting process.

Adaptive control can be used to detect worn, broken, or dull tooling. Ordinarily, the adaptive control system monitors the cutting process to keep the process variables (cutting speed and feed rate, for example) within the proper range. Because the force required to machine a workpiece is lowest when the tool is new or recently resharpened, a steady increase in cutting force during a machining operation, assuming that the feed remains the same, is an indication that the tool is becoming dull (temperature may increase as well). Upon detecting cutting forces that are greater than a predetermined maximum allowable force, the control system causes the feed rate, the cutting speed, or both to be adjusted to maintain the cutting force within allowable limits. If the cutting force cannot be maintained without causing the speed and/or feed rate to be adjusted outside its allowable limits, the machine will be stopped, indicating that the tool is too dull and must be resharpened or replaced.

On some systems, the process monitoring equipment can interface directly with the machine control system, as discussed above. On other systems, the adaptive control is implemented by a separate monitoring system that is independent of the machine control system. These systems include instrumentation to monitor the operations of the machine tool, but do not have the capability to directly change operating parameters, such as feeds and speeds. In addition, this type of control does not require any modification of the existing part programs for control of the machine.

Flexible Manufacturing Systems (FMS).— A flexible manufacturing system (FMS) is a computer-controlled machining arrangement that can perform a variety of continuous metal-cutting operations on a range of components without manual intervention. The objective of such a system is to produce components at the lowest possible cost, especially components of which only small quantities are required. Flexibility, or the ability to switch from manufacture of one type of component to another, or from one type of machining to another, without interrupting production, is the prime requirement of such a system. In general, FMS are used for production of numbers of similar parts between 200 and 2000,

www.EngineeringEBooksPdf.com

although larger quantities are not uncommon. An FMS involves almost all the departments in a company, including engineering, methods, tooling and part programming, planning and scheduling, purchasing, sales and customer service, accounting, maintenance, and quality control. Initial costs of an FMS are estimated as being borne (percentages in parentheses) by machine tools (46.2), materials handling systems (7.7), tooling and fixtures (5.9), pallets (1.9), computer hardware (3.7), computer software (2.2), wash stations (2.8), automatic storage and retrieval systems (6.8), coolant and chip systems (2.4), spares (2), and others (18.4).

FMS are claimed to bring reductions in direct labor (80–90), production planning and control (65), and inspection (70). Materials handling and shop supervision are reduced, and individual productivity is raised. In the materials field, savings are made in tooling (35), scrap and rework (65), and floor space (50). Inventory is reduced and many other costs are avoided. Intangible savings claimed to result from FMS include reduced tooling changeover time, ability to produce complex parts, to incorporate engineering changes more quickly and efficiently than with other approaches, and to make special designs, so that a company can adapt quickly to changing market conditions. Requirements for spare parts with good fit are easily met, and the lower costs combine with higher quality to improve market share. FMS also are claimed to improve morale among workers, leading to higher productivity, with less paper work and more orderly shop operations. Better control of costs and improved cost data help to produce more accurate forecasts of sales and manpower requirements. Response to surges in demand and more economical materials ordering are other advantages claimed with FMS.

Completion of an FMS project is said to average 57 months, including 20 months from the time of starting investigations to the placing of the purchase order. A further 13 months are needed for delivery and a similar period for installation. Debugging and building of production takes about another 11 months before production is running smoothly. FMS are expensive, requiring large capital outlays and investments in management time, software, engineering, and shop support. Efficient operation of FMS also require constant workflow because gaps in the production cycle are very costly.

Flexible Manufacturing Cell.— A flexible manufacturing cell usually consists of two or three NC machines with some form of pallet-changing equipment or an industrial robot. Prismatic-type parts, such as would be processed on a machining center, are usually handled on pallets. Cylindrical parts, such as would be machined on an NC lathe, usually are handled with an overhead type of robot. The cell may be controlled by a computer, but is often run by programmable controllers. The systems can be operated without attendants, but the mixture of parts usually must be less than with a flexible manufacturing system (FMS).

Flexible Manufacturing Module.— A flexible manufacturing module is defined as a single machining center (or turning center) with some type of automatic materials handling equipment such as multiple pallets for machining centers, or robots for manipulating cylindrical parts and chucks for turning centers. The entire module is usually controlled by one or more programmable logic controllers.

Numerical Control Programming

Programming.— A numerical control (NC) program is a list of instructions (commands) that completely describes, in sequence, every operation to be carried out by a machine. When a program is run, each instruction is interpreted by the machine controller, which causes an action such as starting or stopping of a spindle or coolant, changing of spindle speed or rotation, or moving a table or slide a specified direction, distance, or speed. The form that program instructions can take, and how programs are stored and/or loaded into the machine, depends on the individual machine/control system. However, program instructions must be in a form (language) that the machine controller can understand.

www.EngineeringEBooksPdf.com

A programming language is a system of symbols, codes, and rules that describes the manner in which program instructions can be written. One of the earliest and most widely recognized numerical control programming languages is based on the Standard ANSI/EIA RS-274-D-1980. The standard defines a recommended data format and codes for sending instructions to machine controllers. Although adherence to the standard is not mandatory, most controller manufacturers support it and most NC machine controllers (especially controllers on older NC machines using tape input) can accept data in a format that conforms, at least in part, with the recommended codes described in the RS-274-D standard. Most newer controllers also accept instructions written in proprietary formats offered (specified) by the controller's manufacturer.

One of the primary benefits of a standardized programming format is easy transfer of programs from one machine to another, but even standardized code formats such as RS-274-D are implemented differently on different machines. Consequently, a program written for one machine may not operate correctly on another machine without some modification of the program. On the other hand, proprietary formats are attractive because of features that are not available using the standardized code formats. For example, a proprietary format may make available certain codes that allow a programmer, with only a few lines of code, to program complex motions that would be difficult or even impossible to do in the standard language. The disadvantage of proprietary formats is that transferring programs to another machine may require a great deal of program modification or even complete rewriting. Generally, with programs written in a standardized format, the modifications required to get a program written for one machine to work on another machine are not extensive.

In programming, before describing the movement of any machine part, it is necessary to establish a coordinate system(s) as a reference frame for identifying the type and direction of the motion. A description of accepted terminology used worldwide to indicate the types of motion and the orientation of machine axes is contained in a separate section (Axis Nomenclature). Part geometry is programmed with reference to the same axes as are used to describe motion.

Manual data input (MDI) permits the machine operator to insert machining instructions directly into the NC machine control system via push buttons, pressure pads, knobs, or other arrangements. MDI has been available since the earliest NC machines were designed, but the method was less efficient than tape for machining operations and was used primarily for setting up the NC machine. Computer numerical control (CNC) systems, with their canned cycles and other computing capabilities, have now made the MDI concept more feasible and for some work MDI may be more practical than preparing a program. The choice depends very much on the complexity of the machining work to be done and, to a lesser degree, on the skill of the person who prepares the program.

Conversational part programming is a form of MDI that requires the operator or programmer to answer a series of questions displayed on the control panel of the CNC. The operator replies to questions that describe the part, material, tool and machine settings, and machining operations by entering numbers that identify the material, blank size and thickness or diameter, tool definitions, and other required data. Depending on capability, some controls can select the required spindle speed and feed rate automatically by using a materials look-up table; other systems request the appropriate feed and speed data. Tool motions needed to machine a part are described by selecting a linear or circular motion programming mode and entering endpoint and intersection coordinates of lines and radius, diameter, tangent points, and directions of arcs and circles (with some controllers, intersection and tangent points are calculated automatically). Machined elements such as holes, slots, and bolt circles are entered by selecting the appropriate tool and describing its action, or with “canned routines” built into the CNC to perform specific machining operations. On some systems, if a feature is once described, it can be copied and/or moved by: translation (copy and/or move), rotation about a point, mirror image (copy and rotate about an axis),

www.EngineeringEBooksPdf.com

and scaling (copy and change size). On many systems, as each command is entered, a graphic image of the part or operation gives a visual check that the program is producing the intended results. When all the necessary data have been entered, the program is constructed and can be run immediately or saved on tape, floppy disk, or other storage media for later use.

Conversational programming gives complete control of machine operations to the shop personnel, taking advantage of the experience and practical skills of the machine operator/programmer. Control systems that provide conversational programming usually include many built-in routines (fixed or canned cycles) for commonly used machining operations and may also have routines for specialized operations. Built-in routines speed programming because one command may replace many lines of program code that would take considerable time to write. Some built-in cycles allow complex machining operations to be programmed simply by specifying the final component profile and the starting stock size, handling such details as developing tool paths, depth of cut, number of roughing passes, and cutter speed automatically. On turning machines, built-in cycles for reducing diameters, chamfer and radius turning, and cutting threads automatically are common. Although many CNC machines have a conversational programming mode, the programming methods used and the features available are not standardized. Some control systems cannot be programmed from the control panel while another program is running (i.e., while a part is being machined), but those systems that can be thus programmed are more productive because programming does not require the machine to be idle. Conversational programming is especially beneficial In reducing programming time in shops that do most of their part programming from the control panel of the machine.

Manual part programming describes the preparation of a part program by manually writing the part program in word addressed format. In the past, this method implied programming without using a computer to determine tool paths, speeds and feeds, or any of the calculations normally required to describe the geometry of a part. Today, however, computers are frequently used for writing and storing the program on disk, as well as for calculations required to program the part. Manual part programming consists of writing codes, in a format appropriate to the machine controller, that instruct the controller to perform a specific action. The most widely accepted form of coding the instructions for numerically controlled machines uses the codes and formats suggested in the ANSI/EIA RS-274-D-1980, standard. This type of programming is sometimes called G-code programming, referring to a commonly used word address used in the RS-274-D standard. Basic details of programming in this format, using the various codes available, are discussed in the next section (G-Code Programming).

Computer-assisted part programming (CAPP) uses a computer to help in the preparation of the detailed instructions for operating an NC machine. In the past, defining a curve or complicated surface profile required a series of complex calculationsto describe the features in intimate detail. However, with the introduction of the microprocessor as an integral part of the CNC machine, the process of defining many complex shapes has been reduced to the simple task of calling up a canned cycle to calculate the path of the cutter. Most new CNC systems have some graphic programming capability, and many use graphic images of the part "drawn" on a computer screen. The part programmer moves a cutter about the part to generate the part program or the detailed block format instructions required by the control system. Machining instructions, such as the speed and feed rate, are entered via the keyboard. Using the computer as an assistant is faster and far more accurate than the manual part programming method.

Computer-assisted part programming methods generally can be characterized as either language-based or graphics-based, the distinction between the two methods being primarily in the manner by which the tool paths are developed. Some modern-language-based programming systems, such as Compact II, use interactive alphanumeric input so that programming errors are detected as soon as they are entered. Many of these programming sys-

www.EngineeringEBooksPdf.com

tems are completely integrated with computer graphics and display an image of the part or operation as soon as an instruction is entered. The language-based programming systems are usually based on, or are a variation of, the APT programming language, which is discussed separately within this section (APT Programming).

The choice between computer-assisted part programming and manual part programming depends on the complexity of the part (particularly its geometry) and how many parts need to be programmed. The more complicated the part, the more benefit to be gained by CAPP, and if many parts are to be programmed, even if they are simple ones, the benefits of a computer-aided system are substantial. If the parts are not difficult to program but involve much repetition, computer-assisted part programming may also be preferred. If parts are to be programmed for several different control systems, a high-level part programming language such as APT will make writing the part programs easier. Because almost all machines have some deviations from standard practices, and few control systems use exactly the same programming format, a higher-level language allows the programmer to concentrate primarily on part geometry and machining considerations. The postprocessors (see *Postprocessors* below) for the individual control systems accommodate most of the variations in the programming required. The programmer only needs to write the program; the postprocessor deals with the machine specifics.

Graphical programming involves building a two- or three-dimensional model of a part on a computer screen by graphically defining the geometric shapes and surfaces of the part using the facilities of a CAD program. In many cases, depending on features of the CAD software package, the same computer drawing used in the design and drafting stage of a project can also be used to generate the program to produce the part. The graphical entities, such as holes, slots, and surfaces, are linked with additional information required for the specific machining operations needed. Most of the cutter movements (path of the cutter), such as those needed for the generation of pockets and lathe roughing cuts, are handled automatically by the computer. The program may then sort the various machining operations into an efficient sequence so that all operations that can be performed with a particular tool are done together, if possible. The output of graphical part programming is generally an alphanumeric part programming language output file, in a format such as an APT or Compact II file.

The part programming language file can be manually checked, and modified, as necessary before being run, and to help detect errors, many graphics programming systems also include some form of part verification software that simulates machining the part on the computer screen. Nongraphic data, such as feed rates, spindle speeds and coolant on/off, must be typed in by the part programmer or entered from acomputer data base at the appropriate points in the program, although some programs prompt for this information when needed. When the part program language file is run or compiled, the result is a center line data (CL data) file describing the part. With most computer-aided part programming output files, the CL data file needs to be processed through a postprocessor (see *Postprocessors* below) to tailor the final code produced to the actual machine being used. Postprocessor output is in a form that can be sent directly to the control system, or can be saved on tape or magnetic media and transferred to the machine tool when necessary. The graphic image of the part and the alphanumeric output files are saved in separate files so that either can be edited in the future if changes in the part become necessary. Revised files must be run and processed again for the part modifications to be included in the part program. Software for producing part programs is discussed further in the CAD/CAM section.

Postprocessors.—A postprocessor is computer software that contains a set of computer instructions designed to tailor the cutter center line location data (CL data), developed by a computerized part programming language, to meet the requirements of a particular machine tool/system combination. Generally, when a machine tool is programmed in a graphical programming environment or any high-level language such as APT, a file is cre-

www.EngineeringEBooksPdf.com

ated that describes all movements required of a cutting tool to make the part. The file thus created is run, or compiled, and the result is a list of coordinates (CL data) that describes the successive positions of the cutter relative to the origin of the machine's coordinate system. The output of the program must be customized to fit the input requirements of the machine controller that will receive the instructions. Cutter location data must be converted into a format recognized by the control system, such as G codes and M codes, or into another language or proprietary format recognized by the controller. Generally, some instructions are also added or changed by the programmer at this point.

The lack of standardization among machine tool control systems means that almost all computerized part programming languages require a postprocessor to translate the computer-generated language instructions into a form that the machine controller recognizes. Postprocessors are software and are generally prepared for a fee by the machine tool builder, the control system builder, a third party vendor, or by the user.

G-Code Programming

Programs written to operate numerical control (NC) machines with control systems that comply with the ANSI/EIA RS-274-D-1980, Standard consist of a series of data blocks, each of which is treated as a unit by the controller and contains enough information for a complete command to be carried out by the machine. Each block is made up of one or more words that indicate to the control system how its corresponding action is to be performed. A word is an ordered set of characters, consisting of a letter plus some numerical digits, that triggers a specific action of a machine tool. The first letter of the word is called the letter address of the word, and is used to identify the word to the control system. For example, X is the letter address of a dimension word that requires a move in the direction of the X-axis, Y is the letter address of another dimension word; and F is the letter address of the feed rate. The assigned letter addresses and their meanings, as listed in ANSI/EIA RS-274-D, are shown in Table 1.

Format Classification.— The *format classification sheet* completely describes the format requirements of a control system and gives other important information required to program a particular control including: the type of machine, the format classification shorthand and format detail, a listing of specific letter address codes recognized by the system (for example, G-codes: G01, G02, G17, etc.) and the range of values the available codes may take (S range: 10 to 1800 rpm, for example), an explanation of any codes not specifically assigned by the Standard, and any other unique features of the system.

The format classification shorthand is a nine- or ten-digit code that gives the type of system, the number of motion and other words available, the type and format of dimensional data required by the system, the number of motion control channels, and the number of numerically controlled axes of the system. The *format detail* verysuccinctly summarizes details of the machine and control system. This NC shorthand gives the letter address words and word lengths that can be used to make up a block. The format detail defines the basic features of the control system and the type of machine tool to which it refers. For example, the format detail

N4G2X + 24Y + 24Z + 24B24I24J24F31T4M2

specifies that the NC machine is a machining center (has *X*-, *Y*-, and *Z*-axes) and a tool changer with a four-digit tool selection code (T4); the three linear axes are programmed with two digits before the decimal point and four after the decimal point (X + 24Y + 24Z + 24) and can be positive or negative; probably has a horizontal spindle and rotary table (B24 = rotary motion about the *Y*-axis); has circular interpolation (I24J24); has a feed rate range in which there are three digits before and one after the decimal point (F31); and can handle a four-digit sequence number (N4), two-digit G-words (G2), and two-digit miscellaneous words (M2). The sequence of letter addresses in the format detail is also the sequence in which words with those addresses should appear when used in a block.

www.EngineeringEBooksPdf.com

Table 1. Letter Addresses Used in Numerical Control

Letter Address	Description	Refers to
A	Angular dimension about the *X*-axis. Measured in decimal parts of a degree	Axis nomenclature
B	Angular dimension about the *Y*-axis. Measured in decimal parts of a degree	Axis nomenclature
C	Angular dimension about the *Z*-axis. Measured in decimal parts of a degree	Axis nomenclature
D	Angular dimension about a special axis, or third feed function, or tool function for selection of tool compensation	Axis nomenclature
E	Angular dimension about a special axis or second feed function	Axis nomenclature
F	Feed word (code)	Feed words
G	Preparatory word (code)	Preparatory words
H	Unassigned	
I	Interpolation parameter or thread lead parallel to the *X*-axis	Circular interpolation and threading
J	Interpolation parameter or thread lead parallel to the *Y*-axis	Circular interpolation and threading
K	Interpolation parameter or thread lead parallel to the *Z*-axis	Circular interpolation and threading
L	Unassigned	
M	Miscellaneous or auxilliary function	Miscellaneous functions
N	Sequence number	Sequence number
O	Sequence number for secondary head only	Sequence number
P	Third rapid-traverse dimension or tertiary-motion dimension parallel to *X*	Axis nomenclature
Q	Second rapid-traverse dimension or tertiary-motion dimension parallel to *Y*	Axis nomenclature
R	First rapid-traverse dimension or tertiary-motion dimension parallel to *Z* or radius for constant surface-speed calculation	Axis nomenclature
S	Spindle-speed function	Spindle speed
T	Tool function	Tool function
U	Secondary-motion dimension parallel to *X*	Axis nomenclature
V	Secondary-motion dimension parallel to *Y*	Axis nomenclature
W	Secondary-motion dimension parallel to *Z*	Axis nomenclature
X	Primary *X*-motion dimension	Axis nomenclature
Y	Primary *Y*-motion dimension	Axis nomenclature
Z	Primary *Z*-motion dimension	Axis nomenclature

www.EngineeringEBooksPdf.com

The information given in the format shorthand and format detail is especially useful when programs written for one machine are to be used on different machines. Programs that use the variable block data format described in RS-274-D can be used interchangeably on systems that have the same format classification, but for complete program compatibility between machines, other features of the machine and control system must also be compatible, such as the relationships of the axes and the availability of features and control functions.

Control systems differ in the way that the numbers may be written. Most newer CNC machines accept numbers written in a decimal-point format, however, some systems require numbers to be in a fixed-length format that does not use an explicit decimal point. In the latter case, the control system evaluates a number based on the number of digits it has, including zeros. *Zero suppression* in a control system is an arrangement that allows zeros before the first significant figure to be dropped (leading zero suppression) or allows zeros after the last significant figure to be dropped (trailing zero suppression). An *X*-axis movement of 05.3400, for example, could be expressed as 053400 if represented in the full field format, 53400 (leading zero suppression), or 0534 (trailing zero suppression). With decimal-point programming, the above number is expressed simply as 5.34. To ensure program compatibility between machines, all leading and trailing zeros should be included in numbers unless decimal-point programming is used.

Sequence Number (N-Word).—A block normally starts with a sequence number that identifies the block within the part program. Most control systems use a four-digit sequence number allowing step numbers up to N9999. The numbers are usually advanced by fives or tens in order to leave spaces for additional blocks to be inserted later if required. For example, the first block in a program would be N0000, the next block N0005; the next N0010; and so on. The slash character, /, placed in a block, before the sequence number, is called an *optional stop* and causes the block to be skipped over when actuated by the operator. The block that is being worked on by the machine is often displayed on a digital readout so that the operator may know the precise operation being performed.

Preparatory Word (G-Word).—A preparatory word (also referred to as a preparatory function or G-code) consists of the letter address G and usually two digits. The preparatory word is placed at the beginning of a block, normally following the sequence number. Most newer CNC machines allow more than one G-code to be used in a single block, although many of the older systems do not. To ensure compatability with older machines and with the RS-274-D Standard, only one G-code per block should be used.

The G-word indicates to the control system how to interpret the remainder of theblock. For example, G01 refers to linear interpolation and indicates that the words following in the block will move the cutter in a straight line. The G02 code indicates that the words following in the block will move the cutter in a clockwise circular path. A G-word can completely change the normal meaning of other words in a block. For example, X is normally a dimension word that describes a distance or position in the *X*-direction. However, if a block contains the G04 word, which is the code for a dwell, the X word represents the time, in seconds, that the machine is to dwell.

The majority of G-codes are designated as modal, which means that once used, the code remains in effect for succeeding blocks unless it is specifically changed or canceled. Therefore, it is not necessary to include modal G-codes in succeeding blocks except to change or cancel them. Unless a G-code is modal, it is only effective within its designated block for the operation it defines. Table 2, G-Code Addresses, lists standardized G-code addresses and modality.

www.EngineeringEBooksPdf.com

Table 2. G-Code Addresses

Code		Description	Code		Description
G00	ab*	Rapid traverse, point to point (M,L)	G34	ab*	Thread cutting, increasing lead (L)
G01	abc	Linear interpolation (M,L)	G35	abc	Thread cutting, decreasing lead (L)
G02	abc	Circular interpolation — clockwise movement (M,L)	G36-G39	ab	Permanently unassigned
			G36	c	Used for automatic acceleration and deceleration when the blocks are short (M,L)
G03	abc	Circular interpolation—counter-clockwise movement (M,L)			
G04	ab	Dwell—a programmed time delay (M,L)	G37, G37.1, G37.2, G37.3		Used for tool gaging (M,L)
G05	ab	Unassigned	G37.4		
G06	abc	Parabolic interpolation (M,L)	G38		Used for probing to measure the diameter and center of a hole (M)
G07	c	Used for programming with cylindrical diameter values (L)	G38.1		Used with a probe to measure the parallelness of a part with respect to an axis (M)
G08	ab	Programmed acceleration (M,L). [d] Also for lathe programming with cylindrical diameter values	G39, G39.1		Generates a nonprogrammed block to improve cycle time and corner cutting quality when used with cutter compensation (M)
G09	ab	Programmed deceleration (M,L). [d] Used to stop the axis movement at a precise location (M,L)	G39		Tool tip radius compensation used with linear generated block (L)
G10-G12	ab	Unassigned. [d]Sometimes used for machine lock and unlock devices	G39.1		Tool tip radius compensation used used with circular generated block (L)
G13-G16	ac	Axis selection (M,L)	G40	abc	Cancel cutter compensation/ offset (M)
G13-G16	b	Unassigned	G41	abc	Cutter compensation, left (M)
G13		Used for computing lines and circle intersections (M,L)	G42	abc	Cutter compensation, right (M)
G14, G14.1	c	Used for scaling (M,L)	G43	abc	Cutter offset, inside corner (M,L)
G15-G16	c	Polar coordinate programming (M)	G44	abc	Cutter offset, outside corner (M,L)
G15, G16.1	c	Cylindrical interpolation—C axis (L)	G45-G49	ab	Unassigned
G16.2	c	End face milling—C axis (L)	G50-G59	a	Reserved for adaptive control (M,L)
G17-G19	abc	*X-Y*, *X-Z*, *Y-Z* plane selection, respectively (M,L)	G50	bb	Unassigned
G20		Unassigned	G50.1	c	Cancel mirror image (M,L)
G22-G32	ab	Unassigned	G51.1	c	Program mirror image (M,L)
G22-G23	c	Defines safety zones in which the machine axis may not enter (M,L)	G52	b	Unassigned
G22.1, G233.1	c	Defines safety zones in which the cutting tool may not exit (M,L)	G52		Used to offset the axes with respect to the coordinate zero point (see G92) (M,L)
G24	c	Single-pass rough-facing cycle (L)	G53	bc	Datum shift cancel
G27-G29		Used for automatically moving to and returning from home position (M,L)	G53	c	Call for motion in the machine coordinate system (M,L)
			G54-G59	bc	Datum shifts (M,L)
G30		Return to an alternate home position (M,L)	G54-G59.3	c	Allows for presetting of work coordinate systems (M,L)
G31, G31.1, G31.2, G31.3, G31.4		External skip function, moves an axis on a linear path until an external signal aborts the move (M,L)	G60-G62	abc	Unassigned
G33	abc	Thread cutting, constant lead (L)

Table 2. *(Continued)* **G-Code Addresses**

Code		Description	Code		Description
G61	c	Modal equivalent of G09 except that rapid moves are not taken to a complete stop before the next motion block is executed (M,L)	G80	abc	Cancel fixed cycles
			G81	abc	Drill cycle, no dwell and rapid out (M,L)
G62	c	Automatic corner override, reduces the feed rate on an inside corner cut (M,L)	G82	abc	Drill cycle, dwell and rapid out (M,L)
G63	a	Unassigned	G83	abc	Deep hole peck drilling cycle (M,L)
G63	bc	Tapping mode (M,L)	G84	abc	Right-hand tapping cycle (M,L)
G64-G69	abc	Unassigned	G84.1	c	Left-hand tapping cycle (M,L)
G64	c	Cutting mode, usually set by the system installer (M,L)	G85	abc	Boring cycle, no dwell, feed out (M,L)
G65	c	Calls for a parametric macro (M,L)	G86	abc	Boring cycle, spindle stop, rapid out (M,L)
G66	c	Calls for a parametric macro. Applies to motion blocks only (M,L)	G87	abc	Boring cycle, manual retraction (M,L)
			G88	abc	Boring cycle, spindle stop, manual retraction (M,L)
G66.1	c	Same as G66 but applies to all blocks (M,L)	G88.1		Pocket milling (rectangular and circular), roughing cycle (M)
G67	c	Stop the modal parametric macro (see G65, G66, G66.1) (M,L)	G88.2		Pocket milling (rectangular and circular), finish cycle (M)
G68	c	Rotates the coordinate system (i.e., the axes) (M)	G88.3		Post milling, roughs out material around a specified area (M)
G69	c	Cancel axes rotation (M)	G88.4		Post milling, finish cuts material around a post (M)
G70	abc	Inch programming (M,L)	G88.5		Hemisphere milling, roughing cycle (M)
G71	abc	Metric programming (M,L)			
G72	ac	Circular interpolation CW (three-dimensional) (M)	G88.6		Hemisphere milling, finishing cycle (M)
G72	b	Unassigned			
G72	c	Used to perform the finish cut on a turned part along the Z-axis after the roughing cuts initiated under G73, G74, or G75 codes (L)	G89	abc	Boring cycle, dwell and feed out (M,L)
			G89.1		Irregular pocket milling, roughing cycle (M)
G73	b	Unassigned			
G73	c	Deep hole peck drilling cycle (M); OD and ID roughing cycle, running parallel to the Z-axis (L)	G89.2		Irregular pocket milling, finishing cycle (M)
G74	ac	Cancel multiquadrant circular interpolation (M,L)	G90	abc	Absolute dimension input (M,L)
G74	bc	Move to home position (M,L)	G91	abc	Incremental dimension input (M,L)
G74	c	Left-hand tapping cycle (M)	G92	abc	Preload registers, used to shift the coordinate axes relative to the current tool position (M,L)
G74		Rough facing cycle (L)	G93	abc	Inverse time feed rate (velocity/distance) (M,L)
G75	ac	Multiquadrant circular interpolation (M,L)	G94	c	Feed rate in inches or millimeters per minute (ipm or mpm) (M,L)
G75	b	Unassigned	G95	abc	Feed rate given directly in inches or millimeters per revolution (ipr or mpr) (M,L)
G75		Roughing routine for castings or forgings (L)			
G76-G79	ab	Unassigned	G96	abc	Maintains a constant surface speed, feet (meters) per minute (L)
			G97	abc	Spindle speed programmed in rpm (M,L)
			G98-99	ab	Unassigned

www.EngineeringEBooksPdf.com

[a] Adheres to ANSI/EIA RS-274-D;

[b] Adheres to ISO 6983/1,2,3 Standards; where both symbols appear together, the ANSI/EIA and ISO standard codes are comparable;

[c] This code is modal. All codes that are not identified as modal are nonmodal, when used according to the corresponding definition.

[d] Indicates a use of the code that does not conform with the Standard.

Symbols following a description: (M) indicates that the code applies to a mill or machining center; (L) indicates that the code applies to turning machines; (M,L) indicates that the code applies to both milling and turning machines.

Codes that appear more than once in the table are codes that are in common use, but are not defined by the Standard or are used in a manner that is different than that designated by the Standard (e.g., see G61).

Most systems that support the RS-274-D Standard codes do not use all the codes available in the Standard. Unassigned G-words in the Standard are often used by builders of machine tool control systems for a variety of special purposes, sometimes leading to confusion as to the meanings of unassigned codes. Even more confusing, some builders of systems and machine tools use the less popular standardized codes for other than the meaning listed in the Standard. For these reasons, machine code written specifically for one machine/controller will not necessarily work correctly on another machine controller without modification.

Dimension words contain numerical data that indicate either a distance or a position. The dimension units are selected by using G70 (inch programming) or G71 (metric programming) code. G71 is canceled by a G70 command, by miscellaneous functions M02 (end of program), or by M30 (end of data). The dimension words immediately follow the G-word in a block and on multiaxis machines should be placed in the following order: X, Y, Z, U, V, W, P, Q, R, A, B, C, D, and E.

Absolute programming (G90) is a method of defining the coordinate locations of points to which the cutter (or workpiece) is to move based on the fixed machine zero point. In Fig. 1, the $X - Y$ coordinates of P1 are $X = 1.0$, $Y = 0.5$ and the coordinates of P2 are $X = 2.0$, $Y = 1.1$. To indicate the movement of the cutter from one point to another when using the absolute coordinate system, only the coordinates of the destination point P2 are needed.

Incremental programming (G91) is a method of identifying the coordinates of a particular location in terms of the distance of the new location from the current location. In the example shown in Fig. 2, a move from P1 to P2 is written as X + 1.0, Y + 0.6. If there is no movement along the *Z*-axis, *Z* is zero and normally is not noted. An $X - Y$ incremental move from P2 to P3 in Fig. 2 is written as X + 1.0, Y – 0.7.

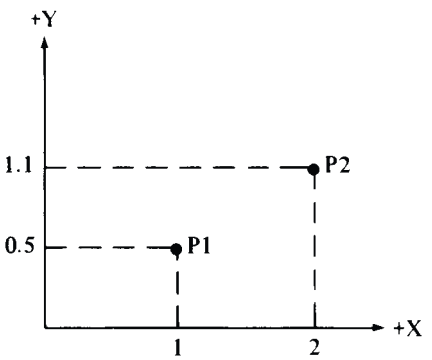

Fig. 1.

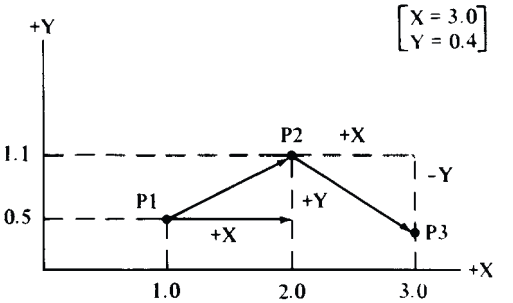

Fig. 2.

Most CNC systems offer both absolute and incremental part programming. The choice is handled by G-code G90 for absolute programming and G91 for incremental programming. G90 and G91 are both modal, so they remain in effect until canceled.

www.EngineeringEBooksPdf.com

The G92 word is used to preload the registers in the control system with desired values. A common example is the loading of the axis-position registers in the control system for a lathe. Fig. 3 shows a typical home position of the tool tip with respect to the zero point on the machine. The tool tip here is registered as being 15.0000 inches in the *Z*-direction and 4.5000 inches in the *X*-direction from machine zero. No movement of the tool is required. Although it will vary with different control system manufacturers, the block to accomplish the registration shown in Fig. 3 will be approximately:

N0050 G92 X4.5 Z15.0

Miscellaneous Functions (M-Words).—Miscellaneous functions, or M-codes, also referred to as auxiliary functions, constitute on-off type commands. M functions are used to control actions such as starting and stopping of motors, turning coolant on and off, changing tools, and clamping and unclamping parts. M functions are made up of the letter M followed by a two-digit code. Table 3 lists the standardized M-codes, however, the functions available will vary from one control system to another. Most systems provide fewer M functions than the complete list and may use some of the unassigned codes to provide additional functions that are not covered by the Standard. If an M-code is used in a block, it follows the T-word and is normally the last word in the block.

Table 3. Miscellaneous Function Words from *ANSI/EIA RS-274-D*

Code	Description
M00	Automatically *stops* the machine. The operator must push a button to continue with the remainder of the program.
M01	An *optional stop* acted upon only when the operator has previously signaled for this command by pushing a button. The machine will automatically stop when the control system senses the M01 code.
M02	This *end-of-program* code stops the machine when all commands in the block are completed. May include rewinding of tape.
M03	Start *spindle rotation* in a *clockwise* direction—looking out from the spindle face.
M04	Start *spindle rotation* in a *counterclockwise* direction—looking out from the spindle face.
M05	*Stop* the spindle in a normal and efficient manner.
M06	Command to *change a tool* (or tools) manually or automatically. Does not cover tool selection, as is possible with the T-words.
M07 to M08	M07 (coolant 2) and M08 (coolant 1) are codes to *turn on coolant.* M07 may control *flood* coolant and M08 *mist* coolant.
M09	Shuts off the coolant.
M10 to M11	M10 applies to automatic *clamping* of the machine slides, workpiece, fixture spindle, etc. M11 is an unclamping code.
M12	An inhibiting code used to synchronize multiple sets of axes, such as a four-axis lathe having two independently operated heads (turrets).
M13	Starts *CW spindle* motion and *coolant on* in the same command.
M14	Starts *CCW spindle* motion and *coolant on* in the same command.
M15 to M16	Rapid traverse of feed motion in either the +(M15) or –(M16) direction.
M17 to M18	Unassigned.
M19	Oriented spindle stop. Causes the spindle to stop at a predetermined angular position.
M20 to M29	Permanently unassigned.
M30	An *end-of-tape* code similar to M02, but M30 will also rewind the tape; also may switch automatically to a second tape reader.
M31	A command known as *interlock bypass* for temporarily circumventing a normally provided interlock.

www.EngineeringEBooksPdf.com

Table 3. *(Continued)* **Miscellaneous Function Words from** *ANSI/EIA RS-274-D*

Code	Description
M32 to M35	Unassigned.
M36 to M39	Permanently unassigned.
M40 to M46	Used to signal gear changes if required at the machine; otherwise, unassigned.
M47	Continues program execution from the start of the program unless inhibited by an interlock signal.
M48 to M49	M49 deactivates a manual spindle or feed override and returns the parameter to the programmed value; M48 cancels M49.
M50 to M57	Unassigned.
M58 to M59	Holds the rpm constant at the value in use when M59 is initiated; M58 cancels M59.
M60 to M89	Unassigned.
M90 to M99	Reserved for use by the machine user.

Feed Function (F-Word).—F-word stands for feed-rate word or feed rate. The meaning of the feed word depends on the system of units in use and the feed mode. For example, F15 could indicate a feed rate of 0.15 inch (or millimeter) per revolution or 15 inches (or millimeters) per minute, depending on whether G70 or G71 is used to indicate inch or metric programming and whether G94 or G95 is used to specify feed rate expressed as inches (or mm) per minute or revolution. The G94 word is used to indicate inches/minute (ipm) or millimeters/minute (mmpm) and G95 is used for inches/revolution (ipr) or millimeters/revolution (mmpr). The default system of units is selected by G70 (inch programming) or G71 (metric programming) prior to using the feed function. The feed function is modal, so it stays in effect until it is changed by setting a new feed rate. In a block, the feed function is placed immediately following the dimension word of the axis to which it applies or immediately following the last dimension word to which it applies if it is used for more than one axis.

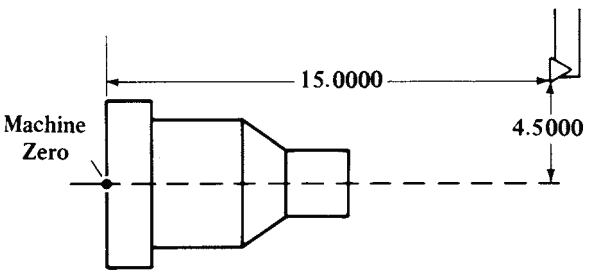

Fig. 3.

In turning operations, when G95 is used to set a constant feed rate per revolution, the spindle speed is varied to compensate for the changing diameter of the work — the spindle speed increases as the working diameter decreases. To prevent the spindle speed from increasing beyond a maximum value, the S-word, see *Spindle Function (S-Word)*, is used to specify the maximum allowable spindle speed before issuing the G95 command. If the spindle speed is changed after the G95 is used, the feed rate is also changed accordingly. If G94 is used to set a constant feed per unit of time (inches or millimeters per minute), changes in the spindle speed do not affect the feed rate.

Feed rates expressed in inches or millimeters per revolution can be converted to feed rates in inches or millimeters per minute by multiplying the feed rate by the spindle speed in revolutions per minute: feed/minute = feed/revolution × spindle speed in rpm. Feed rates for milling cutters are sometimes given in inches or millimeters per tooth. To convert feed

www.EngineeringEBooksPdf.com

per tooth to feed per revolution, multiply the feed rate per tooth by the number of cutter teeth: feed/revolution = feed/tooth × number of teeth.

For certain types of cuts, some systems require an inverse-time *feed command* that is the reciprocal of the time in minutes required to complete the block of instructions. The feed command is indicated by a G93 code followed by an F-word value found by dividing the feed rate, in inches (millimeters) or degrees per minute, by the distance moved in the block: feed command = feed rate/distance = (distance/time)/distance = 1/time.

Feed-rate override refers to a control, usually a rotary dial on the control system panel, that allows the programmer or operator to override the programmed feed rate. Feed-rate override does not change the program; permanent changes can only be made by modifying the program. The range of override typically extends from 0 to 150 per cent of the programmed feed rate on CNC machines; older hardwired systems are more restrictive and most cannot be set to exceed 100 per cent of the preset rate.

Spindle Function (S-Word).—An S-word specifies the speed of rotation of the spindle. The spindle function is programmed by the address S followed by the number of digits specified in the format detail (usually a four-digit number). Two G-codes control the selection of spindle speed input: G96 selects a constant cutting speed in surface feet per minute (sfm) or meters per minute (mpm) and G97 selects a constant spindle speed in revolutions per minute (rpm).

In turning, a constant spindle speed (G97) is applied for threading cycles and for machining parts in which the diameter remains constant. Feed rate can be programmed with either G94 (inches or millimeters per minute) or G95 (inches or millimeters per revolution) because each will result in a constant cutting speed to feed relationship.

G96 is used to select a constant cutting speed (i.e., a constant surface speed) for facing and other cutting operations in which the diameter of the workpiece changes. The spindle speed is set to an initial value specified by the S-word and then automatically adjusted as the diameter changes so that a constant surface speed is maintained. The control system adjusts spindle speed automatically, as the working diameter of the cutting tool changes, decreasing spindle speed as the working diameter increasesor increasing spindle speed as the working diameter decreases. When G96 is used for a constant cutting speed, G95 in a succeeding block maintains a constant feed rate per revolution.

Speeds given in surface feet or meters per minute can be converted to speeds in revolutions per minute (rpm) by the formulas:

$$\text{rpm} = \frac{\text{sfm} \times 12}{\pi \times d} \qquad \text{rpm} = \frac{\text{mpm} \times 1000}{\pi \times d}$$

where d is the diameter, in inches or millimeters, of the part on a lathe or of the cutter on a milling machine; and π is equal to 3.14159.

Tool Function (T-Word).—The T-word calls out the tool that is to be selected on a machining center or lathe having an automatic tool changer or indexing turret. On machines without a tool changer, this word causes the machine to stop and request a tool change. This word also specifies the proper turret face on a lathe. The word usually is accompanied by several numbers, as in T0101, where the first pair of numbers refers to the tool number (and carrier or turret if more than one) and the second pair of numbers refers to the tool offset number. Therefore, T0101 refers to tool 1, offset 1.

Information about the tools and the tool setups is input to the CNC system in the form of a *tool data table.* Details of specific tools are transferred from the table to the part program via the T-word. The tool nose radius of a lathe tool, for example, is recorded in the tool data table so that the necessary tool path calculations can be made by the CNC system. The miscellaneous code M06 can also be used to signal a tool change, either manually or automatically.

www.EngineeringEBooksPdf.com

Compensation for variations in the tool nose radius, particularly on turning machines, allows the programmer to program the part geometry from the drawing and have the tool follow the correct path in spite of variations in the tool nose shape. Typical of the data required, as shown in Fig. 4, are the nose radius of the cutter, the *X* and *Z* distances from the gage point to some fixed reference point on the turret, and the orientation of the cutter (tool tip orientation code), as shown in Fig. 5. Details of nose radius compensation for numerical control is given in a separate section (Indexable Insert Holders for NC).

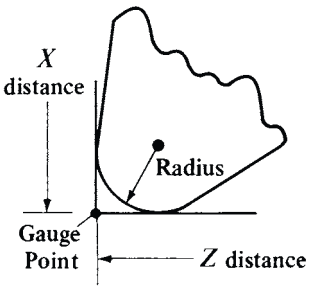

Fig. 4.

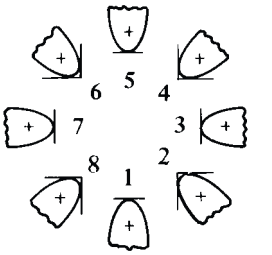

Fig. 5.

Tool offset, also called cutter offset, is the amount of cutter adjustment in a direction parallel to the axis of a tool. Tool offset allows the programmer to accommodate the varying dimensions of different tooling by assuming (for the sake of the programming) that all the tools are identical. The actual size of the tool is totally ignored by the programmer who programs the movement of the tools to exactly follow the profile of theworkpiece shape. Once tool geometry is loaded into the tool data table and the cutter compensation controls of the machine activated, the machine automatically compensates for the size of the tools in the programmed movements of the slide. In gage length programming, the tool length and tool radius or diameter are included in the program calculations. Compensation is then used only to account for minor variations in the setup dimensions and tool size.

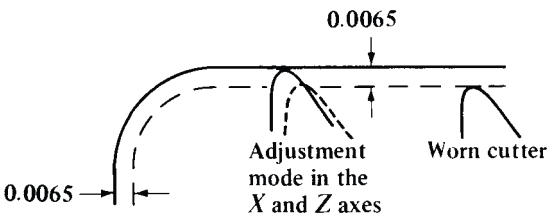

Fig. 6.

Customarily, the tool offset is used in the beginning of a program to initialize each individual tool. Tool offset also allows the machinist to correct for conditions, such as tool wear, that would cause the location of the cutting edge to be different from the programmed location. For example, owing to wear, the tool tip in Fig. 6 is positioned a distance of 0.0065 inch from the location required for the work to be done. To compensate for this wear, the operator (or part programmer), by means of the CNC control panel, adjusts the tool tip with reference to the *X*- and *Z*-axes, moving the tool closer to the work by

www.EngineeringEBooksPdf.com

0.0065 inch throughout its traverse. The tool offset number causes the position of the cutter to be displaced by the value assigned to that offset number.

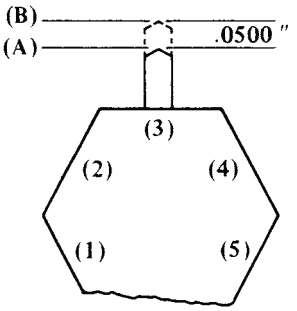

Fig. 7.

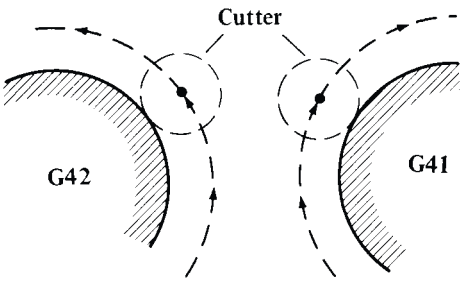

Fig. 8.

Changes to the programmed positions of cutting tool tip(s) can be made by *tool length offset* programs included in the control system. A dial or other means is generally provided on milling, drilling, and boring machines, and machining centers, allowing the operator or part programmer to override the programmed axial, or *Z*-axis, position. This feature is particularly helpful when setting the lengths of tools in their holders or setting a tool in a turret, as shown in Fig. 7, because an exact setting is not necessary. The tool can be set to an approximate length and the discrepancy eliminated by the control system.

The amount of offset may be determined by noting the amount by which the cutter is moved manually to a fixed point on the fixture or on the part, from the programmed *Z*-axis location. For example, in Fig. 7, the programmed *Z*-axis motion results in the cutter being moved to position A, whereas the required location for the tool is at B. Rather than resetting the tool or changing the part program, the tool length offset amount of 0.0500 inch is keyed into the control system. The 0.0500-inch amount is measured by moving the cutter tip manually to position B and reading the distance moved on the readout panel. Thereafter, every time that cutter is brought into the machining position, the programmed *Z*-axis location will be overridden by 0.0500 inch.

Manual adjustment of the cutter center path to correct for any variance between nominal and actual cutter radius is called *cutter compensation.* The net effect is to move the path of the center of the cutter closer to, or away from, the edge of the workpiece, as shown in Fig. 8. The compensation may also be handled via a tool data table.When cutter compensation is used, it is necessary to include in the program a G41 code if the cutter is to be to the left of the part and a G42 code if to the right of the part, as shown in Fig. 8. A G40 code cancels cutter compensation. Cutter compensation with earlier hardwire systems was expensive, very limited, and usually held to ±0.0999 inch. The range for cutter compensation with CNC control systems can go as high as ±999.9999 inches, although adjustments of this magnitude are unlikely to be required.

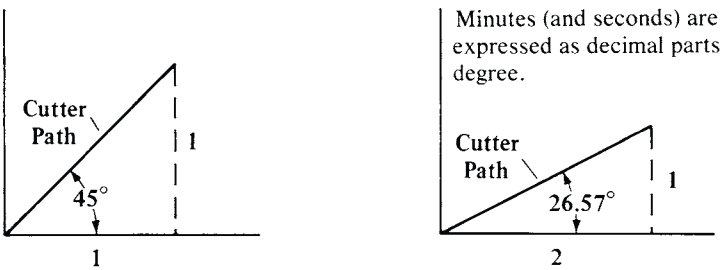

Fig. 9.

Linear Interpolation.—The ability of the control system to guide the workpiece along a straight-line path at an angle to the slide movements is called linear interpolation. Move-

www.EngineeringEBooksPdf.com

ments of the slides are controlled through simultaneous monitoring of pulses by the control system. For example, if monitoring of the pulses for the *X*-axis of a milling machine is at the same rate as for the *Y*-axis, the cutting tool will move at a 45-degree angle relative to the *X*-axis. However, if the pulses are monitored at twice the rate for the *X*-axis as for the *Y*-axis, the angle that the line of travel will make with the *X*-axis will be 26.57 degrees (tangent of 26.57 degrees = ½), as shown in Fig. 9. The data required are the distances traveled in the *X*- and *Y*-directions, and from these data, the control system will generate the straight line automatically. This monitoring concept also holds for linear motions along three axes. The required G-code for linear interpolation blocks is G01. The code is modal, which means that it will hold for succeeding blocks until it is changed.

Circular Interpolation.— A simplified means of programming circular arcs in one plane, using one block of data, is called circular interpolation. This procedure eliminates the need to break the arc into straight-line segments. Circular interpolation is usually handled in one plane, or two dimensions, although three-dimensional circular interpolation is described in the Standards. The plane to be used is selected by a G or preparatory code. In Fig. 10, G17 is used if the circle is to be formed in the *X*–*Y* plane,

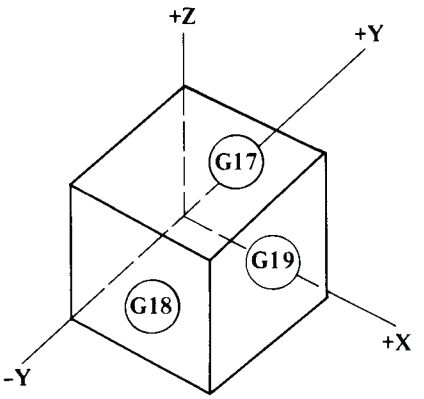

Fig. 10.

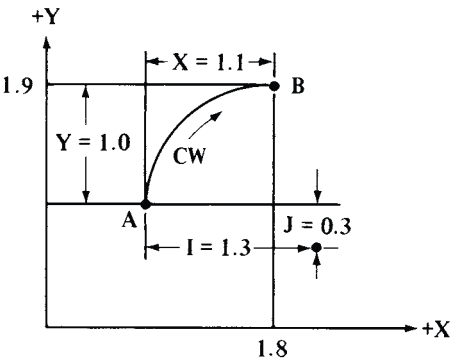

Fig. 11.

G18 if in the *X*–*Z* plane, and G19 if in the *Y*–*Z* plane. Often the control system is preset for the circular interpolation feature to operate in only one plane (e.g., the *X*–*Y* plane for milling machines or machining centers or the *X*–*Z* plane for lathes), and for these machines, the G-codes are not necessary.

A circular arc may be described in several ways. Originally, the RS-274 Standard specified that, with incremental programming, the block should contain:

1) A G-code describing the direction of the arc, G02 for clockwise (CW), and G03 for counterclockwise (CCW).

2) Directions for the component movements around the arc parallel to the axes. In the example shown in Fig. 11, the directions are *X* = +1.1 inches and *Y* = +1.0 inch. The signs are determined by the direction in which the arc is being generated. Here, both *X* and *Y* are positive.

3) The I dimension, which is parallel to the *X*-axis with a value of 1.3 inches, and the J dimension, which is parallel to the *Y*-axis with a value of 0.3 inch. These values, which locate point A with reference to the center of the arc, are called offset dimensions. The block for this work would appear as follows:

N0025 G02 X011000 Y010000 I013000 J003000
(The sequence number, N0025, is arbitrary.)

The block would also contain the plane selection (i.e., G17, G18, or G19), if this selection is not preset in the system. Most of the newer control systems allow duplicate words in the

www.EngineeringEBooksPdf.com

same block, but most of the older systems do not. In these older systems, it is necessary to insert the plane selection code in a separate and prior block, for example, N0020 G17.

Another stipulation in the Standard is that the arc is limited to one quadrant. Therefore, four blocks would be required to complete a circle. Four blocks would also be required to complete the arc shown in Fig. 12, which extends into all four quadrants.

When utilizing absolute programming, the coordinates of the end point are described. Again from Fig. 11, the block, expressed in absolute coordinates, appears as:

N0055 G02 X01800 Y019000 I013000 J003000

where the arc is continued from a previous block; the starting point for the arc in this block would be the end point of the previous block.

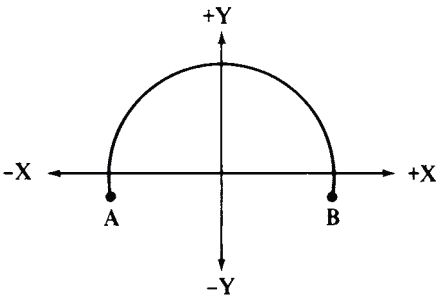

Fig. 12.

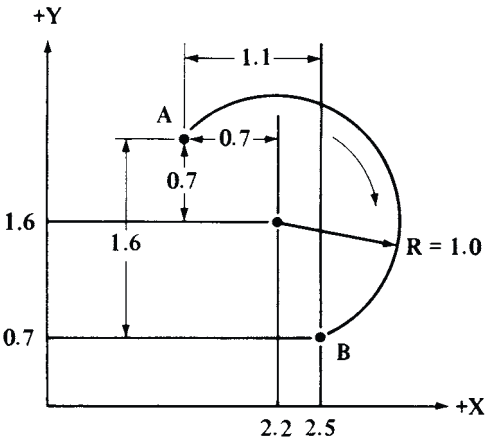

Fig. 13.

The Standard still contains the format discussed, but simpler alternatives have been developed. The latest version of the Standard (RS-274-D) allows *multiple quadrant programming* in one block, by inclusion of a G75 word. In the absolute-dimension mode (G90), the coordinates of the arc center are specified. In the incremental-dimension mode (G91), the signed (plus or minus) incremental distances from the beginning point of the arc to the arc center are given. Most system builders have introduced some variations on this format. One system builder utilizes the center and the end point of the arc when in an absolute mode, and might describe the block for going from A to B in Fig. 13 as:

N0065 G75 G02 X2.5 Y0.7 I2.2 J1.6

The I and the J words are used to describe the coordinates of the arc center. Decimal-point programming is also used here. A block for the same motion when programmed incrementally might appear as:

N0075 G75 G02 X1.1 Y – 1.6 I0.7 J0.7

This approach is more in conformance with the RS-274-D Standard in that the *X* and *Y* values describe the displacement between the starting and ending points (points A and B), and the I and J indicate the offsets of the starting point from the center. Another and even more convenient way of formulating a circular motion block is to note the coordinates of the ending point and the radius of the arc. Using absolute programming, the block for the motion in Fig. 13 might appear as:

N0085 G75 G02 X2.5 Y0.7 R10.0

The starting point is derived from the previous motion block. Multiquadrant circular interpolation is canceled by a G74 code.

Helical and Parabolic Interpolation.—Helical interpolation is used primarily for milling large threads and lubrication grooves, as shown in Fig. 14. Generally, helical interpolation involves motion in all three axes (*X, Y, Z*) and is accomplished by using circular

www.EngineeringEBooksPdf.com

interpolation (G02 or G03) while changing the third dimension. Parabolic interpolation (G06) is simultaneous and coordinated control of motion-such that the resulting cutter path describes part of a parabola. The RS-274-D Standard provides further details.

Subroutine.— A subroutine is a set of instructions or blocks that can be inserted into a program and repeated whenever required. Parametric subroutines permit letters or symbols to be inserted into the program in place of numerical values (see *Parametric Expressions and Macros*). Parametric subroutines can be called during part programming and values assigned to the letters or symbols. This facility is particularly helpful when dealing with families of parts.

A subprogram is similar to a subroutine except that a subprogram is not wholly contained within another program, as is a subroutine. Subprograms are used when it is necessary to perform the same task frequently, in different programs. The advantage of subprograms over subroutines is that subprograms may be called by any other program, whereas the subroutine can only be called by the program that contains the subroutine.

There is no standard subroutine format; however, the example below is typical of a program that might be used for milling the three pockets shown in Fig. 15. In the example, the beginning and end of the subroutine are indicated by the codes M92 and M93, respectively, and M94 is the code that is used to call the subroutine. The codes M92, M93, and M94 are not standardized (M-codes M90 through M99 are reserved for the user) and may be different from control system to control system. The subroutine functions may use different codes or may not be available at all on other systems.

N0010 G00 X.6 Y.85	Cutter is moved at a rapid traverse rate to a position over the corner of the first pocket to be cut.
N0020 M92	Tells the system that the subroutine is to start in the next block.
N0030 G01 Z–.25 F2.0	Cutter is moved axially into the workpiece 0.25 inch at 2.0 ipm.
N0040 X.8	Cutter is moved to the right 0.8 inch.
N0050 Y.2	Cutter is moved laterally up 0.2 inch.
N0060 X–.8	Cutter is moved to the left 0.8 inch.
N0070 Y.2	Cutter is moved laterally up 0.2 inch.

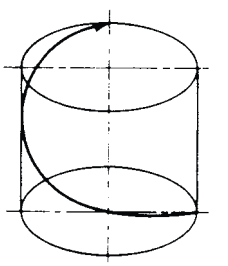

Fig. 14.

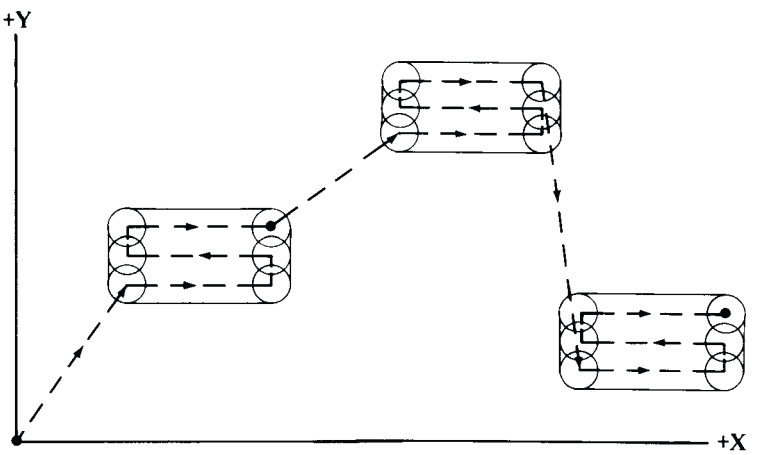

Fig. 15.

www.EngineeringEBooksPdf.com

N0080 X.8	Cutter is moved to the right 0.8 inch.
N0090 G00 Z.25 M93	Cutter is moved axially out of pocket at rapid traverse rate. Last block of subroutine is signaled by word M93.
N0100 X.75 Y.5	Cutter is moved to bottom left-hand corner of second pocket at rapid traverse rate.
N0110 M94 N0030	Word M94 calls for repetition of the subroutine that starts at sequence number N0030 and ends at sequence number N0090.
N0120 G00 X.2 Y–I.3	After the second pocket is cut by repetition of sequence numbers N0030 through N0090, the cutter is moved to start the third pocket.
N0130 M94 N0030	Repetition of subroutine is called for by word M94 and the third pocket is cut.

Parametric Expressions and Macros.—Parametric programming is a method whereby a variable or replaceable parameter representing a value is placed in the machining code instead of using the actual value. In this manner, a section of code can be used several or many times with different numerical values, thereby simplifying the programming and reducing the size of the program. For example, if the values of X and Y in lines N0040 to N0080 of the previous example are replaced as follows:

N0040 X#1

N0050 Y#2

N0060 X#3

N0070 Y#4

then the subroutine starting at line N0030 is a parametric subroutine. That is, the numbers following the # signs are the variables or parameters that will be replaced with actual values when the program is run. In this example, the effect of the program changes is to allow the same group of code to be used for milling pockets of different sizes. If on the other hand, lines N0010, N0100, and N0120 of the original example were changed in a similar manner, the effect would be to move the starting location of each of the slots to the location specified by the replaceable parameters.

Before the program is run, the values that are to be assigned to each of the parameters or variables are entered as a list at the start of the part program in this manner:

#1 = .8

#2 = .2

#3 = .8

#4 = .2

All that is required to repeat the same milling process again, but this time creating a different size pocket, is to change the values assigned to each of the parameters #1, #2, #3, and #4 as necessary. Techniques for using parametric programming are not standardized and are not recognized by all control systems. For this reason, consult the programming manual of the particular system for specific details.

www.EngineeringEBooksPdf.com

As with a parametric subroutine, macro describes a type of program that can be recalled to allow insertion of finite values for letter variables. The difference between a macro and a parametric subroutine is minor. The term macro normally applies toa source program that is used with computer-assisted part programming; the parametric subroutine is a feature of the CNC system and can be input directly into that system.

Conditional Expressions.—It is often useful for a program to make a choice between two or more options, depending on whether or not a certain condition exists. A program can contain one or more blocks of code that are not needed every time the program is run, but are needed some of the time. For example, refer to the previous program for milling three slots. An occasion arises that requires that the first and third slots be milled, but not the second one. If the program contained the following block of code, the machine could be easily instructed to skip the milling of the second slot:

N0095 IF [#5 EQ 0] GO TO N0120

In this block, #5 is the name of a variable; EQ is a conditional expression meaning *equals;* and GO TO is a branch statement meaning resume execution of the program at the following line number. The block causes steps N0100 and N0110 of the program to be skipped if the value of #5 (a dummy variable) is set equal to zero. If the value assigned to #5 is any number other than zero, the expression (#5 EQ 0) is not true and the remaining instructions in block N0095 are not executed. Program execution continues with the next step, N0100, and the second pocket is milled. For the second pocket to be milled, parameter #5 is initialized at the beginning of the program with a statement such as #5 = 1 or #5 = 2. Initializing #5 = 0 guarantees that the pocket is not machined. On control systems that automatically initialize all variables to zero whenever the system is reset or a program is loaded, the second slot will not be machined unless the #5 is assigned a nonzero value each time the program is run.

Other conditional expressions are: NE = not equal to; GT = greater than; LT = less than; GE = greater than or equal to; and LE = less than or equal to. As with parametric expressions, conditional expressions may not be featured on all machines and techniques and implementation will vary. Therefore, consult the control system programming manual for the specific command syntax.

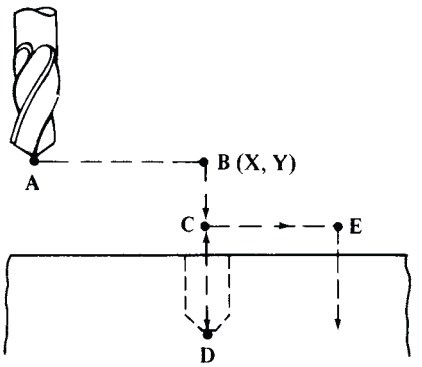
Fixed (Canned) Cycles.—Fixed (canned) cycles comprise sets of instructions providing for a preset sequence of events initiated by a single command or a block of data. Fixed cycles generally are offered by the builder of the control system or machine tool as part of the software package that accompanies the CNC system. Limited numbers of canned cycles began to appear on hardwire control systems shortly before their demise. The canned cycles offered generally consist of the standard G-codes covering driling, boring, and tapping operations, plus options that have been developed by the system builder such as thread cutting and turning cycles. (See *Thread Cutting* and *Turning Cycles*.) Some standard canned cycles included in RS-274-D are shown herewith. A block of data that might be used to generate the cycle functions is also shown above each illustration. Although the G-codes for the functions are standardized, the other words in the block and the block format are not, and different control system builders have different arrangements. The blocks shown are reasonable examples of fixed cycles and do not represent those of any particular system builder.

www.EngineeringEBooksPdf.com

The G81 block for a simple drilling cycle is:

N_____ G81 X_____Y_____C_____D_____F_____EOB

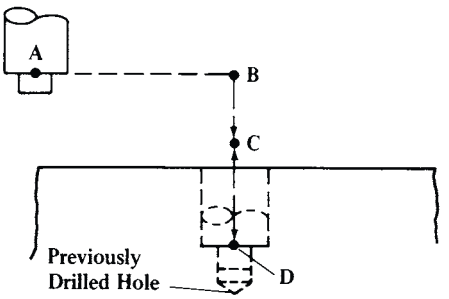
N_____X_____Y_____EOB



This G81 drilling cycle will move the drill point from position A to position B and then down to C at a rapid traverse rate; the drill point will next be fed from C to D at the programmed feed rate, then returned to C at the rapid traverse rate. If the cycle is to be repeated at a subsequent point, such as point E in the illustration, it is necessary Only to give the required X and Y coordinates. This repetition capability is typical of canned cycles.

The G82 block for a spotfacing or drilling cycle with a dwell is:

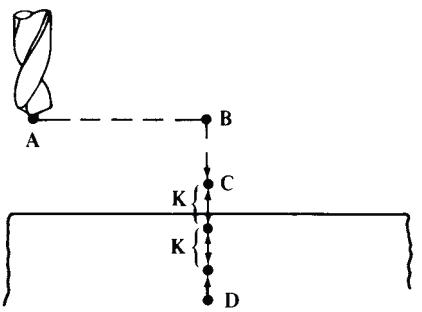
N_____G82 X_____Y_____C_____D_____T_____F_____EOB



This G82 code produces a cycle that is very similar to the cycle of the G81 code except for the dwell period at point D. The dwell period allows the tool to smooth out the bottom of the counterbore or spotface. The time for the dwell, in seconds, is noted as a T-word.

The G83 block for a peck-drilling cyle is:

N_____G83 X_____Y_____C_____D_____K_____F_____EOB



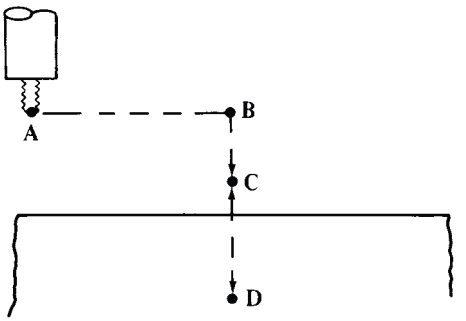
In the G83 peck-drilling cycle, the drill is moved from point A to point B and then to point C at the rapid traverse rate; the drill is then fed the incremental distance K, followed by

www.EngineeringEBooksPdf.com

rapid return to C. Down feed again at the rapid traverse rate through the distance K is next, after which the drill is fed another distance K. The drill is thenrapid traversed back to C, followed by rapid traverse for a distance of K + K; down feed to D follows before the drill is rapid traversed back to C, to end the cycle.

The G84 block for a tapping cycle is:

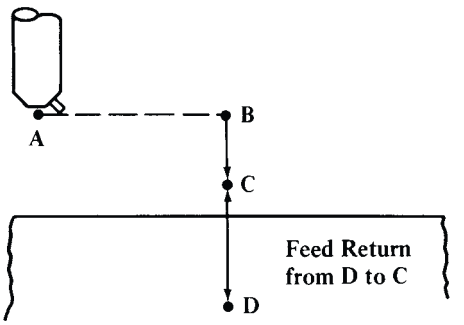
N_____G84 X_____Y_____C_____D_____F_____EOB



The G84 canned tapping cycle starts with the end of the tap being moved from point A to point B and then to point C at the rapid traverse rate. The tap is then fed to point D, reversed, and moved back to point C.

The G85 block for a boring cycle with tool retraction at the feed rate is:

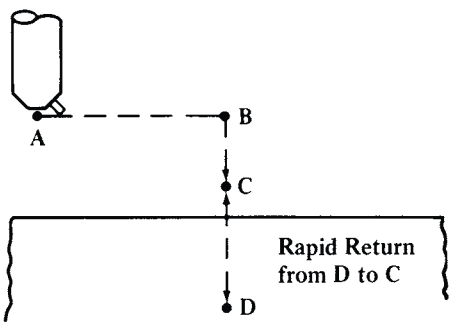
N_____G85 X_____Y_____C_____D_____F_____EOB



In the G85 boring cycle, the tool is moved from point A to point B and then to point C at the rapid traverse rate. The tool is next fed to point D and then, while still rotating, is moved back to point C at the same feed rate.

The G86 block for a boring cycle with rapid traverse retraction is:

N_____G86 X_____Y_____C_____D_____F_____EOB

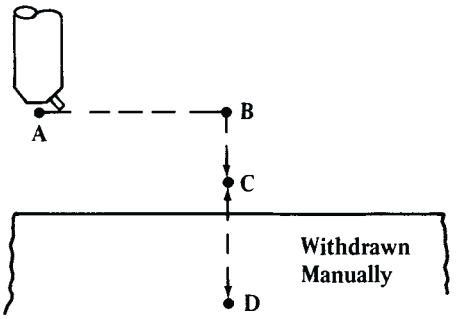


The G86 boring cycle is similar to the G85 cycle except that the tool is withdrawn at the rapid traverse rate.

www.EngineeringEBooksPdf.com

The G87 block for a boring cycle with manual withdrawal of the tool is:

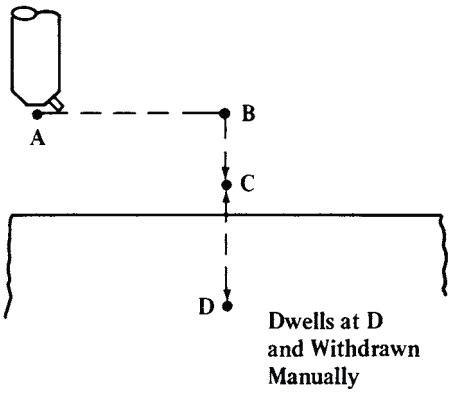
N_____G87 X_____Y_____C_____D_____F_____EOB



In the G87 canned boring cycle, the cutting tool is moved from A to B and then to C at the rapid traverse rate. The tool is then fed to D. The cycle is identical to the other boring cycles except that the tool is withdrawn manually.

The G88 block for a boring cycle with dwell and manual withdrawal is:

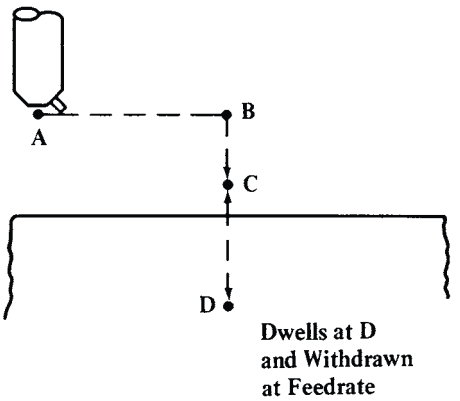
N_____G88 X_____Y_____C_____D_____T_____F_____EOB



In the G88 dwell cycle, the tool is moved from A to B to C at the rapid traverse rate and then fed at the prescribed feed rate to D. The tool dwells at D, then stops rotating and is withdrawn manually.

The G89 block for a boring cycle with dwell and withdrawal at the feed rate is:

N_____G89 X_____Y_____C_____D_____T_____F_____EOB



www.EngineeringEBooksPdf.com

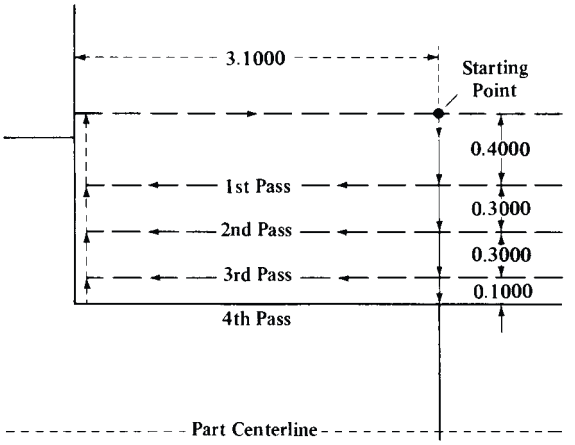


Fig. 16.

Turning Cycles.—Canned turning cycles are available from most system builders and are designed to allow the programmer to describe a complete turning operation in one or a few blocks. There is no standard for this type of operation, so a wide variety of programs have developed. Fig. 16 shows a hypothetical sequence in which the cutter is moved from the start point to depth for the first pass. If incremental programming is in effect, this distance is specified as D1. The depths of the other cuts will also be programmed as D2, D3, and so on. The length of the cut will be set by the W-word, and will remain the same with each pass. The preparatory word that calls for the roughing cycle is G77. The roughing feed rate is 0.03 ipr (inch per revolution), and the finishing feed rate (last pass) is 0.005 ipr. The block appears as follows:

N0054 G77 W = 3.1 D1 = .4 D2 = .3 D3 = .3 D4 = .1 F1 = .03 F2 = .005

Thread Cutting.—Most NC lathes can produce a variety of thread types including constant-lead threads, variable-lead threads (increasing), variable-lead threads (decreasing), multiple threads, taper threads, threads running parallel to the spindle axis, threads (spiral groove) perpendicular to the spindle axis, and threads containing a combination of the preceding. Instead of the feed rate, the lead is specified in the threading instruction block, so that the feed rate is made consistent with, and dependent upon, the selected speed (rpm) of the spindle.

The thread lead is generally noted by either an I- or a K-word. The I-word is used if the thread is parallel to the *X*-axis and the K-word if the thread is parallel to the *Z*-axis, the latter being by far the most common. The G-word for a constant-lead thread is G33, for an increasing variable-lead thread is G34, and for a decreasing variable-lead thread is G35. Taper threads are obtained by noting the *X*- and *Z*-coordinates of the beginning and end points of the thread if the G90 code is in effect (absolute programming), or the incremental movement from the beginning point to the end point of the thread if the G91 code (incremental programming) is in effect.

N0001 G91	(Incremental programming)
N0002 G00 X–.1000	(Rapid traverse to depth)
N0003 G33 Z–1.0000 K.0625	(Produce a thread with a constant lead of 0.625 inch)
N0004 G00 X.1000	(Withdraw at rapid traverse)
N0005 Z1.0000	(Move back to start point)

www.EngineeringEBooksPdf.com

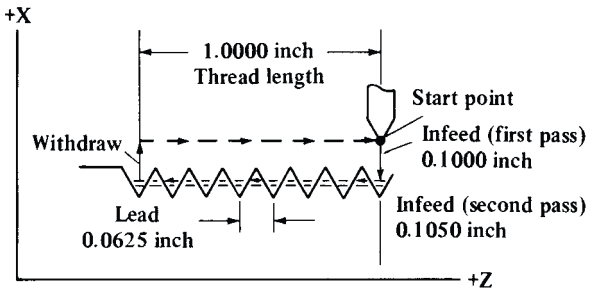

Fig. 17.

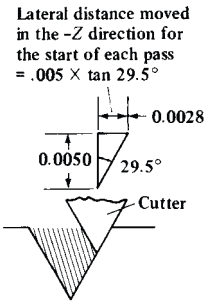

Fig. 18.

Multiple threads are specified by a code in the block that spaces the start of the threads equally around the cylinder being threaded. For example, if a triple thread is to be cut, the threads will start 120 degrees apart. Typical single-block thread cutting utilizing a plunge cut is illustrated in Fig. 17 and shows two passes. The passes areidentical except for the distance of the plunge cut. Builders of control systems and machine tools use different codewords for threading, but those shown below can be considered typical. For clarity, both zeros and decimal points are shown.

The only changes in the second pass are the depth of the plunge cut and the withdrawal. The blocks will appear as follows:

N0006 X – .1050
N0007 G33 Z – 1.0000 K.0625
N0008 G00 X.1050
N0009 Z1.000

Compound thread cutting, rather than straight plunge thread cutting, is possible also, and is usually used on harder materials. As illustrated in Fig. 18, the starting point for the thread is moved laterally in the -Z direction by an amount equal to the depth of the cut times the tangent of an angle that is slightly less than 30 degrees. The program for the second pass of the example shown in Fig. 18 is as follows:

N0006 X – .1050 Z – .0028
N0007 G33 Z – 1.0000 K.0625
N0008 G00 X.1050
N0009 Z1.0000

Fixed (canned), one-block cycles also have been developed for CNC systems to produce the passes needed to complete a thread. These cycles may be offered by the builder of the control system or machine tool as standard or optional features. Subroutines also can generally be prepared by the user to accomplish the same purpose (see Subroutine). A one-block fixed threading cycle might look something like:

N0048 G98 X – .2000 Z – 1.0000 D.0050 F.0010

where G98 = preparatory code for the threading cycle
X–.2000 = total distance from the starting point to the bottom of the thread
Z–1.0000 = length of the thread
D.0050 = depths of successive cuts
F.0010 = depth(s) of the finish cut(s)

APT Programming

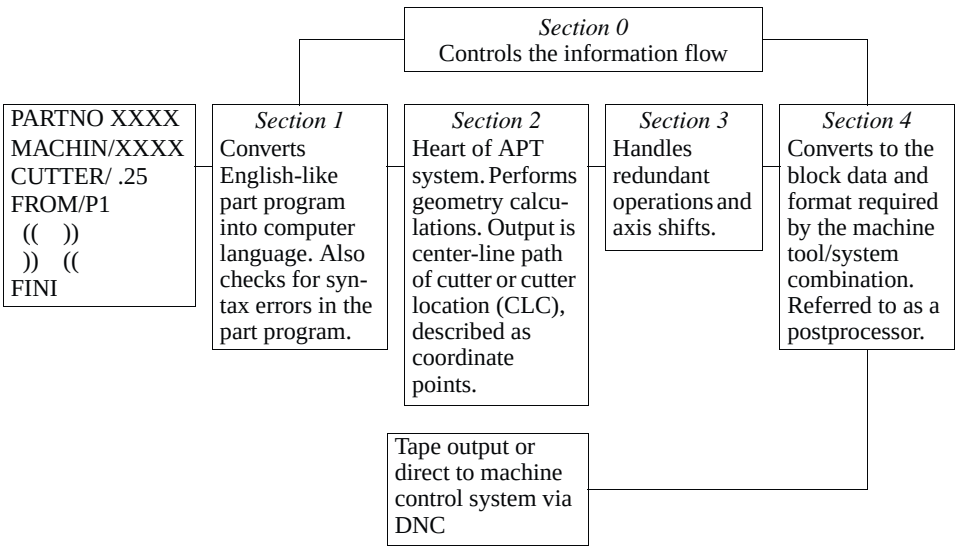
APT.—APT stands for Automatically Programmed Tool and is one of many computer languages designed for use with NC machine tools. The selection of a computer-assisted part-programming language depends on the type and complexity of the parts being machined more than on any other factor. Although some of the other languages may be easier to use, APT has been chosen to be covered in this book because it is a nonproprietary

www.EngineeringEBooksPdf.com

language in the public domain, has the broadest range of capability, and is one of the most advanced and universally accepted NC programming languages available. APT (or a variation thereof) is also one of the languages that is output by many computer programs that produce CNC part programs directly from drawings produced with CAD systems.

APT is suitable for use in programming part geometry from simple to exceptionally complex shapes. APT was originally designed and used on mainframe computers, however, it is now available, in many forms, on mini- and microcomputers as well. APT has also been adopted as ANSI Standard X3.37and by the International Organization for Standardization (ISO) as a standardized language for NC programming. APT is a very dynamic program and is continually being updated. APT is being used as a processor for part-programming graphic systems, some of which have the capability of producing an APT program from a graphic screen display or CAD drawing and of producing a graphic display on the CAD system from an APT program.

APT is a high-level programming language. One difference between APT and the ANSI/EIA RS-274-D (G-codes) programming format discussed in the last section is that APT uses English like words and expressions to describe the motion of the tool or workpiece. APT has the capability of programming the machining of parts in up to five axes, and also allows computations and variables to be included in the programming statements so that a whole family of similar parts can be programmed easily. This section describes the general capabilities of the APT language and includes a ready reference guide to the basic geometry and motion statements of APT, which is suitable for use in programming the machining of the majority of cubic type parts involving two-dimensional movements. Some of the three-dimensional geometry capability of APT and a description of its five-dimensional capability are also included.



As shown above, the APT system can be thought of comprising the input program, the five sections 0 through IV, and the output program. The input program shown on the left progresses through the first four sections and all four are controlled by the fifth, section 0. Section IV, the postprocessor, is the software package that is added to sections II and III to customize the output and produce the necessary program format (including the G-words, M-words, etc.) so that the coded instructions will be recognizable by the control system. The postprocessor is software that is separate from the main body of the APT program, but for purposes of discussion, it may be easier to consider it as a unit within the APT program.

www.EngineeringEBooksPdf.com

APT Computational Statements.— Algebraic and trigonometric functions and computations can be performed with the APT system as follows:

Arithmetic Form	APT Form	Arithmetic Form	APT Form	Arithmetic Form	APT Form
25×25	25*25	25^2	25**2	$\cos \theta$	COSF(θ)
$25 \div 25$	25/25	25^n	25**n	$\tan \theta$	TANF(θ)
25 + 25	25 + 25	$\sqrt{25}$	SQRTF (25)	arctan .5000	ATANF(.5)
25 – 25	25 – 25	$\sin \theta$	SINF(θ)		

Computations may be used in the APT system in two ways. One way is to let a factor equal the computation and then substitute the factor in a statement; the other is to put the computation directly into the statement. The following is a series of APT statements illustrating the first approach.

```
P1 = POINT/0,0,1
 T = (25*2/3 + (3**2 – 1))
P2 = POINT/T,0,0
```

The second way would be as follows;

```
P1 = POINT/0,0,1
P2 = POINT/(25*2/3 + (3**2 – 1)),0,0
```

Note: The parentheses have been used as they would be in an algebraic formula so that the calculations will be carried out in proper sequence. The operations within the inner parentheses would be carried out first. It is important for the total number of left-hand parentheses to equal the total number of right-hand parentheses; otherwise, the program will fail.

APT Geometry Statements.— Before movements around the geometry of a part can be described, the geometry must be defined. For example, in the statement GOTO/P1, the computer must know where P1 is located before the statement can be effective. P1 therefore must be described in a geometry statement, prior to its use in the motion statement GOTO/P1. The simplest and most direct geometry statement for a point is

```
P1 = POINT/X ordinate, Y ordinate, Z ordinate
```

If the *Z* ordinate is zero and the point lies on the *X*–*Y* plane, the *Z* location need not be noted. There are other ways of defining the position of a point, such as at the intersection of two lines or where a line is tangent to a circular arc. These alternatives are described below, together with ways to define lines and circles. Referring to the preceding statement, P1 is known as a symbol. Any combination of letters and numbers may be used as a symbol providing the total does not exceed six characters and at least one of them is a letter. MOUSE2 would be an acceptable symbol, as would CAT3 or FRISBE. However, it is sensible to use symbols that help define the geometry. For example, C1 or CIR3 would be good symbols for a circle. A good symbol for a vertical line would be VL5.

Next, and after the equal sign, the particular geometry is noted. Here, it is a POINT. This word is a vocabulary word and must be spelled exactly as prescribed. Throughout, the designers of APT have tried to use words that are as close to English as possible. A slash follows the vocabulary word and is followed by a specific description of the particular geometry, such as the coordinates of the point P1. A usable statement for P1 might appear as P1 = POINT/1,5,4. The 1 would be the *X* ordinate; the 5, the *Y* ordinate; and the 4, the *Z* ordinate.

Lines as calculated by the computer are infinitely long, and circles consist of 360 degrees. As the cutter is moved about the geometry under control of the motion statements, the lengths of the lines and the amounts of the arcs are "cut" to their proper size. (Some of the geometry statements shown in the accompanying illustrations for defining POINTS, LINES, CIRCLES, TABULATED CYLINDERS, CYLINDERS, CONES, and SPHERES, in the APT language, may not be included in some two-dimensional [ADAPT] systems.)

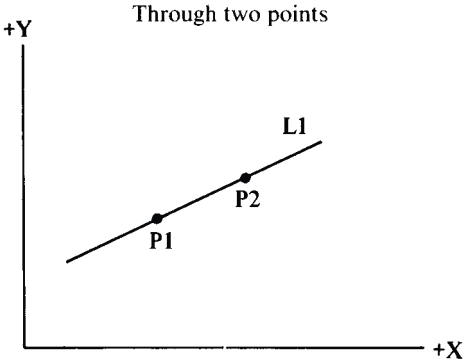
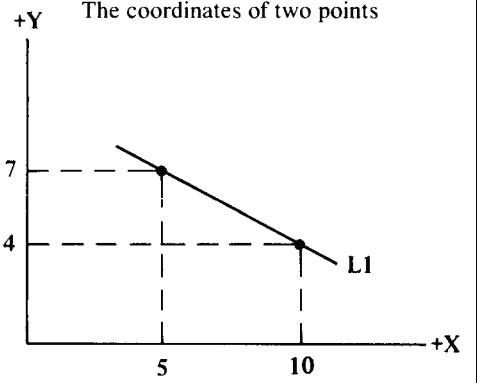
Lines

Through two points



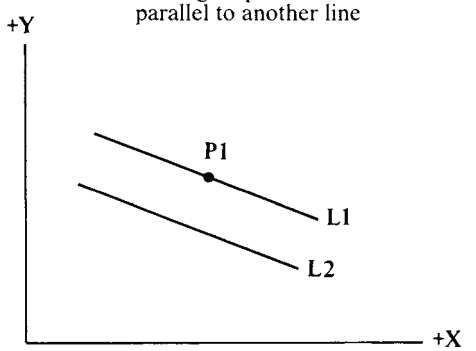
L1 = LINE/P1, P2

The coordinates of two points



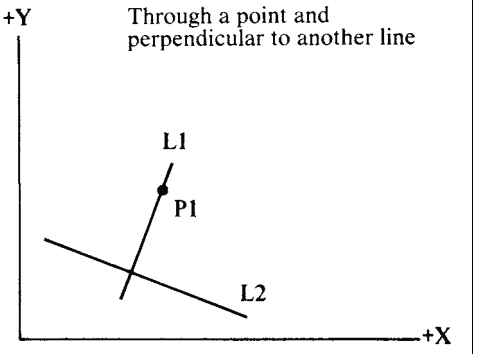
L1 = LINE/5, 7, 10, 4

Through a point and parallel to another line



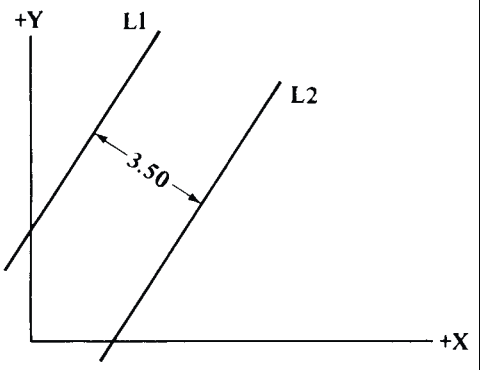
L1 = LINE/P1, PARLEL, L2

Through a point and perpendicular to another line



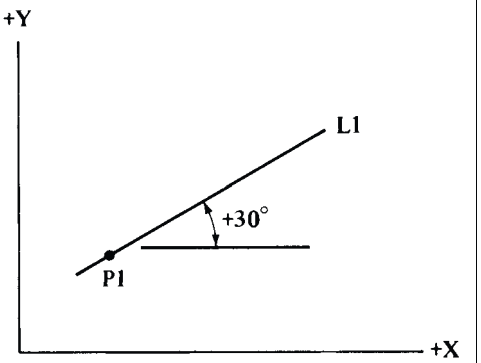
L1 = LINE/P1, PERPTO, L2

A parallel line and a perpendicular distance



L1 = LINE/PARLEL, L2, XSMALL, 3.50
or
L1 = LINE/PARLEL, L2, YLARGE, 3.50
L2 = LINE/PARLEL, L1, XLARGE, 3.50
or
L2 = LINE/PARLEL, L1, YSMALL, 3.50

Through a point and at an angle with X-axis

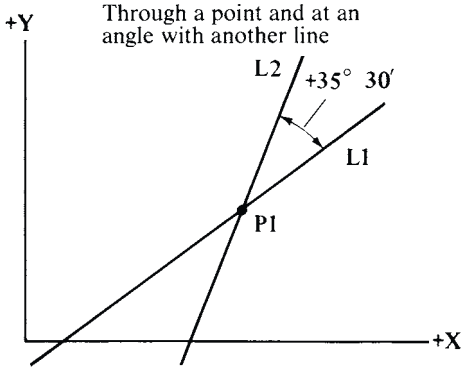


L1 = LINE/P1, ATANGL, 30

www.EngineeringEBooksPdf.com

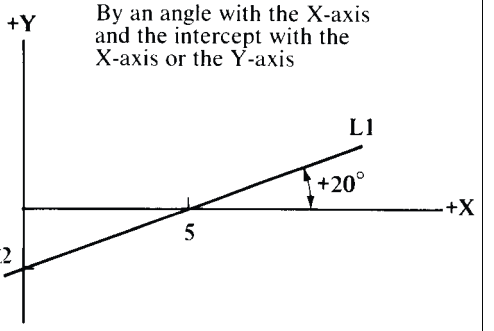
Lines

Through a point and at an angle with another line



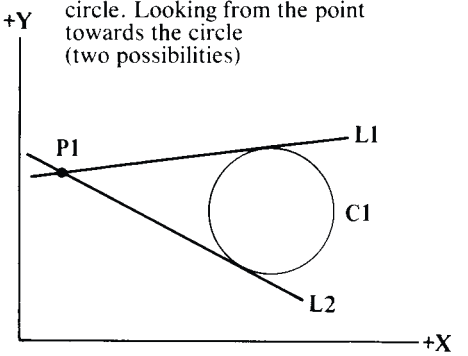
L2 = LINE/P1, ATANGL, 35.5, L1

By an angle with the X-axis and the intercept with the X-axis or the Y-axis



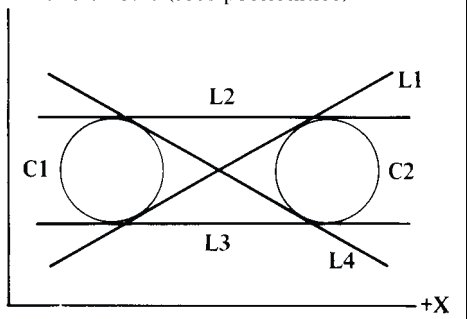
L1 = LINE/ATANGL, 20, INTERC, XAXIS, 5
L1 = LINE/ATANGL, 20, INTERC, YAXIS, 2

Through a point and tangent to a circle. Looking from the point towards the circle (two possibilities)



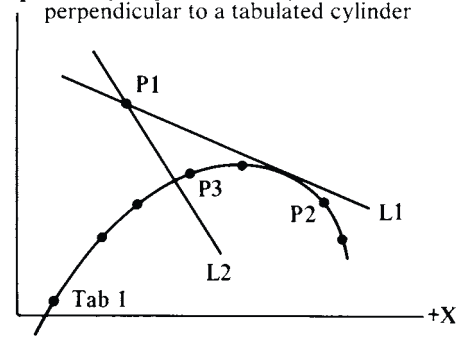
L1 = LINE/P1, LEFT, TANTO, C1
L2 = LINE/P1, RIGHT, TANTO, C1

Tangent to two circles. Looking from the first circle noted in the statement towards the second circle noted (four possibilities)



L1 = LINE/RIGHT, TANTO, C2, LEFT, TANTO, C1
or
L1 = LINE/RIGHT, TANTO, C1, LEFT, TANTO, C2
L2 = LINE/LEFT, TANTO, C1, LEFT, TANTO, C2
or
L2 = LINE/RIGHT, TANTO, C2, RIGHT, TANTO, C1
L3 = LINE/RIGHT, TANTO, C1, RIGHT, TANTO, C2
or
L3 = LINE/LEFT, TANTO, C2, LEFT, TANTO, C1
L4 = LINE/LEFT, TANTO, C2, RIGHT, TANTO, C1
or
L4 = LINE/LEFT, TANTO, C1, RIGHT, TANTO, C2

Through a point and tangent or perpendicular to a tabulated cylinder



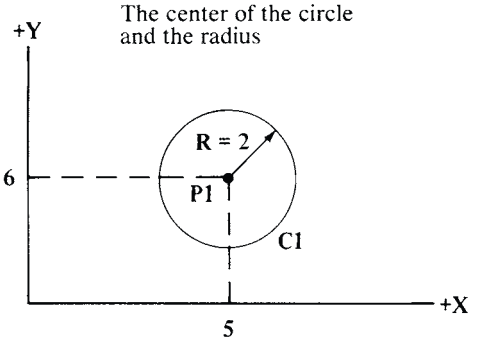
L1 = LINE/P1, TANTO, TAB1, P3
L1 = LINE/P1, PERPTO, TAB1, P3

P2 and P3 are points close to the tangent points of L1 and the intersection point of L2, therefore cannot be end points of the tabulated cylinder

www.EngineeringEBooksPdf.com

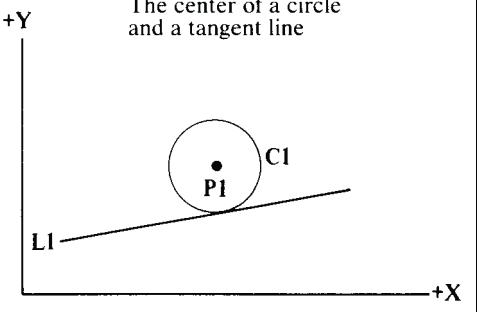
Circles

The center of the circle and the radius



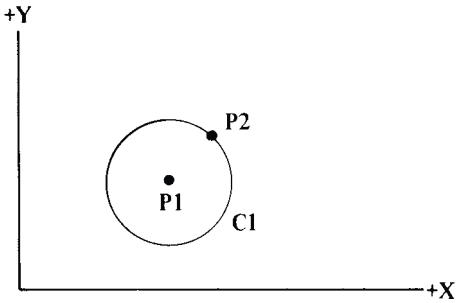
C1 = CIRCLE/5, 6, 2
or
C1 = CIRCLE/5, 6, 0, 2
(where 0 = Z ordinate)
or
C1 = CIRCLE/CENTER, P1, RADIUS, 2

The center of a circle and a tangent line



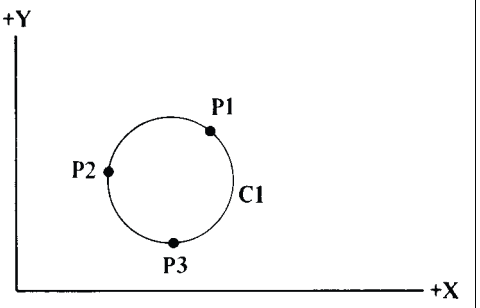
C1 = CIRCLE/CENTER, P1, TANTO, L1

The center of a circle and a point on the circumference



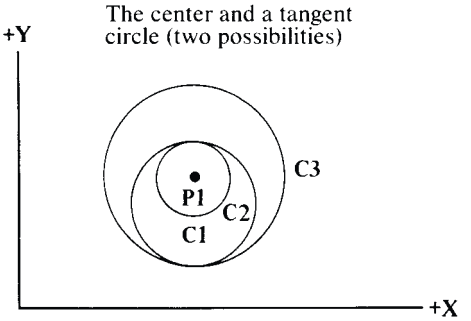
C1 = CIRCLE/CENTER, P1, P2

Three points on a circle



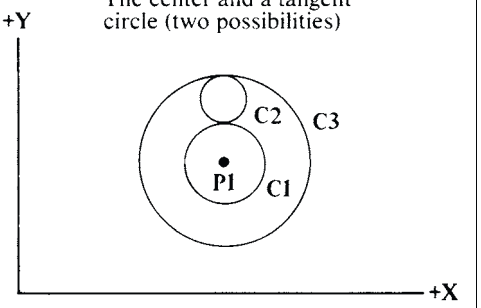
C1 = CIRCLE/P1, P2, P3

The center and a tangent circle (two possibilities)



C1 = CIRCLE/CENTER, P1, SMALL, TANTO, C2
or
C3 = CIRCLE/CENTER, P1, LARGE, TANTO, C2

The center and a tangent circle (two possibilities)

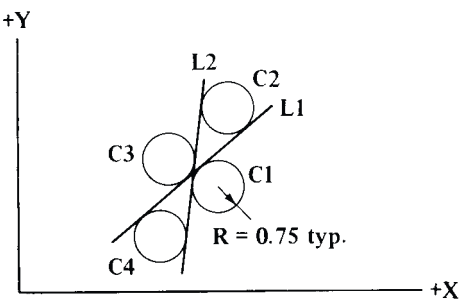


C1 = CIRCLE/CENTER, P1, SMALL, TANTO, C2
or
C3 = CIRCLE/CENTER, LARGE, TANTO, C2

www.EngineeringEBooksPdf.com

Circles

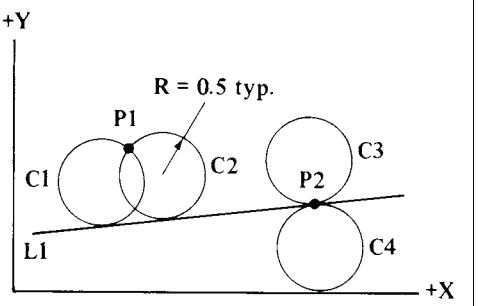
Tangent to two intersecting lines, given the radius (four possibilities)



C1 = CIRCLE/XLARGE, L2, YSMALL, L1, RADIUS, .75
or
C2 = CIRCLE/XLARGE, L2, YLARGE, L1, RADIUS, .75
or
C3 = CIRCLE/XSMALL, L2, YLARGE, L1, RADIUS, .75
or
C4 = CIRCLE/XSMALL, L2, YSMALL, L1, RADIUS, .75

The modifiers (XLARGE, etc.) are used to indicate which of the four circles is wanted.

Tangent to a line and a point on the circumference, given the radius (two possibilities)



C1 = CIRCLE/TANTO, L1, XSMALL, P1, RADIUS, .5
or
C2 = CIRCLE/TANTO, L1, XLARGE, P1, RADIUS, .5
if the point lies on the line, then:
C3 = CIRCLE/TANTO, L1, YLARGE, P2, RADIUS, .5
or
C4 = CIRCLE/TANTO, L1, YSMALL, P2, RADIUS, .5

APT Motion Statements.— APT is based on the concept that a milling cutter is guided by two surfaces when in a contouring mode. Examples of these surfaces are shown in Fig. 1, and they are called the "part" and the "drive" surfaces. Usually, the partsurface guides the bottom of the cutter and the drive surface guides the side of the cutter. These surfaces may or may not be actual surfaces on the part, and although they may be imaginary to the part programmer, they are very real to the computer. The cutter is either stopped or redirected by a third surface called a check surface. If one were to look directly down on these surfaces, they would appear as lines, as shown in Figs. 2a through 2c.

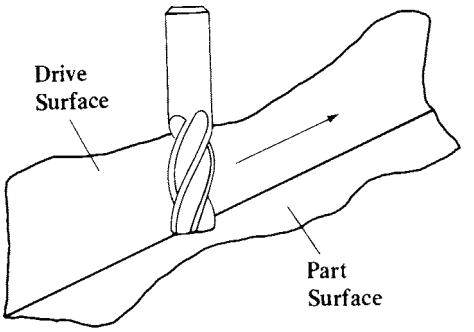


Fig. 1. Contouring Mode Surfaces

When the cutter is moving toward the check surface, it may move to it, onto it, or past it, as illustrated in Fig. 2a. When the cutter meets the check surface, it may go right, denoted by the APT command GORGT, or go left, denoted by the command GOLFT, in Fig. 2b.

www.EngineeringEBooksPdf.com

Alternatively, the cutter may go forward, instructed by the command GOFWD, as in Fig. 2c. The command GOFWD is used when the cutter is moving either onto or off a tangent circular arc. These code instructions are part of what are called motion commands. Fig. 3 shows a cutter moving along a drive surface, L1, toward a check surface, L2. When it arrives at L2, the cutter will make a right turn and move along L2 and past the new check surface L3. Note that L2 changes from a check surface to a drive surface the moment the cutter begins to move along it. The APT motion statement for this move is:

GORGT/L2,PAST,L3

Contouring Cutter Movements

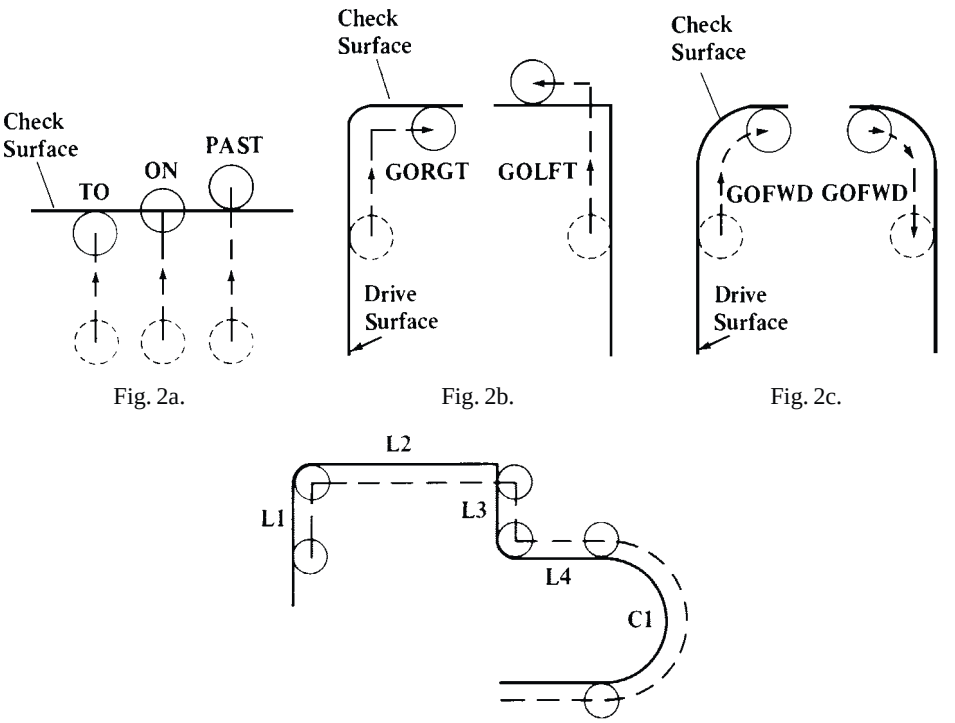

Fig. 2a. Fig. 2b. Fig. 2c.

Fig. 3. Motion Statements for Movements Around a Workpiece

Still referring to Fig. 3, the cutter moves along L3 until it comes to L4. L3 now becomes the drive surface and L4 the check surface. The APT statement is:

GORGT/L3,TO,L4

The next statement is:

GOLFT/L4,TANTO,C1

Even though the cutter is moving to the right, it makes a left turn if one is looking in the direction of travel of the cutter. In writing the motion statements, the part programmers must imagine they are steering the cutter. The drive surface now becomes L4 and the check surface, C1. The next statement will therefore be:

GOFWD/C1,TANTO,L5

This movement could continue indefinitely, with the cutter being guided by the drive, part, and check surfaces.

Start-Up Statements: For the cutter to move along them, it must first be brought into contact with the three guiding surfaces by means of a start-up statement. There are three different start-up statements, depending on how many surfaces are involved.

A three-surface start-up statement is one in which the cutter is moved to the drive, part, and check surfaces, as seen in Fig. 4a. A two-surface start-up is one in which the cutter is

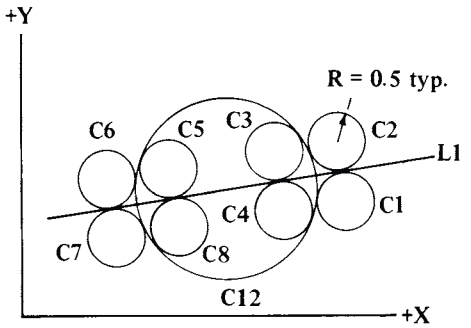
www.EngineeringEBooksPdf.com

moved to the drive and part surfaces, as in Fig. 4b. A one-surface start-up is one in which the cutter is moved to the drive surface and the X–Y plane, where $Z = 0$, as in Fig. 4c. With the two- and one-surface start-up statements, the cutter moves in the most direct path, or perpendicular to the surfaces. Referring to Fig. 4a(three-surface start-up), the move is initiated from a point P1. The two statements that will move the cutter from P1 to the three surfaces are:

FROM/P1
GO/TO,DS,TO,PS,TO,CS

Circles

Tangent to a line and a circle, given the radius (eight possibilities)

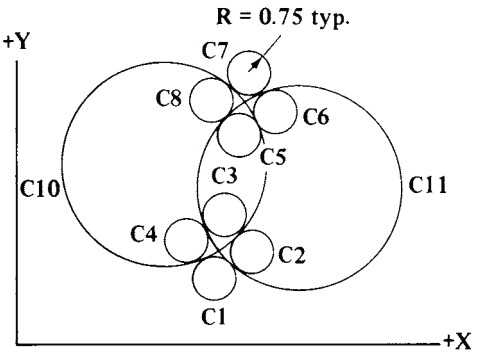


C1 = CIRCLE/YSMALL, L1, XLARGE, OUT, C12, RADIUS, .5
C2 = CIRCLE/YLARGE, L1, XLARGE, OUT, C12, RADIUS, .5
C3 = CIRCLE/YLARGE, L1, XLARGE, IN, C12, RADIUS, .5
C4 = CIRCLE/YSMALL, L1, XLARGE, IN, C12, RADIUS, .5
C5 = CIRCLE/YLARGE, L1, XSMALL, OUT, C12, RADIUS, .5
C6 = CIRCLE/XLARGE, L1, XSMALL, OUT, C12, RADIUS, .5
C7 = CIRCLE/YSMALL, L1, XSMALL, OUT, C12, RADIUS, .5
C8 = CIRCLE/YSMALL, L1, XSMALL, IN, C12, RADIUS, .5

Recommendations:

1. Note which side of line circle is on (e.g., YSMALL, L1).
2. Note whether the circle being defined is inside (IN), or outside (OUT), the known circle.
3. Of the two remaining circles, note whether the circle to be defined is XLARGE, XSMALL, or YLARGE or YSMALL, to arrive at the second modifier in the statement.

Tangent to two circles, given the radius (eight possibilities)



C1 = CIRCLE/YSMALL, OUT, C10, OUT, C11, RADIUS, .75
C2 = CIRCLE/YSMALL, OUT, C10, IN, C11, RADIUS, .75
C3 = CIRCLE/YSMALL, IN, C10, IN, C11, RADIUS, .75
C4 = CIRCLE/YSMALL, IN, C10, OUT, C11, RADIUS, .75
C5 = CIRCLE/YLARGE, IN, C10, IN, C11, RADIUS, .75
C6 = CIRCLE/YLARGE, OUT, C10, IN, C11, RADIUS, .75
C7 = CIRCLE/YLARGE, OUT, C10, OUT, C11, RADIUS, .75
C8 = CIRCLE/YLARGE, IN, C10, OUT, C11, RADIUS, .75

Recommendations

1. Apply IN, OUT modifiers.
2. Apply XLARGE, etc., modifiers.

www.EngineeringEBooksPdf.com

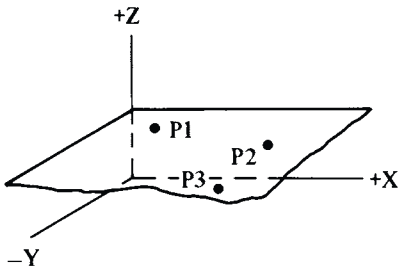
DS is used as the symbol for the Drive Surface; PS as the symbol for the Part Surface; and CS as the symbol for the Check Surface. The surfaces must be denoted in this sequence. The drive surface is the surface that the cutter will move along after coming in contact with the three surfaces. The two statements applicable to the two-surface start-up (Fig. 4b) are:

```
FROM/P1
GO/TO,DS,TO,PS
```

The one-surface start-up (Fig. 4c) is:

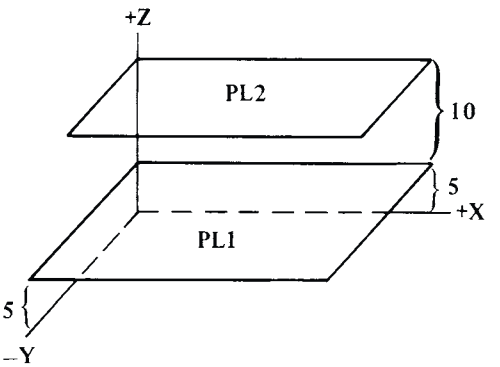
```
FROM/P1
GO/TO,DS
```

Planes



Planes are often used as the part surface, and are defined by three points not lying in a straight line

PL1 = PLANE/P1, P2, P3



A plane that is horizontal, or parallel to the *X-Y* plane, may be defined as:

PL1 = PLANE/0, 0, 1, 5 (0, 0, 1 does not change)

Alternatively, PL2 may be defined as a plane parallel to PL1

PL2 = PLANE/PARLEL, PL1, ZLARGE, 10

Cutter Movement Surfaces

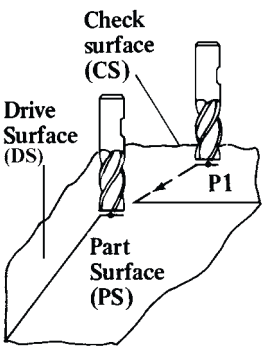


Fig. 4a.

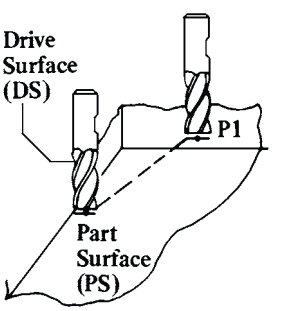

Fig. 4b.

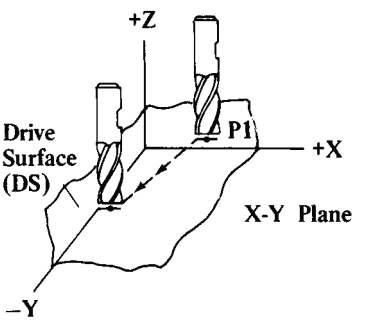

Fig. 4c.

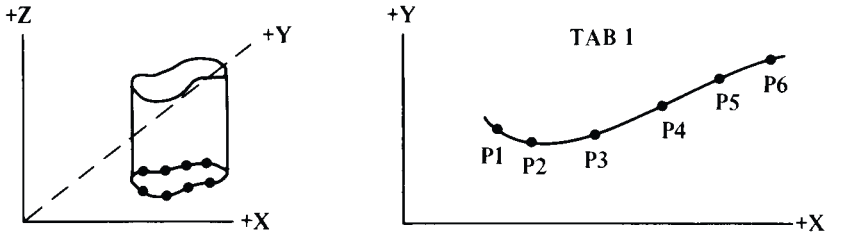
www.EngineeringEBooksPdf.com

Tabulated Cylinder



A tabulated cylinder is the line that is formed when an irregular cylinder intersects a plane. The plane intersected in the figure at the left is the X–Y plane.

A section of the line can be defined by a series of points on the line, as seen at the right. This line is called a TABCYL. The line must pass through all the points, therefore, it is best not to use too many. The statement to the computer would read:

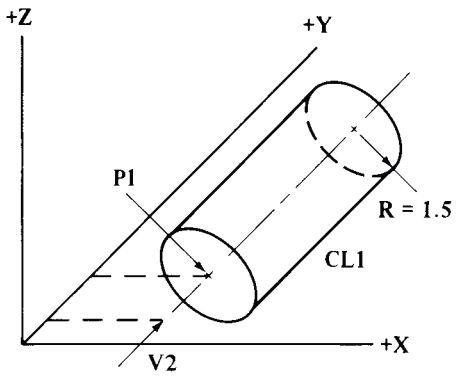
TAB1 = TABCYL/NOZ, SPLINE, P1, P2, P3, P4, P5, P6

or

TAB1 = TABCYL/NOZ, SPLINE, X., Y., X2, Y2, X3, Y3, X4, Y4, X5, Y5, X6, Y6
(where X and Y are the coordinates of the points)

3-D Geometry

Cylinder



Length of vector = 1

A cylinder is defined by a vector, a point on the centerline, and the radius

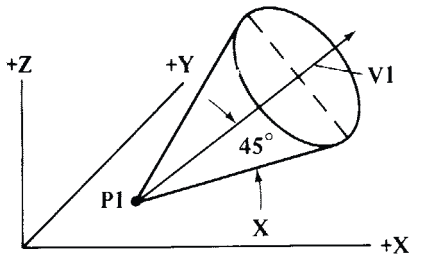
CL1 = CYLNDR/P1, V2, 1.5

where V2 is a unit vector in line with the cylinder centerline, and is described by the X, Y, and Z components. The cylinder centerline lies on the X–Y plane and is parallel to the Y-axis. The statement for the vector is therefore:

V2 = VECTOR/X component, Y component, Z component

V2 = VECTOR/0, 1, 0

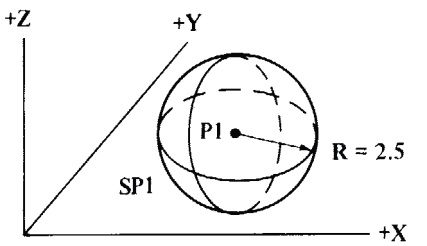
Cone



A cone is defined by its vertex, its axis as a unit vector, and the half angle (refer to cylinder for an example of a vector statement)

CON1 = CONE/P1,V1,45

Sphere



A sphere is defined by the center and the radius

SP1 = SPHERE/P1, RADIUS, 2.5

or

SP1 = SPHERE/5, 5, 3, 2.5 (where 5, 5, and 3 are the X, Y, and Z coordinates or P1, and 2.5 is the radius)

www.EngineeringEBooksPdf.com

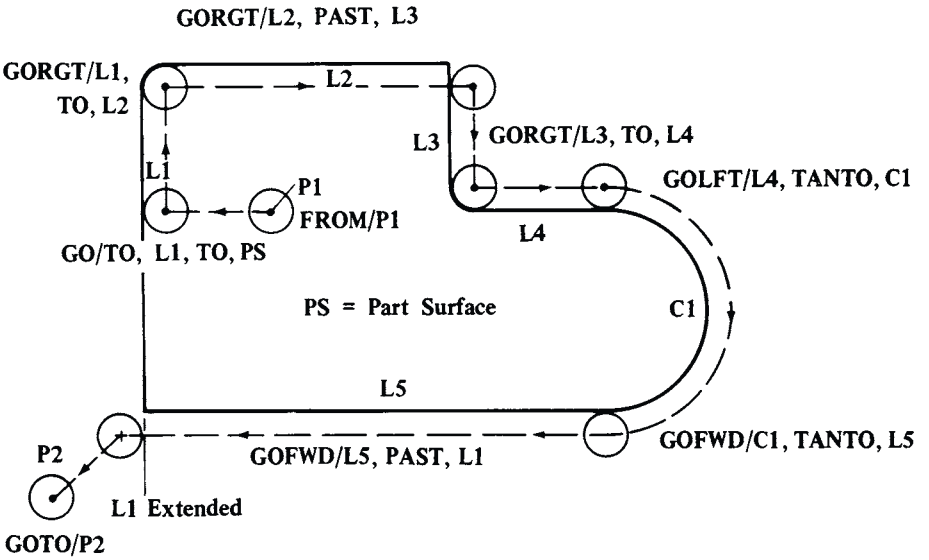


Fig. 5. A Completed Two-Surface Start-Up

Note that, in all three motion statements, the slash mark (/) lies between the GO and the TO. When the cutter is moving to a point rather than to surfaces, such as in a start-up, the statement is GOTO/ rather than GO/TO. A two-surface start-up, Fig. 3, when completed, might appear as shown in Fig. 5, which includes the motion statements needed. The motion statements, as they would appear in a part program, are shown at the left, below:

```
FROM/P1                    FROM/P1
GO/TO,L1,TO,PS             GOTO/P2
GORGT/L1,TO,L2             GOTO/P3
GORGT/L2,PAST,L3           GOTO/P4
GORGT/L3,TO,L4             GOTO/P5
GOLFT/L4,TANTO,C1          GOTO/P6
GOFWD/C1,TANTO,L5          GOTO/P7
GOFWD/L5,PAST,L1
GOTO/P2
```

GOTO statements can move the cutter throughout the range of the machine, as shown in Fig. 6. APT statements for such movements are shown at the right in the preceding example. The cutter may also be moved incrementally, as shown in Fig. 7. Here, the cutter is to move 2 inches in the + *X* direction, 1 inch in the + *Y* direction, and 1.5 inches in the + *Z* direction. The incremental move statement (indicated by DLTA) is:

```
GODLTA/2,1,1.5
```

The first position after the slash is the *X* movement; the second the *Y* movement, and the third, the *Z* movement.

Five-Axis Machining: Machining on five axes is achieved by causing the APT program to generate automatically a unit vector that is normal to the surface being machined, as shown in Fig. 8. The vector would be described by its *X*, *Y*, and *Z* components. These components, along with the *X*, *Y*, and *Z* coordinate positions of the tool tip, are fed into the postprocessor, which determines the locations and angles for the machine tool head and/or table.

APT Postprocessor Statements.—Statements that refer to the operation of the machine rather than to the geometry of the part or the motion of the cutter about the part are called postprocessor statements. APT postprocessor statements have been standardized internationally. Some common statements and an explanation of their meaning follow:

www.EngineeringEBooksPdf.com

MACHIN/ Specifies the postprocessor that is to be used. Every postprocessor has an identity code, and this code must follow the slash mark (/). For example: MACHIN/LATH,82

FEDRATE/ Denotes the feed rate. If in inches per minute (ipm), only the number

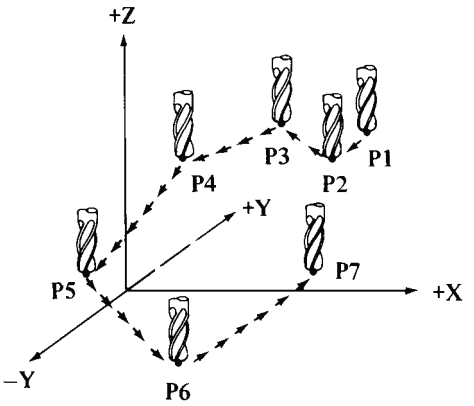

Fig. 6. A Series of GOTO Statements

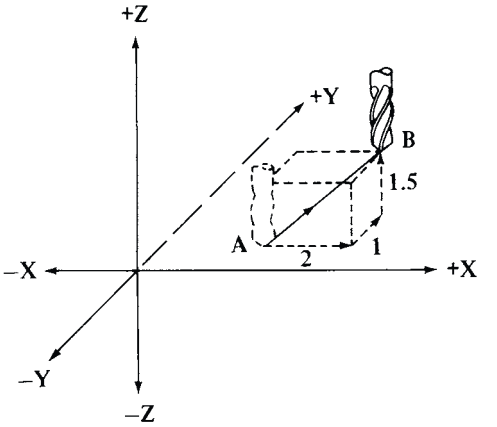

Fig. 7. Incremental Cutter Movements

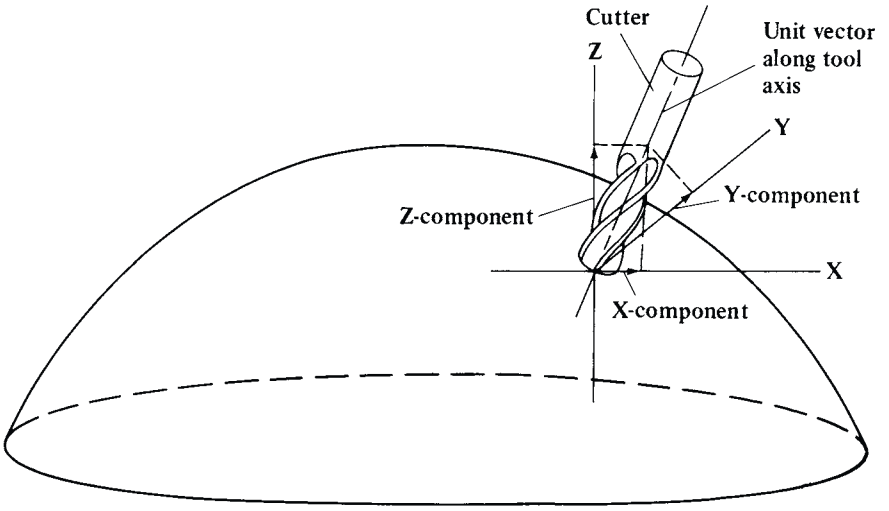

Fig. 8. Five-Axis Machining

need be shown. If in inches per revolution (ipr), IPR must be shown, for example: FEDRAT/.005,IPR

RAPID Means rapid traverse and applies only to the statement that immediately follows it

SPINDL/ Refers to spindle speed. If in revolutions per minute (rpm), only the number need be shown. If in surface feet per minute (sfm), the letters SFM need to be shown, for example: SPINDL/ 100SFM

COOLNT/ Means cutting fluid and can be subdivided into: COOLNT/ON, COOLNT/MIST, COOLNT/FLOOD, COOLNT/OFF

TURRET/ Used to call for a selected tool or turret position

CYCLE/ Specifies a cycle operation such as a drilling or boring cycle. An example of a drilling cycle is: CYCLE/DRILL,RAPTO,.45,FEDTO,0,IPR,.004. The next statement might be GOTO/PI and the drill will then move to P1 and perform the cycle operation. The cycle will repeat until the CYCLE/OFF statement is read

www.EngineeringEBooksPdf.com

END Stops the machine but does not turn off the control system

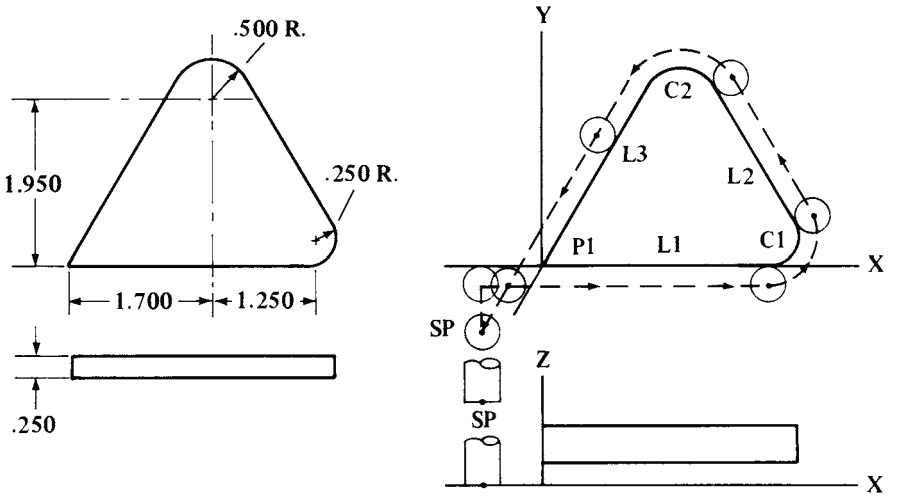

Fig. 9. Symbols for Geometrical Elements

APT Example Program.— A dimensioned drawing of a part and a drawing with the symbols for the geometry elements are shown in Fig. 9. A complete APT program for this part, starting with the statement PARTNO 47F36542 and ending with FINI, is shown at the left below.

The numbers at the left of the statements are for reference purposes only, and are not part of the program. The cutter is set initially at a point represented by the symbol SP, having coordinates $X = -0.5$, $Y = -0.5$, $Z = 0.75$, and moves to L1 (extended) with a one-surface start-up so that the bottom of the cutter rests on the X–Y plane. The cutter then moves counterclockwise around the part, past L1 (extended), and returns to SP. The coordinates of P1 are $X = 0$, $Y = 0$, and $Z = 1$.

Referring to the numbers at the left of the program:

(1) PARTNO must begin every program. Any identification can follow.

(2) The diameter of the cutter is specified. Here it is 0.25 inch.

(3) The feed rate is given as 5 inches per minute, which is contained in a postprocessor statement.

(4)-(10) Geometry statements.

(11)-(18) Motion statements.

(19) All APT programs end with FINI.

A computer printout from section II of the APT program is shown at the right, above. This program was run on a desktop personal computer. Lines (1) through (10) repeat the geometry statements from the original program. The motion statements are also repeated, and below each motion statement are shown the *X*, *Y*, and *Z* coordinates of the end points of the center-line (CL) movements for the cutter. Two lines of data follow those for the circular movements. For example, Line (18), which follows Line (17), GOFWD/C1,TANTO,L2, describes the *X* coordinate of the center of the arc, 2.9500, the *Y* coordinate of the center of the arc, 0.2500, and the radius of the arc required to be traversed by the cutter.

This radius is that of the arc shown on the part print, plus the radius of the cutter (0.2500 + 0.1250 = 0.3750). Line (18) also shows that the cutter is traveling in a counterclockwise (CCLW) motion. A circular motion is described in Lines (22), (23), and (24). Finally, the cutter is directed to return to the starting point, SP, and this command is noted in Line (27). The *X*, *Y*, and *Z* coordinates of SP are shown in Line (28).

APT for Turning.—In its basic form, APT is not a good program for turning. Although APT is probably the most suitable program for three-, four-, and five-axis machining, it is awkward for the simple two-axis geometry required for lathe operations. To overcome this problem, preprocessors have been developed especially for lathe part programming. The statements in the lathe program are automatically converted to basic APT statements in the computer and processed by the regular APT processor. An example of a lathe program, based on the APT processor and made available by the McDonnell Douglas Automation Co., is shown below. The numbers in parentheses are not part of the program, but are used only for reference. Fig. 10 shows the general set-up for the part, and Fig. 11 shows an enlarged view of the part profile with dimensions expressed along what would be the *X*- and *Y*-axes on the part print.

www.EngineeringEBooksPdf.com

Line (3) describes the tool. Here, the tool is located on face 1 of the turret and its tip is –1 inch "off" (offset) in the *X* direction and –6 inches "off" in the *Y* direction, when considering *X*–*Y* rather than *X*–*Z* axes. The cutting tool tip radius is also noted in this statement. Line (4) describes the dimensions of the rough material, or blank. Lines parallel to the *X*-axis are noted as FACE lines, and lines parallel to the *Z*-axis are noted as TURN lines. The FACE line (LN1) is located 3.5 inches along the *Z*-axis and parallel to the *X*-axis. The TURN line (LN2) is located 2 inches above the *Z*-axis and parallel to it. Note that in Figs. 10 and 11, the *X*-axis is shown in a vertical position and the *Z*-axis in a horizontal position. Line (5) describes the shape of the finished part. The term FILLET is used in this statement to describe a circle that is tangent to the line described by TURN, 1 and the line that is described by FACE, 1.5. The $ sign means that the statement is continued on the next line. These geometry elements must be contiguous and must be described in sequence. Line (6) specifies the position of the tool tip at the start of the operation, relative to the point of origin. Line (7) describes the roughing operation and notes that the material to be roughed out lies between BLANK1 and PART1; that the STEP, or depth of roughing cuts, is to be 0.1 inch; that 0.05 inch is to be left for the finish cut; that the speed is to be 300 sfm and the feed rate is to be 0.01 ipr; and that the tool to be used is identified by the symbol T1. Line (8) describes the finish cut, which is to be along the contour described by PART1.

CAD/CAM

CAD/CAM.—CAD in engineering means computer-aided design using a computer graphics system to develop mechanical, electrical/electronic, and architectural designs. A second D (CADD) is sometimes added (computer-aided drafting and design) and simply indicates a mechanical drafting or drawing program. CAD technology is the foundation for a wide variety of engineering, design, drafting, analysis, and manufacturing activities. Often a set of drawings initially developed in the design phase of a project is also used for analyzing and optimizing the design, creating mechanical drawings of parts and assemblies and for generating NC/CNC part programs that control machining operations. Formerly, after a component had been designed with CAD, the design was passed to a part programmer who developed a program for machining the components, either manually or directly on the computer (graphic) screen, but the process often required redefining and reentering part geometry. This procedure is often regarded as the CAM part of CAD/CAM, although CAM (for computer-aided manufacturing) has a much broader meaning and involves the computer in many other manufacturing activities such as factory simulation and planning analyses. Improvements in the speed and capability of computers, operating systems, and programs (including, but not limited to CAD) have simplified the process of integrating the manufacturing process and passing drawings (revised, modified, and translated, as necessary) through the design, analysis, simulation, and manufacturing stages.

A CAD drawing is a graphic representation of part geometry data stored in a drawing database file. The drawing database generally contains the complete list of entity (line, arc, etc.) and coordinate information required to build the CAD drawing, and additional information that may be required to define solid surfaces and other model characteristics. The format of data in a drawing file depends on the CAD program used to create the file. Generally, drawings are not directly interchangeable between drawing programs, however, drawings created in one system can usually be translated into an intermediate format or file type, such as DXF, that allows some of the drawing information to be exchanged between different programs. Translation frequently results in some loss of detail or loss of other drawing information because the various drawing programs do not all have the same features. The section Drawing Exchange Standards covers some of the available methods of transferring drawing data between different CAD programs.

www.EngineeringEBooksPdf.com

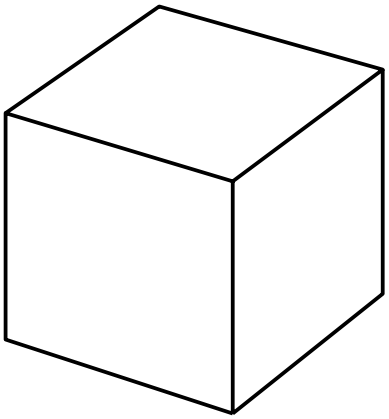

Fig. 1. Simple Wireframe Cube with Hidden Lines Automatically Removed

The simplest CAD drawings are two-dimensional and conform to normal engineering drafting practice showing orthographic (front, top, and side views, for example), exploded, isometric, or other views of a component. Depending on the complexity of the part and machining requirements, two-dimensional drawings are often sufficient for use in developing NC/CNC part programs. If a part can be programmed within a two-dimensional CAD framework, a significant cost saving may be realized because 3-D drawings require considerably more time, drawing skill, and experience to produce than 2-D drawings.

Wireframes are the simplest two- and three-dimensional forms of drawing images and are created by defining all edges of a part and, where required, lines defining surfaces. Wireframe drawing elements consist primarily of lines and arcs that can be used in practically any combination. A wireframe drawing of a cube, as in Fig. 1, consists of 12 lines of equal length (some are hidden and thus not shown), each perpendicular to the others. Information about the interior of the cube and the character of the surfaces is not included in the drawing. With such a system, if a 1-inch cube is drawn and a 0.5-inch cylinder is required to intersect the cube's surface at the center of one of its faces, the intersection points cannot be determined because nothing is known about the area between the edges. A wireframe model of this type is ambiguous if the edges overlap or do not meet where they should. Hidden-line removal can be used to indicate the relative elevations of the drawing elements, but normally a drawing cannot be edited when hidden lines have been removed. Hidden lines can be shown dashed or can be omitted from the view.

Two-dimensional drawing elements, such as lines, arcs, and circles, are constructed by directly or indirectly specifying point coordinates, usually x and y, that identify the location, size, and orientation of the entities. Three-dimensional drawings are also made up of a collection of lines, arcs, circles, and other drawing elements and are stored in a similar manner. A third point coordinate, z, indicates the elevation of a point in 3-D drawings. On the drawing screen, working in the x-y plane, the elevation is commonly thought of as the distance of a point or object into the screen (away from the observer) or out of the viewing screen (toward the observer). Coordinate axes are oriented according to the right-hand rule: If the fingers of the right hand point in the direction from the positive x-axis to the positive y-axis, the thumb of the right hand points in the direction of the positive z-axis.

Assigning a thickness (or extruding) to objects drawn in two dimensions quickly gives some 3-D characteristics to an object and can be used to create simple prismatic 3-D shapes, such as cubes and cylinders. Usually, the greatest difficulty in creating 3-D drawings is in picking and visualizing the three-dimensional points in a two-dimensional workspace (the computer display screen). To assist in the selection of 3-D points, many CAD programs use a split or windowed screen drawing area that can simultaneously show different views of a drawing. Changes made in the current or active window are reflected in each of the other windows. A typical window setup might show three orthogonal (mutually

www.EngineeringEBooksPdf.com

perpendicular) views of the drawing and a perspective or 3-D view. Usually, the views shown can be changed as required to suit the needs of the operator.

If carefully constructed, wireframe images may contain enough information to completely define the external geometry of simple plane figures. Wireframe images are especially useful for visualization of 3-D objects and are effectively used during the design process to check fits, clearances, and dimensional accuracy. Parts designed to be used together can be checked for accuracy of fit by bringing them together in a drawing, superimposing the images, and graphically measuring clearances. If the parts have been designed or drawn incorrectly, the errors will frequently be obvious and appropriate corrections can be made.

A more complicated level of 3-D drawing involves solids, with sections of the part being depicted on the screen as solid geometrical structures called primitives, such as cylinders, spheres, and cubes. Primitives can be assembled on a drawing to show more complex parts. Three distinct forms of image may be generated by 3-D systems, although not all systems make use of all three.

Surface Images: A surface image defines not only the edges of the part, but also the "skin" of each face or surface. For the example mentioned previously, the intersection for the 0.5-inch cylinder would be calculated and drawn in position. Surface models are necessary for designing free-form objects such as automotive body panels and plastics injection moldings used in consumer goods. For a surface model, the computer must be provided with much more information about the part in addition to the *x*, *y*, *z* coordinates defining each point, as in a wireframe. This information may include tangent vectors, surface normals, and weighting that determines how much influence one point has on another, twists, and other mathematical data that define abstract curves, for instance. Fig. 2 shows a typical 3-D surface patch.

Shaded images may be constructed using simulated light sources, reflections, colors, and textures to make renderings more lifelike. Surface images are sometimes ambiguous, with surfaces that overlap or miss each other entirely. Information about the interior of the part, such as the center of gravity or the volume, also may not be available, depending on the CAD package.

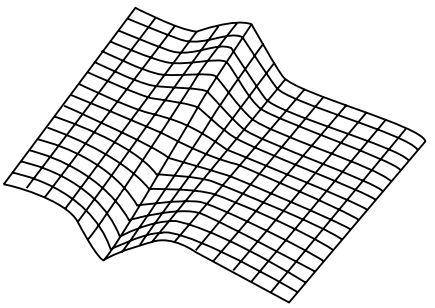

Fig. 2. A 3-D Surface Patch

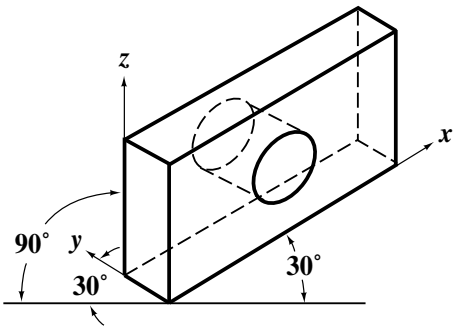

Fig. 3. Isometric Drawing Showing Orientation of Principle Drawing Axes

Solid Images: A solid image is the ultimate electronic representation of a part, containing all the necessary information about edges, surfaces, and the interior. Most solid-imaging programs can calculate volume, center of mass, centroid, and moment of inertia. Several methods are available for building a solid model. One method is to perform Boolean operations on simple shapes such as cylinders, cones, cubes, and blocks. Boolean operations are used to union (join), difference (subtract one from another), and intersect (find the common volume between two objects). Thus, making a hole in a part requires subtracting a cylinder from a rectangular block. This type of program is called constructive solid geometry (CSG).

www.EngineeringEBooksPdf.com

The boundary representation type of imaging program uses profiles of 2-D shapes that it extrudes, rotates, and otherwise translates in 3-D space to create the required solid. Sometimes combinations of the above two programs are used to attain a blend of flexibility, accuracy, and performance. For more precision, greatly increased time is needed for calculations, so compromises sometimes are needed to maintain reasonable productivity. Solid images may be sliced or sectioned on the screen to provide a view of the interior. This type of image is also useful for checking fit and assembly of one part with another.

Solid images provide complete, unambiguous representation of a part, but the programs require large amounts of computer memory. Each time a Boolean operation is performed, the list of calculations that must be done to define the model becomes longer, so that computation time increases.

Drawing Projections.—Several different techniques are used to display objects on paper or a computer screen to give an accurate three-dimensional appearance. Several of these methods are commonly used in CAD drawings.

Isometric drawings, as in Fig. 3, can be used to good effect for visualizing a part because they give the impression of a 3-D view and are often much faster to create. Isometric drawings are created in 2-D space, with the *x*- and *y*-axes being inclined at 30 degrees to the horizontal, as shown in Fig. 3, and the *z*-axis as vertical. Holes and cylinders in isometric drawings become elliptical. Because of the orientation of the *x*-, *y*-, and *z*-axes, the true length of lines may not be accurately represented in isometric drawings and dimensions should not be taken directly from a print. Some CAD programs have a special set of predefined drawing axes to facilitate creating isometric drawings.

In *parallel projections,* lines that are parallel in an object, assembly, or part being portrayed remain parallel in the drawing. Parallel projections show 3-D objects in a dimensionally correct manner, so that relative and scaled dimensions may be taken directly from a drawing. However, drawings may not appear as realistic as isometric or perspective drawings.

A characteristic of *perspective drawings* is that parallel lines converge (see Fig. 4) so that objects that are farther away from the observer appear smaller. Perspective drawing techniques are used in some three-dimensional drawings to convey the true look of an object, or group of objects. Because objects in perspective drawings are not drawn to scale, dimensional information cannot be extracted from the drawings of a part. Some 3-D drawing packages have a true perspective drawing capability, and others use a simulation technique to portray a 3-D perspective.

An *axonometric projection* is a 3-D perpendicular projection of an object onto a surface, such that the object is tilted relative to its normal orientation. An axonometric projection of a cube, as in Fig. 1, shows three faces of the cube. CAD systems are adept at using this type of view, making it easy to see an object from any angle.

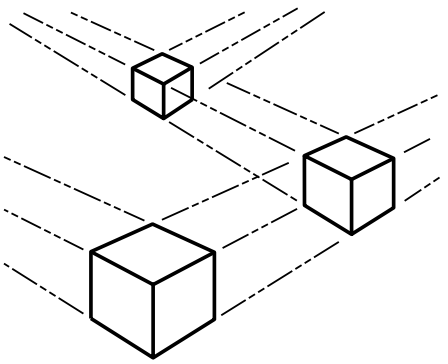

Fig. 4. Perspective Drawing of Three Equal-Size Cubes and Construction Lines

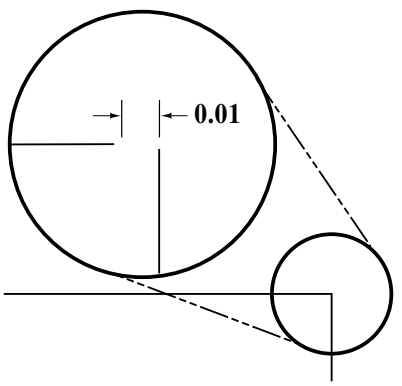

Fig. 5. A Common Positioning Error

www.EngineeringEBooksPdf.com

Drawing Tips and Traps.—Images sometimes appear correct on the screen but contain errors that show up when the drawing is printed or used to produce NC/CNC part programs. In Fig. 5, the two lines within the smaller circle appear to intersect at a corner, but when the view of the intersection is magnified, as in the larger circle, it is clear that the lines actually do not touch. Although an error of this type may not be easily visible, other parts placed in the drawing relative to this part will be out of position.

A common problem that shows up in plotting, but is difficult to detect on the screen, comes from placing lines in the same spot. When two or more lines occupy exactly the same location on the screen, there is usually no noticeable effect on the display. However, when the drawing is plotted, each line is plotted separately, causing the single line visible to become thicker and darker. Likewise, if a line that appears continuous on the screen is actually made up of several segments, plotting the line will frequently result in a broken, marred, or blotted appearance to the line because the individual segments are plotted separately, and at different times. To avoid these problems and to get cleaner looking plots, replace segmented lines with single lines and avoid constructions that place one line directly on top of another.

Exact decimal values should be used when entering point coordinates from the keyboard, if possible; fractional sizes should be entered as fractions, not truncated decimals. For example, $\frac{5}{16}$ should be entered as 0.3125 or $\frac{5}{16}$, not 0.313. Accumulated rounding errors and surprises later on when parts do not fit are thus reduced. Drawing dimensions, on the other hand, should not have more significant digits or be more precise than necessary. Unnecessary precision in dimensioning leads to increased difficulty in the production stage because the part has to be made according to the accuracy indicated on the drawing.

Snap and *object snap* commands make selecting lines, arcs, circles, or other drawing entities faster, easier, and more accurate when picking and placing objects on the screen. Snap permits only points that are even multiples of the snap increment to be selected by the pointer. A $\frac{1}{8}$-inch snap setting, for example, will allow points to be picked at exactly $\frac{1}{8}$-inch intervals. Set the *snap increment* to the smallest distance increment (1 in., $\frac{1}{4}$ in., 1 ft., etc.) being used in the area of the drawing under construction and reset the snap increment frequently, if necessary. The snap feature can be turned off during a command to override the setting or to select points at a smaller interval than the snap increment allows. Some systems permit setting a different snap value for each coordinate axis.

The *object snap* selection mode is designed to select points on a drawing entity according to predefined characteristics of the entity. For example, if end-point snap is in effect, picking a point anywhere along a line will select the end point of the line nearest the point picked. Object snap modes include point, intersection, midpoint, center and quadrants of circles, tangency point (allows picking a point on an arc or circle that creates a tangent to a line), and perpendicular point (picks a point that makes a perpendicular from the base point to the object selected). When two or more object snap modes are used together, the nearest point that meets the selection criteria will be chosen. Using object snap will greatly reduce the frequency of the type of problem shown in Fig. 5.

Copy: Once drawn, avoid redrawing the same object. It is almost always faster to copy and modify a drawing than to draw it again. The basic copy commands are: copy, array, offset, and mirror. Use these, along with move and rotate and the basic editing commands, to modify existing objects. Copy and move should be the most frequently used commands. If possible, create just one instance of a drawing object and then copy and move it to create others.

To create multiple copies of an object, use the *copy, multiple* feature to copy selected objects as many times as required simply by indicating the destination points. The *array* command makes multiple copies of an object according to a regular pattern. The rectangular array produces rows and columns, and the polar array puts the objects into a circular pattern, such as in a bolt circle. *Offset* copies an entity and places the new entity a specified

www.EngineeringEBooksPdf.com

distance from the original and is particularly effective at placing parallel lines and curves, and for creating concentric copies of closed shapes. *Mirror* creates a mirror image copy of an object, and is useful for making right- and left-hand variations of an object as well as for copying objects from one side of an assembly to the other. In some CAD programs, a system variable controls whether text is mirrored along with other objects.

Many manufacturers distribute drawings of their product lines in libraries of CAD drawings, usually as DXF files, that can be incorporated into existing drawings. The suitability of such drawings depends on the CAD program and drawing format being used, the skill of the technician who created the drawings, and the accuracy of the drawings. A typical example, Fig. 6, shows a magnetically coupled actuator drawing distributed by Tol-O-Matic, Inc. Libraries of frequently used drawing symbols and blocks are also available from commercial sources.

Create Blocks of Frequently Used Objects: Once created, complete drawings or parts of drawings can be saved and later recalled, as needed, into another drawing. Such objects can be scaled, copied, stretched, mirrored, rotated, or otherwise modified without changing the original. When shapes are initially drawn in unit size (i.e., fitting within a 1×1 square) and saved, they can be inserted into any drawing and scaled very easily. One or more individual drawing elements can be saved as a group element, or *block,* that can be manipulated in a drawing as a single element. Block properties vary, depending on the drawing program, but are among the most powerful features of CAD. Typically, blocks are uniquely named and, as with simple objects, may be saved in a file on the disk. Blocks are ideal for creating libraries of frequently used drawing symbols. Blocks can be copied, moved, scaled very easily, rotated, arrayed, and inserted as many times as is required in a drawing and manipulated as one object. When scaled, each object within the block is also scaled to the same degree.

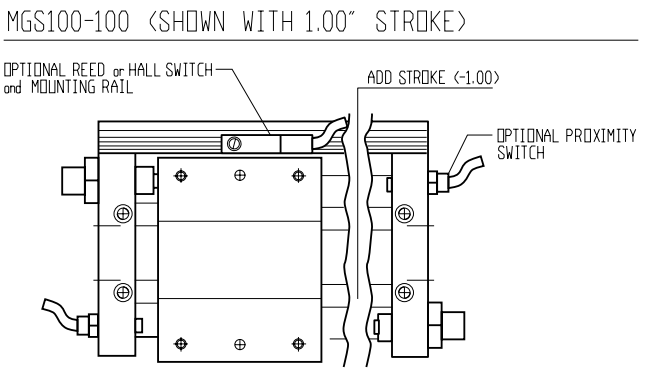

Fig. 6. Manufacturer's Drawing of a Magnetically Coupled Actuator (*Courtesy of Tol-O-Matic, Inc.*)

When a family of parts is to be drawn, create and block a single drawing of the part that fits within a unit cube of convenient size, such as $1 \times 1 \times 1$. When the block is inserted in a drawing, it is scaled appropriately in the *x*-, *y*-, and *z*-directions. For example, $\frac{3}{8}$-inch bolts can be drawn 1 inch long in the *x*-direction and $\frac{3}{8}$-inch in diameter in the *y*-*z* plane. If a 5-inch bolt is needed, insert the "bolt" block with a scale of 5 in the *x*-direction and a scale of 1 in the *y*- and *z*-directions.

Once blocked, the individual components of a block (lines, arcs, circles, surfaces, and text, for example) cannot be individually changed or edited. To edit a block, a copy (instance) of the block must be *exploded* (unblocked) to divide it into its original components. Once exploded, all the individual elements of the block (except other blocks) can be edited. When the required changes have been made, the block must be redefined (redeclared as a block by giving it a name and identifying its components). If the block is redefined using the same name, any previous references to the block in the drawing will be

www.EngineeringEBooksPdf.com

updated to match the redefined block. For example, an assembly drawing is needed that shows a mechanical frame with 24 similar control panels attached to it. Once one of the panels is drawn and defined as a block (using the name *PANEL*, for instance), the block can be inserted (or copied) into the drawing 24 times. Later, if changes need to be made to the panel design, one instance of the block *PANEL* can be exploded, modified, and redefined with the name *PANEL*. When *PANEL* is redefined, every other copy of the *PANEL* block in the drawing is also redefined, so every copy of *PANEL* in the drawing is updated. On the other hand, if the block was redefined with a different name, say, *PANEL1*, existing copies of *PANEL* remain unchanged. When redefining a block that already exists in the drawing, be sure to use the same insertion point that was used for the original definition of the block; otherwise, the positions of existing blocks with the same name will be changed.

Use of Text Attributes to Request Drawing Information Automatically: Text attributes are a useful method for attaching textual information to a particular part or feature of a drawing. An attribute is basically a text variable that has a name and can be assigned a value. Attributes are created by defining attribute characteristics such as a name, location in the drawing, text size and style, and default value. The attribute value is assigned when the attribute is inserted into a drawing as part of a block.

Fig. 7 shows two views of a title block for size A to C drawing sheets. The upper figure includes the title block dimensions (included only for reference) and the names and locations of the attributes (COMPANY, TITLE1, TITLE2, etc.). When a block containing text attributes is inserted in a drawing, the operator is asked to enter the value of each attribute. To create this title block, first draw the frame of the title block and define the attributes (name, location and default value for: company name and address, drawing titles [2 lines], drawing size, drawing number, revision number, scale, and sheet number). Finally, create and name a block containing the title frame and all the attribute definitions (do not include the dimensions).

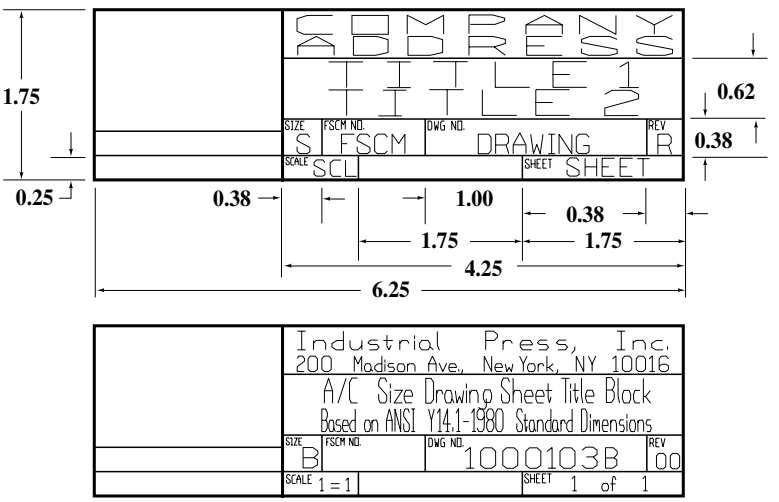

Fig. 7. Title Block for A to C Size Drawing Sheets Showing the Placement of Text Attributes. The Lower Figure Shows the Completed Block

When the block is inserted into a drawing, the operator is asked to enter the attribute values (such as company name, drawing title, etc.), which are placed into the title block at the predetermined location. The lower part of Fig. 7 shows a completed title block as it might appear inserted in a drawing. A complete drawing sheet could include several additional blocks, such as a sheet frame, a revision block, a parts list block, and any other supplementary blocks needed. Some of these blocks, such as the sheet frame, title, and parts list blocks, might be combined into a single block that could be inserted into a drawing at one time.

www.EngineeringEBooksPdf.com

Define a Default Drawing Configuration: Drawing features that are commonly used in a particular type of drawing can be set up in a template file so that frequently used settings, such as text and dimension styles, text size, drawing limits, initial view, and other default settings, are automatically set up when a new drawing is started. Different configurations can be defined for each frequently used drawing type, such as assembly, parts, or printed circuit drawings. When creating a new drawing, use one of the template files as a pattern or open a template file and use it to create the new drawing, saving it with a new name.

Scaling Drawings: Normally, for fast and accurate drawing, it is easiest to draw most objects full scale, or with a 1:1 scale. This procedure greatly simplifies creation of the initial drawing, and ensures accuracy, because scale factors do not need to be calculated. If it becomes necessary to fit a large drawing onto a small drawing sheet (for example, to fit a 15×30 inch assembly onto a 11×17 inch, B-sized, drawing sheet), the drawing sheet can be scaled larger to fit the assembly size. Likewise, large drawing sheets can be scaled down to fit small drawings. The technique takes some practice, but it permits the drawing assembly to be treated full scale. If editing is required at a later date (to move something or add a hole in a particular location, for example), changes can be made without rescaling and dimensions can be taken directly from the unscaled drawing on the computer.

Scaling Text on Drawing Sheets: It is usually desirable that text, dimensions, and a few other features on drawings stay a consistent size on each sheet, even when the drawing size is very different. The following procedure ensures that text and dimensions (other features as well, if desired) will be the same size, from drawing to drawing without resorting to scaling the drawing to fit onto the drawing sheet.

Create a drawing sheet having the exact dimensions of the actual sheet to be output (A, B, C, D, or E size, for example). Use text attributes, such as the title block illustrated in Fig. 7, to include any text that needs to be entered each time the drawing sheet is used. Create a block of the drawing sheet, including the text attributes, and save the block to disk. Repeat for each size drawing sheet required.

Establish the nominal text and dimension size requirements for the drawing sheet when it is plotted full size (1:1 scale). This is the size text that will appear on a completed drawing. Use Table 1 as a guide to recommended text sizes of various drawing features.

Table 1. Standard Sizes of Mechanical Drawing Lettering *ANSI Y14.2M-1992*

Use For	Inch		Metric	
	Min. Letter Heights, (in)	Drawing Size	Min. Letter Heights, (mm)	Drawing Size
Drawing title, drawing size, CAGE Code, drawing number, and revision letter[a]	0.24	D, E, F, H, J, K	6	A0, A1
	0.12	A, B, C, G	3	A2, A3, A4
Section and view letters	0.24	All	6	All
Zone letters and numerals in borders	0.24	All	6	All
Drawing block headings	0.10	All	2.5	All
All other characters	0.12	All	3	All

[a] When used within the title block.

Test the sheet by setting the text size and dimension scale variables to their nominal values (established above) and place some text and dimensions onto the drawing sheet. Plot a copy of the drawing sheet and check that text and dimensions are the expected size.

To use the drawing sheet, open a drawing to be placed on the sheet and insert the sheet block into the drawing. Scale and move the sheet block to locate the sheet relative to the drawing contents. When scaling the sheet, try to use whole-number scale factors (3:1, 4:1, etc.), if possible; this will make setting text size and dimension scale easier later on. Set the text-size variable equal to the nominal text size multiplied by the drawing sheet insertion scale (for example, for 0.24 text height on a drawing sheet scaled 3:1, the text-size variable will be set to $3 \times 0.24 = 0.72$). Likewise, set the dimension-scale variable equal to the nominal dimension size multiplied by the drawing sheet insertion scale.

www.EngineeringEBooksPdf.com

Once the text size and dimensions scale variables have been set, enter all the text and dimensions into the drawing. If text of another size is needed, multiply the *new* nominal text size by the sheet scale to get the actual size of the text to use in the drawing.

Use Appropriate Detail: Excessive detail may reduce the effectiveness of the drawing, increase the drawing time on individual commands and the overall time spent on a drawing, and reduce performance and speed of the CAD program. Whenever possible, symbolic drawing elements should be used to represent more complicated parts of a drawing unless the appearance of that particular component is essential to the drawing.

Drawing everything to scale often serves no purpose but to complicate a drawing and increase drawing time. The importance of detail depends on the purpose of a drawing, but detail in one drawing is unnecessary in another. For example, the slot size of a screw head (length and width) varies with almost every size of screw. If the purpose of a drawing is to show the type and location of the hardware, a symbolic representation of a screw is usually all that is required. The same is generally true of other screw heads, bolt threads, bolt head diameters and width across the flats, wire diameters, and many other hardware features.

Drawing Exchange Standards.—The ability to transfer working data between different CAD, CAD/CAM, design analysis, and NC/CNC programs is one of the most important requirements of engineering drawing programs. Once an engineer, designer, draftsman, or machinist enters relevant product data into his or her machine (computer or machine tool), the information defining the characteristics of the product should be available to the others involved in the project without recreating or reentering it. In view of manufacturing goals of reducing lead time and increasing productivity, concurrent engineering, and improved product performance, interchangeable data are a critical component in a CAD/CAM program. Depending on the requirements of a project, it may be entirely possible to transfer most if not all of the necessary product drawings from one drawing system to another.

IGES stands for Initial Graphics Exchange Specification and is a means of exchanging or converting drawings and CAD files for use in a different computer graphics system. The concept is shown diagrammatically in Fig. 8. Normally, a drawing prepared on the computer graphics system supplied by company A would have to be redrawn before it would operate on the computer graphics system supplied by company B. However, with IGES, the drawing can be passed through a software package called a preprocessor that converts it into a standardized IGES format that can be stored on a magnetic disk. A postprocessor at company B is then used to convert the standard IGES format to that required for their graphics system. Both firms would be responsible for purchasing or developing their own preprocessors and postprocessors, to suit their own machines and control systems. Almost all the major graphics systems manufacturing companies today either have or are developing IGES preprocessor and postprocessor programs to convert software from one system to another.

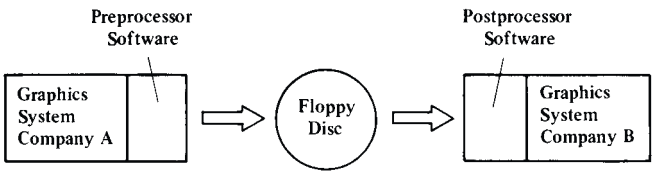

Fig. 8.

DXF stands for Drawing Exchange Format and is a pseudo-standard file format used for exchanging drawings and associated information between different CAD and design analysis programs. Nearly all two- and three-dimensional CAD programs support some sort of drawing exchange through the use of DXF files, and most can read and export DXF files. There are, however, differences in the drawing features supported and the manner in which the DXF files are handled by each program. For example, if a 3-D drawing is exported in the DXF format and imported into a 2-D CAD program, some loss of information results

www.EngineeringEBooksPdf.com

because all the 3-D features are not supported by the 2-D program, so that most attempts to make a transfer between such programs fail completely. Most common drawing entities (lines, arcs, etc.) will transfer successfully, although other problems may occur. For example, drawing entities that are treated as a single object in an original drawing (such as blocks, hatch patterns, and symbols) may be divided into hundreds of individual components when converted into a DXF file. Consequently, such a drawing may become much more difficult to edit after it is transferred to another drawing program.

ASCII stands for American Standard Code for Information Interchange. ASCII is a code system that describes the manner in which character-based information is stored in a computer system. Files stored in the ASCII format can be transferred easily between computers, even those using different operating systems. Although ASCII is not a drawing file format, many CAD drawing formats (DXF and IGES, for example) are ASCII files. In these files, the drawing information is stored according to a specific format using ASCII characters. ASCII files are often referred to as pure text files because they can be read and edited by simple text editors.

HPGL, for Hewlett-Packard Graphics Language, is a format that was first developed for sending vector- (line-) based drawing information to pen plotters. The format is commonly used for sending drawing files to printers and plotters for printing. Because HPGL is a character-based format (ASCII), it can be transferred between computers easily. Normally, devices that recognize the HPGL format can print the files without using the program on which the file (a drawing, for example) was created.

STL is a CAD drawing format that is primarily used to send CAD drawings to *rapid automated prototyping* machines. STL is a mnemonic abbreviation for stereo-lithography, the technique that is used to create three-dimensional solid models directly from computer-generated drawings and for which the drawing format was originally developed. Most prototyping machines use 3-D CAD drawing files in STL format to create a solid model of the part represented by a drawing.

STEP stands for Standard for Exchange of Product Model Data and is a series of existing and proposed ISO standards written to allow access to all the data that surround a product. It extends the IGES idea of providing a geometric data transfer to include all the other data that would need to be communicated about a product over its lifetime, and facilitates the use and accessibility of the product data. Although STEP is a new standard, software tools have been developed for converting data from the IGES to STEP format and from STEP to IGES.

Rapid Automated Prototyping.—Rapid automated prototyping is a method of quickly creating an accurate three-dimensional physical model directly from a computerized conception of the part. The process is accomplished without machining or the removal of any material, but rather is a method of building up the model in three-dimensional space. The process makes it possible to easily and automatically create shapes that would be difficult or impossible to produce by any other method. Currently, production methods are able to produce models with an accuracy tolerance of ± 0.005 inch. Models are typically constructed of photoreactive polymer resins, nylon, polycarbonate or other thermoplastics, and investment casting wax. The model size is limited by the capability of the modeling machines to about 1 cubic foot at the present, however, large models can be built in sections and glued or otherwise fastened together.

Much of the work and a large part of the cost associated with creating a physical model by rapid prototyping are in the initial creation of the CAD model. The model needs to be a 3-D design model, built using wireframe, surface, or solid CAD modeling techniques. Many full-featured CAD systems support translation of drawing files into the STL format, which is the preferred file format for downloading CAD models to rapid prototyping machines. CAD programs without STL file format capability can use the IGES or DXF file format. This process can be time-consuming and expensive because additional steps may have to

www.EngineeringEBooksPdf.com

be taken by the service bureau to recreate features lost in converting the IGES or DXF file into STL format. If the design file has to be edited by a service bureau to recreate surfaces lost in the translation, unwanted changes to the model may occur, unnoticed. The safest route is to create a CAD model and export it directly into the STL format, leaving little chance for unexpected errors. Reverse STL generators are also available that will display a file saved in STL format or convert it into a form that can be imported into a CAD program.

DNC.—DNC stands for Direct Numerical Control and refers to a method of controlling numerical control machines from a remote location by means of a link to a computer or computer network. In its simplest form, DNC consists of one NC or CNC machine linked by its serial port to a computer. The computer may be used to develop and store CNC part programs and to transfer part programs to the machine as required. DNC links are normally two-directional, meaning that the NC/CNC can be operated from a computer terminal and the computer can be operated or ordered to supply data to the NC/CNC from the machine's control panel.

The number of machines that can be connected to a DNC network depends on the network's capability; in theory, any number of machines can be attached, and controlled. The type of network depends on the individual DNC system, but most industry standard network protocols are supported, so DNC nodes can be connected to existing networks very easily. Individual NC/CNC machines on a network can be controlled locally, from a network terminal in another building, or even from a remote location miles away through phone or leased lines.

www.EngineeringEBooksPdf.com

MANUFACTURING PROCESS

Principles of Iron and Steel Manufacture

Steel is the most useful of known metals. Its major constituent is iron which is combined with carbon, and often also with various alloying elements. Metallic iron in its pure form is not available in the crust of the earth; it is found only in iron-bearing materials, designated as iron ores.

Iron Ores.— About five per cent of the earth's crust is composed of iron, which is almost always found in chemical combination with oxygen, sulphur, silicon and other chemical elements. In order to be commercially usable the iron ore must contain a sufficient proportion of iron. In the past, only iron ores with a relatively high, about 50 to 70 per cent, iron content were used, but the gradual exhaustion of known deposits of richer ores has made the use of ores with lower iron content, in the order of 20 to 40 per cent, necessary. Ores with poorer iron content must first be treated to eliminate the excess rock material, using processes known as *beneficiation.* These consist of crushing the ores, reducing them to a fine powder from which the non-iron-bearing constituents can be removed. The remaining rich iron-bearing mineral powder is then mixed with powdered coal to form pellets which can be baked (sintered) for obtaining the increased strength needed for handling.

The Making of Iron.— Blast furnaces are used for extracting the iron from the ores. These are high, cylindrical structures which are loaded with alternate layers of coke, iron and lime. The burning of the coke is supported by a continuous blast of heated air blown into the furnace in large quantities. The high heat causes the iron content of the ore to melt, while the carbon monoxide gas generated by the combustion of the coke reduces the oxides of iron. The limestone functions as a flux, converting into an easily removable slag many of those elements of the ore which would constitute undesirable impurities in the iron. The blast furnace is kept in continuous operation, new charges of coke, iron ore and flux being introduced periodically, while at intervals, the formed slag and the molten, greatly deoxidized iron are removed.

Most of the iron produced in blast furnaces is used in the molten state in steel making furnaces. In this country, only about five per cent of the output is used in solid form, known as pigs, hence the blast furnace product is called pig iron, a general designation regardless of its state.

The Making of Steel.— The pig iron produced by the blast furnace process contains a high amount of carbon, a part of which must be removed for obtaining steel with a closely controlled carbon content, usually in the order of less than one per cent. There are several methods for achieving that goal, but most of the steel produced presently originates from one of the following three general processes.

1) *The Basic Open Hearth Process:* The name originates from the general shape of the furnaces, which are installed in rows of several units, operated concurrently but with staggered charging periods, all being serviced from a common charging floor. The furnaces operate by combining two systems, the *reverbatory,* in which part of the heating effect is accomplished by radiation from the heated roof, and the *regenerative,* utilizing the hot gases from the combustion of the fuel for heating either of two brick lined chambers, which are then used alternately for preheating the cold incoming air before conducting it into the furnace.

The charge used in open hearth furnaces may consist of a) steel scrap and liquid pig iron; b) steel scrap and solid pig iron; and c) all steel scrap, depending on the availability and the relative cost of the different charge materials.

After the meltdown and the different phases of the working period, a cycle requiring usually about ten hours unless accelerated by the use of oxygen, the hot steel is tapped into ladles, the content of which is poured into ingot molds. This is called teeming.

www.EngineeringEBooksPdf.com

2) *The Basic Oxygen Process:* The furnaces are tiltable converted vessels of large size holding about 300 tons of charge material which consists mainly of liquid pig iron. Often scrap is also added, the maximum proportion (about 30 per cent) of which, however, is less than that admissible for open hearth furnaces. After the charge has been loaded, a tube with a special nozzle, called a lance, is introduced, through which a jet of high purity oxygen is blown at supersonic speed onto the charge. This causes a vehement reaction of the charge, converting it within a short time (about 30 minutes) into steel of the desired carbon content. When the process is finished, the oxygen flow is shut off, the lance retracted and the converter tilted into a position where the molten metal can be poured into the ladle. Alloying elements may be added to the content of the ladle prior to emptying the metal into ingot molds in a teeming process similar to that used in the open hearth method. The basic oxygen process, a relatively recent development, is much faster than the open hearth process and is preferred when sufficient amount of liquid pig iron is available. Currently about one-half of the steel manufactured in the United States is produced by the basic oxygen process.

3) *Air Melt Electric Furnace Processes:* Two different systems are used, based on the following types of equipment:

a) The basic electric-arc furnace, in which heat is produced through arcing action from electrodes to metal, the electrodes being lowered when the level of the metal sinks as its melting progresses. Since no oxygen is necessary to support combustion, the purity of the metal can be better controlled than in the previously discussed types of furnaces. Electric arc furnaces can accept charges consisting almost entirely of solid scrap.

b) The induction furnace, which is essentially a transformer, is surrounded by a coil in which high frequency current is circulating, with the metal acting as the core. Induction furnaces are mostly used for remelting processes, in the refinement and alloying of steel.

Vacuum Melting and Degassing Processes.—The purpose of degassing is to remove hydrogen, oxygen and nitrogen from the steel, because the presence of these elements affects the purity, and thereby the desirable mechanical properties of the metal. These processes are based on the principle that the solubility of a gas in the liquid steel decreases with a decreasing pressure of the surrounding atmosphere. Steel refinement by these processes is rapidly growing in acceptance as a means of producing purer steels of more consistently dependable quality.

Three basic systems are generally applied, each serving primarily a specific area of use:

1) *Vacuum degassing of large sections* such as ingots and heavy forgings, can be carried out by:

a) stream degassing, immediately preceding the pouring of the metal into the ingot mold, leading the metal through an intermediate ladle kept under vacuum;

b) ladle degassing, in which the ladle is placed in a steel tank, which then is evacuated;

c) vacuum lifter degassing, using a vacuum chamber suspended above a ladle and connected with it by a nozzle, utilizing atmospheric pressure to transfer the steel.

2) *Vacuum induction melting,* a process in use over 30 years, in which an ordinary induction furnace is placed inside a vacuum chamber, thereby producing the steel under close heat control and free from air contamination.

3) *Consumable electrode vacuum arc remelting,* using electrodes of predetermined composition, remelting them by electric arc in vacuum, into a water cooled copper crucible. It is a refining process for producing steel of very high purity.

Iron Ore.—Iron ore is an oxide of iron containing, ordinarily, from 35 to 65 per cent of iron, and, in addition, oxygen, phosphorus, sulphur, silica (sand) and other impurities. If the ore contains less than 40 per cent iron, it must first be concentrated, and if less than 25 per cent iron, it is not considered a commercial product, owing to the excessive cost of smelting. At the present time, the ores mined in this country average slightly over 50 per cent iron, although the “Lake” ores sometimes contain over 60 per cent.

www.EngineeringEBooksPdf.com

Pig Iron.—When iron ore is charged in a blast furnace, mixed with limestone as a flux, and melted down with either charcoal, coke or anthracite coal as fuel, the resulting metal is what is commercially known as pig iron. It contains about 93 per cent of pure iron, from 3 to 5 per cent of carbon, and some silicon, phosphorus, sulphur, etc. Pig iron is used in foundries for the manufacture of iron castings by simply re-melting it in a cupola and without materially changing its chemical composition.

Pig iron is classified: 1) according to the method of manufacture; 2) its intended use; and 3) its composition.

The methods of manufacture produce: 1) coke pig iron, which is smelted with coke and always with a hot blast; 2) charcoal pig, which is smelted with charcoal and either a hot or cold blast; and 3) anthracite pig, smelted with anthracite coal mixed with coke, using a hot blast.

Classifications according to intended use are: 1) Bessemer pig, used for the Bessemer and acid open-hearth processes of making steel; 2) basic pig, used for the basic process; 3) malleable pig, used for malleable cast-iron castings; 4) foundry pig, used for foundry work; and 5) forge pig, an inferior grade used for puddling and some classes of foundry work.

The grading according to composition was formerly done by breaking the pig and examining the fracture; the modern method is by chemical analysis. In this country pig iron is usually sold in tons of 2240 pounds.

Classes of Steel.—The word steel is applied to many mixtures which differ greatly from each other in their chemical as well as physical qualities. The ingredient that exerts the most influence on steel is carbon. High-grade razor steel contains about 1.25 per cent of carbon, spring steel 1 per cent, steel rails from 0.50 to 0.75 per cent, and soft steel boiler plate may have as little as 0.062 per cent of carbon. Steel which is very low in carbon can easily be welded, but it cannot be hardened; when the carbon is above 0.33 per cent, welding is more difficult and can be done only by the use of borax or some other flux, or by the electric or thermit processes. Steel with carbon above 0.75 per cent can readily be hardened. In tool steel, other ingredients than carbon are sometimes used to influence its hardness, such as nickel, manganese, chromium, tungsten, etc., the last named playing an important part in so-called "high-speed steels," that is, tool steels that will cut metal at a high speed without losing their temper or hardness. Pig iron and cast iron contain about 4 per cent of carbon, and wrought iron only a trace of it, while steel is between these two extremes; hence, in the manufacture of steel it is important to get the right proportion of carbon. One method is to burn the carbon out of pig iron, as in the Bessemer and open-hearth processes, and the other method is to add carbon to wrought iron, as in the crucible process.

Puddling Process.—In the manufacture of wrought iron, pig iron is melted in a puddling furnace where most of the silicon, carbon, phosphorus, and other impurities are separated from the iron, forming the puddle cinder. Pig iron melts at about 2100 degrees F., steel at about 2500 degrees, and wrought iron at about 2800 degrees. The temperature in the puddling furnace is high enough to melt pig iron, but not high enough to keep wrought iron in a liquid state; therefore, as soon as the small particles of iron become purified, they partly congeal ("come to nature") forming a spongy mass in which small globules of iron are in a semi-plastic state. This mass is divided by the puddler into "puddle balls" or lumps of about 200 pounds each. These lumps are formed into elongated blooms in a rotary squeezer and, while still hot, are rolled out into "muck bars." These bars are cut into pieces of from 2 to 4 feet long and are stacked up in piles varying in weight from 100 to 2000 pounds. These piles are heated in a re-heating furnace, and when white hot, are taken to the rolls to be rolled out and welded together into iron bars, sheets, plates, or structural shapes. This material, after re-rolling, is known as refined iron, and if subjected to a second piling, heating and re-rolling, is called double-refined iron. Instead of starting the process with pig

www.EngineeringEBooksPdf.com

iron, as described, scrap iron can also be employed. "Common iron" is wrought iron made from coke pig, whereas finer grades or "charcoal iron" are made from charcoal pig.

Bessemer Process.—In the Bessemer process of making steel, the molten pig iron is put into a large pear-shaped vessel, called the "converter," and the impurities are oxidized and removed by blowing air up through the molten mass. The molten iron (from 10 to 15 tons at a time) is poured into the converter while the latter is in a horizontal position; then the compressed air is turned into the blast box at the furnaces. Electric furnaces permit of very close control of the composition of steel, and alloy additions may be made in the furnace itself rather than in the ladle. It is practicable to use relatively cheap raw materials in the electric furnace. This furnace may be employed for recovering alloy scrap.

Malleable-iron Castings.—Malleable iron is produced by the annealing or graphitization of "white iron" castings. Malleable castings are used for many industrial applications where strength, ductility, machinability, and resistance to shock are important factors. In manufacturing these castings, the usual procedure is to produce first a hard brittle white iron from a charge of pig iron and scrap. These hard white-iron castings are then placed in annealing pots and the graphitization (malleablizing) of the castings is accomplished by means of a suitable heat treatment. During this annealing period the temperature is slowly increased to 1550 or 1600 degrees F., and this temperature is maintained from 48 to 60 hours, after which it is slowly reduced. This malleablizing process is applicable to sections at least 4 inches thick, graphitization occurring throughout the entire section.

Physical Properties of Malleable Iron.—The average values of the tensile strength, yield point, and elongation of malleable iron, based upon approximately twenty thousand tests made by seventeen investigators, are as follows: Tensile strength (pounds per square inch) 54,000; yield point, 36,000; elongation in 2 inches, 18 per cent. The average ultimate shearing strength is about 48,000; the modulus of elasticity in tension, 25,000,000; and, in shear, 12,500,000 pounds per square inch. The average chemical composition is as follows: Carbon, 1.00 to 2.00; silicon, 0.60 to 1.10; manganese, under 0.30; phosphorus, under 0.20; sulphur, 0.06 to 0.15 per cent.

Steel Castings.—Steel castings are especially adapted for machine parts that must withstand shocks or heavy loads. They are stronger than either wrought iron, cast iron, or malleable iron and are very tough. The steel used for making steel castings may be produced either by the Bessemer, open-hearth, electric, or crucible processes. The raw materials used are steel scrap, pig iron, and iron ore, the materials and their proportions varying according to the process and the type of furnace used. Steel for comparatively small castings may be made by the Bessemer or crucible furnaces, whereas for large castings, the open-hearth furnace is preferable. The electric furnace is now used considerably, some of the larger sizes being employed in conjunction with open-hearth furnaces and Bessemer converters which partially refine the charge. Steel castings are used for such parts as cylinder covers, cross-heads, cross-head guides, bearing caps, bedplates, stern-posts for ships, rudder frames, gun mounts, locomotive side frames, etc. They are of special importance in ship construction and for various classes of railway equipment.

There are two very general classes of steel castings — namely, the carbon steel and the alloy steel. The carbon steel castings may have a carbon content ranging from 0.05 to 1.70; manganese, from 0.50 to 1.00; silicon, from 0.20 to 0.75; phosphorus, 0.05 maximum; and sulphur, 0.06 maximum. Low-carbon steels (containing less than 0.20 per cent carbon) may have a tensile strength ranging from 40,000 to 70,000 pounds per square inch. High-carbon steels containing more than 0.40 per cent carbon may have a tensile strength ranging from 70,000 to 120,000 pounds per square inch. The medium-carbon cast steels with a carbon content varying from 0.20 to 0.40 may have a tensile strength varying from 60,000 to 80,000 pounds per square inch. Alloy cast steels contain special elements, such as chromium, nickel, molybdenum, tungsten, etc. These various alloys, in conjunction with suit-

www.EngineeringEBooksPdf.com

able heat-treatments, make it possible to secure steel castings having a wide range of physical properties.

Manganese Steel Castings.—The metal for manganese steel castings is refined in a Bessemer converter from which it is poured into a ladle in which the proper quantity of ferromanganese has been previously placed. Manganese steel castings are generally allowed to cool in the mold, and are then annealed for from 3 to 26 hours at temperatures ranging from 1800 to 2000 degrees F. Unannealed manganese steel castings are exceptionally brittle and almost glass hard. After the heat-treatment, they are tough and ductile with a tensile strength of about 90,000 pounds and an elastic limit of about 60,000 pounds per square inch.

Semi-steel Castings.—What is commonly known as "semi-steel" and less frequently as "toughened cast iron" is produced by adding soft steel or wrought-iron scrap to the charge in a cupola. The semi-steel castings obtained from this mixture are cast in the same manner as ordinary castings. The mixture or charge for making semi-steel castings usually contains about 20 per cent of steel scrap, although any amount up to about 70 per cent may be used. Semi-steel castings have less total carbon than ordinary cast iron, there seldom being more than 3 per cent. The fine grain of semi-steel is due to the low percentage and fineness of the graphitic carbon. Semi-steel is commonly used for large gears, for the tables, saddles, slides, etc., of machine tools, and for parts requiring a good appearance.

The Temper of Steel.—The term "temper" or "carbon-temper" is used by steel makers to designate the proportion of carbon in the steel. The temper marks or numbers are arbitrarily selected; their relation to the percentage of carbon varying with different makers. The following list of tempers and the purpose for which the various steels are adapted is given by Joseph T. Ryerson & Son:

Temper Number	Per Cent Carbon	Tools for which Steel is Adapted
7	0.65 to 0.75	Blacksmiths' hammers, table knives, dies for drop hammers, large hot forgings, flatters, fullers, track chisels and tools.
8	0.75 to 0.85	Large shear knives, punches, chisels, hammers, boilers, boiler makers' tools, lathe centers, etc.
9	0.85 to 0.95	Punches and dies, hand chisels, mining tools, shear blades, etc.
10	0.95 to 1.05	Drills, large milling cutters, axes, taps, reamers, bolt header dies and similar tools.
11	1.05 to 1.15	Granite chisels, milling cutters, taps, reamers, mill picks, threading dies, cups, cones, etc.
12	1.15 to 1.25	Milling cutters, small taps, threading dies, twist drills, forming and boring tools, mandrels, razors.
13	1.25 to 1.35	Inserted milling cutter teeth, lathe, planer and slotter tools, and tools requiring great hardness.
14	1.35 to 1.45	Cutting disks, granite lathe tools, paper knives, engravers' tools, roll corrugating and chilled roll turning tools.
15	1.45 to 1.55	Steel for turning chilled rolls, etc., requiring great hardness.

Meehanite Castings.—Castings produced by the Meehanite controlled process may have various combinations of physical properties to meet different requirements. In addition to a number of general engineering types, there are heat-resisting, wear-resisting and corrosion-resisting Meehanite castings. These castings may be produced in a cupola, open hearth or electric furnace, but the cupola is the most widely used. The patented "Equiblast" system is especially adapted to the production of Meehanite casting.

Physical Properties: The general engineering types have minimum tensile strengths ranging from 30,000 to 55,000 pounds per square inch, and compressive strengths from

www.EngineeringEBooksPdf.com

120,000 to 200,000 pounds per square inch. Some types of Meehanite are adapted to heat-treatment, thus increasing the tensile strength to 75,000 pounds per square inch or higher. The tensile strengths of heat-resisting types vary from 27,000 to 40,000 pounds per square inch, and the compressive strengths from 130,000 to 162,000 pounds per square inch. The general engineering types withstand elevated temperatures so as to meet service requirements for the installation involved for the use of superheated steam in contact with important engine, turbine and similar parts. The corrosion-resisting types of Meehanite castings have a minimum tensile strength of 42,000 pounds per square inch and a compressive strength of 160,000 pounds per square inch.

Applications: Meehanite castings have a wide range of applications. Because of their uniform solidity and density, they are applicable not only for complex sections but for various classes of pressure castings used with water, oil, steam, gas, and other substances. These castings are also used for cylinders and rams of hydraulic presses; for locomotive parts subject to wear such as pistons, cylinder liners, packing rings, cross-head shoes, air compressor parts, grate bars, etc.; truck and trailer brake-drums; gears, retorts, rolls, conveyor chains, part requiring resistance to corrosion growth, etc. The resistance to growth of Meehanite under either continuous high temperatures or alternating high and low temperatures has established it as an essential material in many industrial furnace and high-temperature applications.

In pumping machinery in gravel, cement, mining, crude oil, and chemical plants, the resistance of this metal to abrasion and corrosion is one of its most valuable characteristics. The wear resisting property of Meehanite has given it an important place in the making of dies for forming, pressing, drawing, and stamping metal. By virtue of its hard, tough, and dense structure, the metal does not crush at its edges nor deform or gall, but, on the contrary, work-hardens on the surface, acquiring a glazed skin which greatly increases the life of the die.

Welding: Meehanite castings may be welded by means of the electric arc, using a steel or alloy rod or special cast-iron rod. They may also be welded by gas, using a cast-iron Meehanite or bronze rod.

Alloy Cast Iron.—Alloy cast irons are used for various applications requiring strength and resistance to wear. Numerous compositions provide varying properties suitable for different classes of service. There are eight S.A.E. compositions used for such parts as cylinders, cylinder liners, brake-drums, sprockets, clutch plates, and pistons. These eight compositions contain from 2.80 to 3.40 total carbon; from 0.40 to 0.83 combined carbon; from 0.50 to 0.75 manganese; from 2 to 2.35 silicon. In addition, one or more of the alloying elements chromium, copper, molybdenum and nickel are used, but the kinds and amounts of these alloying elements are not specified because of specific service requirements, variations in foundry practice, possible variations in combinations of the alloying constituents. The tensile strength of alloy cast irons range for some applications from 35,000 to 45,000 pounds per square inch, and from 55,000 to 65,000 for classes of service requiring greater strength.

Nickel Cast Iron: A few compositions of nickel cast irons taken from actual practice are as follows. Crankshafts: Total carbon, 2.75 to 3; silicon, 1.90 to 2.30; manganese, 0.55 to 0.75; nickel, 1 to 1.50; molybdenum, 0.50 to 0.75. Diesel Engine Heads: Total carbon, 3.15; silicon, 1.90; manganese, 0.90; nickel, 1.60; chromium, 0.35; molybdenum, 0.35. Coin Press Parts: Total carbon, 2.75; silicon, 1.75; manganese, 0.80; nickel, 2.50; chromium, 0.40; molybdenum, 0.25.

Nickel-Chromium Cast Iron.—A corrosion- and heat-resistant cast iron having the same coefficient of expansion as plain cast iron at elevated temperatures consists of 28 to 32 per cent nickel, 4 to 5 per cent chromium, and the remainder cast iron. It is very tough, is machineable, and maintains its properties without deterioration at high temperatures. The hardness is from 140 to 240 Brinell, and the tensile strength is approximately 30,000

www.EngineeringEBooksPdf.com

pounds per square inch. This metal is intended for use in contact with plain cast iron or steel — for example, as a liner or insert — where it will attain a higher temperature than its surroundings, and must pass through the heating and cooling cycles without becoming separated from the base metal that surrounds it. Examples of its application are bushings and liners for pumps and compressors that handle hot liquids or vapors and automobile-engine valve-seat inserts.

Drawing Dies Cast from Iron Alloys.—Dies cast from nickel-chromium alloys and heat-treated have proved unusually successful in a number of sheet-metal stamping and drawing operations. The alloy compositions for this service have a nickel content of from 2 to 4 per cent and a chromium content of from 0.75 to 1 per cent. These nickel-chromium alloys can be easily heat-treated, possess a fine grain structure, take a high polish, and eliminate streaking of the metal being formed. Before heat-treatment, the Brinell hardness is between 250 and 300, and the tensile strength ranges from 40,000 to 50,000 pounds per square inch. After heat-treatment, the hardness is from 450 to 550 Brinell, and the tensile strength is between 30,000 and 40,000 pounds per square inch.

In most instances, it is possible to cast dies to such close dimensions that the male and female units will fit within small fractions of an inch even before being filed.

Steel for Cast Crankshafts.—Crankshafts cast from a steel alloy of the following composition have proved successful as applied to the engines of a well-known automobile. Chromium, 0.40 to 0.50 per cent; silicon, 0.85 to 1.10 per cent; manganese, 0.60 to 0.80 per cent; carbon, 1.35 to 1.60 per cent; copper, 1.50 to 2.00 per cent; phosphorus, 0.10 per cent maximum; and sulphur, 0.06 per cent maximum.

Torsion tests conducted on these cast crankshafts show an elastic limit ranging from 88,000 to 96,500 pounds per square inch and an ultimate tensile strength ranging from 128,000 to 130,000 pounds per square inch. The Brinell hardness number varies between 255 and 321.

The alloy for these crankshafts is melted in electric furnaces. The time required to bring the furnace from a cool charge to the pouring time is about 3½ hours. The pouring range is between 2670 and 2700 degrees F. After the cast crankshafts reach normal atmospheric temperature, they are heated in a furnace to 1650 degrees F. within one hour and held at that temperature for twenty minutes. They are then permitted to cool to 1000 degrees F. in air, after which they are reheated to 1400 degrees F. within an hour and held at that temperature for one hour. The crankshafts are discharged from this furnace at a temperature of 1000 degrees F. and placed on a cooling conveyor for delivery to the cleaning room.

Tool Steel.—Tool steel, as the term is used in the machine-building industry, may be defined in a general way as any steel that is suitable for making cutting or certain other classes of tools. Tool steel contains a sufficient amount of carbon so that it will harden if heated above a certain temperature and rapidly cooled. The crucible process formerly was used for making all the high-grade tool steel used for metal-cutting tools and, consequently, the terms “tool steel” and “crucible steel” are often used interchangeably, but at the present time the electric furnace is used extensively for producing tool steel.

Open-hearth Tool Steel.—Open-hearth tool steel is used for a large variety of tools and implements which ordinarily are made from steels containing about 0.65 to 0.85 per cent carbon. These tools include hammers, sledges, pliers, woodworking tools, stone cutters' tools, picks, bars, axes, cheap knives, blacksmith tools, forging dies, agricultural implements, and numerous other products. The extensive use of open-hearth steel in the agricultural field accounts for the name “agricultural tool steel.”

Haynes Stellite.—Haynes Stellite is an alloy of cobalt, chromium and tungsten and is non-ferrous or without iron in its composition. The hardness of this alloy is not materially affected by heat up to 1500 degrees F. and it is actually tougher at red heat than when cold. This important characteristic explains its wide application as a cutting tool material.

www.EngineeringEBooksPdf.com

Haynes Stellite works best when operated at high speed and with a comparatively light feed.

J-Metal: The cutting tool material known as J-Metal is an improved grade of Haynes Stellite. The use of J-Metal results either in higher cutting speeds or in greater production between tool grindings. J-Metal is adapted to various classes of machining operations on practically all kinds of machinable materials, excepting chilled cast iron and manganese steel. The hardness of J-Metal at room temperature is 600 Brinell or Rockwell C, 60–62. It is important to note that the hardness of J-Metal is practically unaffected at red heat and this red hardness is considerably greater than that of high-speed steel.

Haynes Stellite—2400: This is another cobalt-chromium-tungsten alloy. Cutting tools made of this material have greater edge strength and longer economic tool life at even higher speeds than tools made of J-Metal, without reduction of feed or depth of cut. In fact, the speeds and feeds recommended are from 10 to 50 per cent greater than those for J-Metal. This alloy may be used for roughing or finishing cast and forged steels, cast and malleable irons, nitrided, stainless and other alloy steels.

Carbide Tools.—Cemented or sintered carbides are used in the machine building and various other industries, chiefly for cutting tools but also for certain other tools or parts subject to considerable abrasion or wear. Carbide cutting tools, when properly selected to obtain the right combination of strength and hardness, are very effective in machining all classes of iron and steel, non-ferrous alloys, non-metallic materials, hard rubber, synthetic resins, slate, marble, and other materials which would quickly dull steel tools either because of hardness or abrasive action. Carbide cutting tools are not only durable, but capable of exceptionally high cutting speeds. There are different classes of sintered carbides, and various grades in each general class with different combinations of hardness and strength. They are applied to various types of tools for turning, milling, drilling, reaming, etc. Information about the particular grade or type of carbide tool for a given purpose should be obtained directly from the manufacturers. Data from practice on the allowable speeds and feeds will be found in that section of the handbook dealing with this subject:

Tungsten carbide is used extensively in cutting cast iron, non-ferrous metals which form short chips in cutting; plastics and various other non-metallic materials. A grade having a hardness of 87.5 Rockwell A might be used where a strong grade is required, as for roughing cuts, whereas for light high-speed finishing or other cuts, a hardness of about 92 might be preferable. When tungsten carbide is applied to steel, craters or chip cavities are formed back of the cutting edge; hence other carbides have been developed which offer greater resistance to abrasion.

Tungsten-titanium carbide (often called "titanium carbide") is adapted to cutting either heat-treated or unheat-treated steels, cast steel, or any tough material which might form chip cavities. It is also applicable to bronzes, monel metal, aluminum alloys, etc. *Tungsten-tantalum carbide* or "tantalum carbide" cutting tools are also applicable to steels, bronzes or other tough materials. A hardness of 86.8 Rockwell A is recommended by one manufacturer for roughing steel, whereas a grade for finishing might have a hardness ranging from 88.8 to 91.5 Rockwell A.

Graphitic Steel for Punches and Dies.—Graphitic steel contains approximately 1.50 per cent total carbon and around 1.00 per cent silicon, and in one form carries approximately 0.25 per cent molybdenum. It can readily be forged to shape from the "as rolled" condition, but before machining to shape it must always be normalized and annealed; this precipitates part of the total carbon in the form of free graphite, uniformly distributed throughout the steel, and develops the spheroidized pearlitic structure so well suited to good machining. Quenching develops a martensitic structure, the steel reacting in much the same manner as eutectoid tool steel. The resulting dies and punches show remarkable hardness and toughness, and are highly resistant to wear. For water-hardening uses, no molybdenum is added, this type of graphitic steel being known as "Graph-sil." When spe-

www.EngineeringEBooksPdf.com

cial toughness is required or freedom from distortion is essential, the oil-hardening "Graph-mo" is used.

Life of Graphitic Steel Dies.—Graphitic steel has now practically replaced all other types of steel used for dies and punches in the plant of the Timken Roller Bearing Co., Canton, Ohio. Every die or punch made from graphitic steel has shown from two to four times the life of the same part made from the steels formerly used. In many instances, as, for example, in a sizing die, from ten to thirty times the life has been secured. In one case, one of the dies formerly used, when examined after it had sized 10,000 pieces, was not found to be in anywhere nearly as good condition as a graphitic-steel die that had sized 309,000 pieces. Increased die and punch life alone was enough to justify the change, but combined with that, was the lower cost of the steel and the decrease in machining time. Graphitic steel can be machined practically as easily as gray cast iron, which means approximately a 30 to 50 per cent saving in machining time, as compared with the steel formerly used. A reduction of 80 per cent in die-dressing time is also effected.

Even greater is the saving that results from avoiding press shut-downs. The decrease in the number of dies and punches that must be kept in stock to assure continuous operation is also an important item. To all of these saving must be added the saving in production time gained by the capacity of the graphitic-steel dies and punches to stand up under high-speed heavy-duty service without requiring polishing or regrinding during a normal production run; and finally, the greater accuracy and improved appearance of the finished parts must be taken into consideration.

Steels for Dies, Punches and Shears Used on Hot Work.—In the selection of die steels for use in modern forging equipment, special consideration must be given to the resistance of the steel to heat, abrasion, and pressure. It is not possible to select a hot-work steel that will possess maximum ability to meet all of these service conditions. In one case, it will be necessary to select a steel having maximum resistance to heat and to abrasion. In another case, the capacity to withstand pressure, shock, and fatigue will be the governing factor.

Hot-work steels may be classified broadly as the tungsten (or molybdenum) type and the chromium type. The accepted usage of the term "hot-work steels," covers all steels used in manufacturing dies, shears, punches, etc., for use in forging machines, presses, hot trimmers, etc.

Tungsten steels may offer the best resistance to heat and abrasion. Molybdenum possesses heat-resisting properties similar to tungsten, and is sometimes used in analyses in place of tungsten in quantities equal to about one-half the tungsten content. Tungsten is an expensive element, but on jobs where dies operate at high temperatures, tungsten steels prove the most economical. Chromium is next to tungsten and molybdenum in heat-resisting qualities. Chromium steels are used largely in automatic hot-working machines where resistance to repeated impact and to heat are important.

The accompanying table gives the analyses for tungsten and chromium steels with broad limits. The compositions suggested are modified by steel makers to meet specific applications. No simple rule can be laid down for selecting a steel that will best meet the problems of a particular job. A thorough analysis of the job is the only sound basis for an intelligent solution of the problem. In the selection of hot-work steels for forging jobs, designers should not hesitate to draw upon the experience of the steel manufacturer.

Dies can be maintained at a fairly even temperature by providing a large flow of liquid coolant, usually water. The application of a small stream of water may cause localized cooling and heat checking. Long slender punches have a tendency to warp when inadequate coolant is used. An air blast is a safer, although more expensive, method of removing scale and reducing heat.

The effect of abrasion on die life approaches that of heat. In high-speed presses and forging machines, abrasion surpasses heat in its effect on die life, since the dies of these fast machines do not operate at the high temperatures encountered with the slower machines. Abrasion is practically the limiting factor on die life when producing forgings to close tolerances. Tungsten steels, in addition to offering resistance to high temperatures, resist abrasion to a high degree. Lubricants, such as heavy oil or oil mixed with graphite, are often used to reduce abrasive action.

Cold Extrusion.—In simplest terms, cold extrusion can be defined as the forcing of unheated metal to flow through a shape-forming die. It is a method of shaping metal by plastically deforming it under compression at room temperature while the metal is within a die cavity formed by the tools. The metal issues from the die in at least one direction with the desired cross-sectional contour, as permitted by the orifice created by the tools.

Cold extrusion is always performed at a temperature well below the recrystallization temperature of the metal (about 1100 to 1300 degrees F. for steel) so that work-hardening always occurs. In hot extrusion, recrystallization eliminates the effects of work-hardening, unless rapid cooling of the extrusion prevents recrystallization from being completed.

Extrusion differs from other processes, such as drawing, in that the metal is always being pushed under compression and never pulled in tension. As a result, the material suffers much less from cracking. While coining is closely related to extrusion, it differs in that metal is completely confined in the die cavity instead of being forced through openings in the die. Some forging operations combine both coining and extrusion.

The pressure of the punch against the metal in an open die, and the resultant shaped part obtained by displacing the metal along paths of least resistance through an orifice formed between the punch and die, permits considerably higher deformation rates without tearing and large changes in the shape. Extrusion is characterized by a thorough kneading of the material. The cross-sectional shape of the part will not change due to expansion or contraction as it leaves the tool orifice. The term "cold extrusion" is not too descriptive and is not universally accepted. Other names for the same process include impact extrusion, extrusion-forging, cold forging, extrusion pressing, and heavy cold forming. Impact extrusion, however, is more frequently used to describe the production of non-ferrous parts, such as collapsible tubes and other components, while cold extrusion seems to be preferred by manufacturers of steel parts. In Germany, the practice is called Kaltspritzen-a literal translation of which is "cold-squirting."

www.EngineeringEBooksPdf.com

One probable reason for not using impact extrusion in referring to the cold extrusion of steel is that the term implies plastic deformation by striking the metal an impact blow. Actually, the metal must be pushed through the die orifice, with pressure required over a definite period of time. One disadvantage of the terminology "cold extrusion" is the possible confusion with the older, more conventional direct extrusion process in which billets of hot metal are placed in a cylinder and pushed by a ram through a die (usually in a large, horizontal hydraulic press) to form rods, bars, tubes, or irregular shapes of considerable length.

Another possible disadvantage is the connotation of the word "cold". While the process is started with blanks, slugs, tubular sections, or pre-formed cups at room temperature, the internal, frictional resistance of the metal to plastic flow raises the surface temperature of the part to 400 degrees F. or more, and the internal temperature even higher (depending on the severity of the operation). These are still below the recrystallization temperature and the extrusions retain the advantages of improved physical properties resulting from the cold working.

Billet.— A “billet,” as the term is applied in rolling mill practice, is square or round in section and from 1½ inches in diameter or square to almost 6 inches in diameter or square. Rolling mills used to prepare the ingot for the forming mills are termed “blooming mills,” “billet mills,” etc.

Hydraulic Press

Rules and Formulas for Hydraulic Press Calculations.—To find the total pressure of a hydraulic press when the diameter of the ram in inches and the water pressure (gage pressure) in pounds per square inch are given, multiply the area of the cross-section of the ram by the pressure per square inch, and divide by 2000. The result is the capacity of the hydraulic press in tons. The same result may be obtained as follows: Multiply the square of the diameter of the ram by the pressure per square inch, and multiply this product by 0.00039. The result is the total pressure of the press in tons.

The pressure per square inch on the material under pressure in the press can be determined when the total pressure of the press and the area of the material under pressure are known. Multiply the total pressure of the press in tons by 2000, and divide the product by the area of the material to be pressed. The quotient is the pressure in pounds per square inch on the surface of the material.

When a certain pressure per square inch on the material under pressure is required, the gage pressure of the press necessary to obtain this pressure may be calculated as follows: Multiply the area of the surface under pressure by the pressure per square inch desired on the material. Divide this product by 0.7854 times the square of the diameter of the ram. The quotient will be the desired gage pressure.

Expressing these rules as formulas, let D = diameter of ram in inches; P = water pressure in pounds per square inch (gage pressure); C = total pressure or capacity of press in tons; A = area of material to be pressed, in square inches; P_a = pressure in pounds per square inch on material under pressure; then:

$$C = 0.00039D^2 \times P \qquad P_a = \frac{2000C}{A} \qquad P = \frac{A \times P_a}{0.7854D^2}$$

Punches, Dies, and Press Work

Clearance between Punches and Dies.—The amount of clearance between a punch and die for blanking and perforating is governed by the thickness and kind of stock to be operated upon. For thin material, the punch should be a close sliding fit to prevent ragged edges, but for heavier stock, there should be some clearance. The clearance between the punch

www.EngineeringEBooksPdf.com

and die in cutting heavy material reduces the pressure required for the punching operation and the danger of breaking the punch.

Meaning of the Term "Clearance".— There is a difference of opinion among diemakers as to the method of designating clearance. The prevailing practice of fifteen firms specializing in die work is as follows: Ten of these firms define clearance as the space between the punch and die on *one side,* or one-half the difference between the punch and die sizes. The remaining five firms consider clearance as the total difference between the punch and die sizes; for example, if the die is round, clearance equals die diameter minus punch diameter. The advantage of designating clearance as the space on each side is particularly evident with dies of irregular form or of angular shape. Although the practice of designating clearance as the difference between the punch and die diameters may be satisfactory for round dies, it leads to confusion when the dies are of unsymmetrical forms. The term "clearance" should not be used in specifications without indicating clearly just what it means. According to one die manufacturer, the term "cutting clearance" is used to indicate the space between the punch and die on each side, and the term "die clearance" refers to the angular clearance provided below the cutting edge so that the parts will fall easily through the die. The term "clearance" as here used means the space on one side only; hence, for round dies, clearance equals die radius minus punch radius.

Clearances Generally Allowed.— For brass and soft steel, most dies are given a clearance on one side equal to the stock thickness multiplied by 0.05 or 0.06; but one-half of this clearance is preferred for some classes of work, and a clearance equal to the stock thickness multiplied by 0.10 may give the cleanest fracture for certain other operations such as punching holes in ductile steel boiler plate.

Where Clearance Is Applied.— Whether clearance is deducted from the diameter of the punch or added to the diameter of the die depends upon the nature of the work. If a blank of given size is required, the die is made to that size and the punch is made smaller. Inversely, when holes of a given size are required, the punch is made to the diameter wanted and the die is made larger. Therefore, for blanking to a given size, the clearance is deducted from the size of the punch, and for perforating, the clearance is added to the size of the die.

Effect of Clearance on Working Pressure.— Clearance affects not only the smoothness of the fracture, but also the pressure required for punching or blanking. This pressure is greatest when the punch diameter is small compared to the thickness of the stock. In one test, for example, a punching pressure of about 32,000 pounds was required to punch $\frac{3}{4}$-inch holes into $\frac{5}{16}$-inch mild steel plate when the clearance was about 10 per cent. With a clearance of about 4.5 per cent, the pressure increased to 33,000 pounds and a clearance of 2.75 per cent resulted in a pressure of 34,500 pounds.

Soft ductile metal requires more clearance than hard metal, although it has been common practice to increase the clearance for harder metals. In punching holes in fairly hard steel, a clean fracture was obtained with a clearance of only 0.03 times stock thickness.

Angular Clearance for Dies.— The angular clearance ordinarily used in a blanking die varies from 1 to 2 degrees, although dies intended for producing a comparatively small number of blanks are sometimes given a clearance angle of 4 or 5 degrees to facilitate making the die quickly. When large numbers of blanks are required, a clearance of about 1 degree is used.

There are two methods of giving clearance to dies: In one method, the clearance extends to the top face of the die; and in the other, there is a space about $\frac{1}{8}$ inch below the cutting edge that is left practically straight, or having a very small amount of clearance.

For very soft metal, such as soft, thin brass, the first method is employed, but for harder material, such as hard brass, steel, etc., it is better to have a very small clearance for a short distance below the cutting edge. When a die is made in this way, thousands of blanks can

www.EngineeringEBooksPdf.com

be cut with little variation in their size, as grinding the die face will not enlarge the hole to any appreciable extent.

Lubricants for Press Work.— Blanking dies used for carbon and low-alloy steels are often run with only residual mill lubricant, but will last longer if lightly oiled. Higher alloy and stainless steels require thicker lubricants. Kerosene is usually used with aluminum. Lubricant thickness needs to be about 0.0001 in. and can be obtained with about 1 pint of fluid to cover 500 sq. ft of material. During successive strokes, metal debris adheres to the punch and may accelerate wear, but damage may be reduced by application of the lubricant to the sheet or strip by means of rollers or spray. High-speed blanking may require heavier applications or a continuous airless spraying of oil. For sheet thicker than $\frac{1}{8}$ in. and for stainless steel, high-pressure lubricants containing sulfurs and chlorines are often used.

Shallow drawing and forming of steel can be done with low-viscosity oils and soap solutions, but deeper draws require light- to medium-viscosity oils containing fats and such active elements as sulfur or phosphorus, and mineral fillers such as chalk or mica. Deep drawing often involves ironing or thinning of the walls by up to 35 per cent, and thick oils containing high proportions of chemically active compounds are used. Additives used in drawing compounds are selected for their ability to maintain a physical barrier between the tool surfaces and the metal being shaped. Dry soaps and polymer films are frequently used for these purposes. Aluminum can be shallow drawn with oils of low to medium viscosity, and for deep drawing, tallow may be added, also wax or soap suspensions for very large reductions.

Annealing Drawn Shells.— When drawing steel, iron, brass, or copper, annealing is necessary after two or three draws have been made, because the metal is hardened by the drawing process. For steel and brass, anneal between alternate reductions, at least. Tin plate or stock that cannot be annealed without spoiling the finish must ordinarily be drawn to size in one or two operations. Aluminum can be drawn deeper and with less annealing than the other commercial metals, provided the proper grade is used. If it is necessary to anneal aluminum, it should be heated in a muffle furnace, care being taken to see that the temperature does not exceed 700 degrees F.

Drawing Brass.— When drawing brass shells or cup-shaped articles, it is usually possible to make the depth of the first draw equal to the diameter of the shell. By heating brass to a temperature just below what would show a dull red in a dark room, it is possible to draw difficult shapes, otherwise almost impossible, and to produce shapes with square corners.

Drawing Rectangular Shapes.— When square or rectangular shapes are to be drawn, the radius of the corners should be as large as possible, because defects usually occur in the corners when drawing. Moreover, the smaller the radius, the less the depth that can be obtained in the first draw.

The maximum depths that can be drawn with corners of a given radii are approximately as follows: With a radius of $\frac{3}{32}$ to $\frac{3}{16}$ inch, depth of draw, 1 inch; radius $\frac{3}{16}$ to $\frac{3}{8}$ inch, depth $1\frac{1}{2}$ inches; radius $\frac{3}{8}$ to $\frac{1}{2}$ inch, depth 2 inches; and radius $\frac{1}{2}$ to $\frac{3}{4}$ inch, depth 3 inches.

These figures are taken from actual practice and can doubtless be exceeded slightly when using metal prepared for the process. If the box needs to be quite deep and the radius is quite small, two or more drawing operations will be necessary.

Speeds and Pressures for Presses.— The speeds for presses equipped with cutting dies depend largely upon the kind of material being worked, and its thickness. For punching and shearing ordinary metals not over $\frac{1}{4}$ inch thick, the speeds usually range between 50 and 200 strokes per minute, 100 strokes per minute being a fair average. For punching metal over $\frac{1}{4}$ inch thick, geared presses with speeds ranging from 25 to 75 strokes per minute are commonly employed.

www.EngineeringEBooksPdf.com

The cutting pressures required depend upon the shearing strength of the material, and the actual area of the surface being severed. For round holes, the pressure required equals the circumference of the hole × the thickness of the stock × the shearing strength.

To allow for some excess pressure, the tensile strength may be substituted for the shearing strength; the tensile strength for these calculations may be roughly assumed as follows: Mild steel, 60,000; wrought iron, 50,000; bronze, 40,000; copper, 30,000; aluminum, 20,000; zinc, 10,000; and tin and lead, 5,000 pounds per square inch.

Pressure Required for Punching.— The formula for the force in tons required to punch a circular hole in sheet steel is $\pi DST/2000$, where S = the shearing strength of the material in lb/in.^{2}, T = thickness of the steel in inches, and 2000 is the number of lb in 1 ton. An approximate formula is DT × 80, where D and T are the diameter of the hole and the thickness of the steel, respectively, both in inches, and 80 is a factor for steel. The result is the force in tons.

Example: Find the pressure required to punch a hole, 2 inches in diameter, through ¼-in. thick steel. By applying the approximate formula, $2 \times \frac{1}{4} \times 80 = 40$ tons.

If the hole is not circular, replace the hole diameter with the value of one-third of the perimeter of the hole to be punched.

Example: Find the pressure required to punch a 1-inch square hole in ¼-in. thick steel. The total length of the hole perimeter is 4 in. and one-third of 4 in. is 1⅓ in., so the force is $1\frac{1}{3} \times \frac{1}{4} \times 80 = 26\frac{2}{3}$ tons.

The corresponding factor for punching holes in brass is 65 instead of 80. So, to punch a hole measuring 1 by 2 inches in ¼-in. thick brass sheet, the factor for hole size is the perimeter length $6 \div 3 = 2$, and the formula is $2 \times \frac{1}{4} \times 65 = 32\frac{1}{2}$ tons.

Punch and Die Clearance, Amount of Clearance.— The amount of clearance between a punch and die for blanking and perforating is governed by the thickness and kind of stock to be operated upon. For thin material such as tin, for example, the punch should be a close sliding fit, as, otherwise, the punching will have ragged edges, but for heavier stock there should be some clearance. The clearance between the punch and die in cutting heavy material, lessens the danger of breaking the punch and reduces the pressure required for the punching operation. For brass and soft steel, most dies are given a clearance on one side equal to the stock thickness multiplied by 0.05 or 0.06; but one-half of this clearance is preferred for some classes of work, and a clearance equal to the stock thickness multiplied by 0.10 may give the cleanest fracture for certain other operations such, for example, as punching holes in ductile steel boiler plate.

Shut Height of Press.— The term "shut height," as applied to power presses, indicates the die space when the slide is at the bottom of its stroke and the slide connection has been adjusted upward as far as possible. The "shut height" is the distance from the lower face of the slide, either to the top of the bed or to the top of the bolster plate, there being two methods of determining it; hence, this term should always be accompanied by a definition explaining its meaning. According to one press manufacturer, the safest plan is to define "shut height" as the distance from the top of the bolster to the bottom of the slide, with the stroke down and the adjustment up, because most dies are mounted on bolster plates of standard thickness, and a misunderstanding that results in providing too much die space is less serious than having insufficient die space. It is believed that the expression "shut height" was applied first to dies rather than to presses, the shut height of a die being the distance from the bottom of the lower section to the top of the upper section or punch, excluding the shank, and measured when the punch is in the lowest working position.

Depth and Diameter Reductions of Drawn Cylindrical Shells.— The depth to which metal can be drawn in one operation depends upon the quality and kind of material, its thickness, the slant or angle of the dies, and the amount that the stock is thinned or "ironed"

www.EngineeringEBooksPdf.com

in drawing. A general rule for determining the depth to which cylindrical shells can be drawn in one operation is as follows: The depth or length of the first draw should never be greater than the diameter of the shell. If the shell is to have a flange at the top, it may not be practicable to draw as deeply as is indicated by this rule, unless the metal is extra good, because the stock is subjected to a higher tensile stress, owing to the larger blank needed to form the flange. According to another rule, the depth given the shell on the first draw should equal one-third the diameter of the blank. Ordinarily, it is possible to draw sheet steel of any thickness up to $\frac{1}{4}$ inch, so that the diameter of the first shell equals about six-tenths of the blank diameter. When drawing plain shells, the amount that the diameter is reduced for each draw must be governed by the quality of the metal and its susceptibility to drawing. The reduction for various thicknesses of metal is about as follows:

Approximate thickness of sheet steel	$\frac{1}{16}$	$\frac{1}{8}$	$\frac{3}{16}$	$\frac{1}{4}$	$\frac{5}{16}$
Possible reduction in diameter for each succeeding step, per cent	20	15	12	10	8

For example, if a shell made of $\frac{1}{16}$-inch stock is 3 inches in diameter after the first draw, it can be reduced 20 per cent on the next draw, and so on until the required diameter is obtained. These figures are based upon the assumption that the shell is annealed after the first drawing operation, and at least between every two of the following operations. Necking operations—that is, the drawing out of a short portion of the lower part of the cup into a long neck—may be done without such frequent annealings. In double-action presses, where the inside of the cup is supported by a bushing during drawing, the reductions possible may be increased to 30, 24, 18, 15, and 12 per cent, respectively. (The latter figures may also be used for brass in single-action presses.)

When a hole is to be pierced at the bottom of a cup and the remaining metal is to be drawn after the hole has been pierced or punched, always pierce from the opposite direction to that in which the stock is to be drawn after piercing. It may be necessary to machine the metal around the pierced hole to prevent the starting of cracks or flaws in the subsequent drawing operations.

The foregoing figures represent conservative practice and it is often possible to make greater reductions than are indicated by these figures, especially when using a good drawing metal. Taper shells require smaller reductions than cylindrical shells, because the metal tends to wrinkle if the shell to be drawn is much larger than the punch. The amount that the stock is “ironed” or thinned out while being drawn must also be considered, because a reduction in gage or thickness means greater force will be exerted by the punch against the bottom of the shell; hence the amount that the shell diameter is reduced for each drawing operation must be smaller when much ironing is necessary. The extent to which a shell can be ironed in one drawing operation ranges between 0.002 and 0.004 inch per side, and should not exceed 0.001 inch on the final draw, if a good finish is required.

Seamless Tube

Mannesmann Process.— The piercing process used in the production of seamless tubes, commonly called the "Mannesmann process," is based upon the fact that the cross-rolling of a heated round bar of steel produces a rupturing of the material along its center line, and a tendency to form a hole along its longitudinal axis. The diagram illustrates the principle of the Mannesmann piercing process. A round solid billet is passed between two rolls the axes of which are at an angle, as the illustration indicates. These rolls impart to the billet a high rotative speed and a slow advancing movement, forcing the billet over a pointed mandrel and thus increasing its length and changing it from the solid to the tubular form. The forward motion of the billet is caused by the inclination of the axes of the conical rolls relative to each other. A satisfactory explanation for the remarkable results obtained by this method is difficult to give. It seems that the material, instead of flowing in a longitudinal direction, as in ordinary rolling, has a tendency to flow outward toward the circumference, owing to the rotary motion, and a distinct displacement of the fiber takes place. This method of piercing billets can be applied in a number of ways.

Forge Shop Equipment

Blacksmiths' Anvils.— The quality of an anvil can generally be judged by its ring, a good anvil giving out a clear, sharp sound when struck with a hammer. If soft or defective, the sound will be dull. A good anvil so mounted that it gives out a full volume of sound is easier to work upon than one having a dead ring. Anvils ordinarily vary in weight from 150 to 300 pounds. A mistake is often made in selecting anvils that are too light for the service required. A 300-pound anvil is suitable for almost any kind of machine blacksmithing, and, if of this weight or heavier, it will not move around while in use or need to be strapped to its block. The square hole in the face of an anvil for receiving the cutting and forming tools is called the "hardie hole," and the small round hole near it is called the "pritchel hole." Anvils are usually made with a wrought-iron body to which is welded a hardened steel face.

Setting the Anvil.— The height of an anvil should be such that when standing beside if the knuckles of the hands will just reach the top surface or face. A solid oak block set endwise in the ground is often used as a foundation, but a cast-iron mounting block is preferable as it can easily be moved. The casting should have a fairly broad base, and a pocket at the top for receiving the anvil; a flat block of wood is provided to act as a cushion. An anvil should not be strapped rigidly to its foundation, as this checks the vibration which tends to keep the face free from scales, and renders a high-grade wrought-iron anvil little better than one made of cast iron. When a wooden block is used under the anvil, it is necessary to drive in a few spikes to keep the anvil in place, but these should be so placed that they do not bear directly upon or bind against the corners.

Steam Hammer Rating.— The capacity of a steam hammer or its rating is the weight of the ram and its attached parts, such as the piston and rod. The steam pressure behind the piston is not considered as far as the rating is concerned. For example, a 1000-pound hammer has reciprocating parts of that weight. The steam pressures for operating hammers usually vary from 75 to 100 pounds per square inch.

Capacity of Steam Hammers.— Capacity of a steam hammer or the proper size to use for working iron and steel of a given cross-sectional area can be determined approximately by the following rule: Multiply the area of the largest cross-section to be worked by 80, if of steel, or 60, if of iron, and the product will be the required rating of the hammer in pounds. For example, the capacity of a hammer for working steel billets 5 inches square would be determined as follows: $5 \times 5 = 25$; and $25 \times 80 = 2000$, which is the rating of the hammer in pounds. A hammer rated according to this rule is an economical size to use, although it can, of course, be employed for heavier work.

Power for Operating Steam Hammers.— The boiler horsepower for operating a steam hammer depends upon the service required and the number of hammers in use. Ordinarily, the boiler capacity can be less where there are a number of hammers, because all of the hammers are rarely, if ever, used at the same time; consequently, there is a reserve power; but with a single hammer, especially when in constant service, the boiler capacity should be proportionately greater. For average conditions, the boiler horsepower can be determined approximately by the following rule: Divide the rated capacity of the hammer in pounds by 100, and the quotient will be the boiler horsepower required for continuous operation. For example, if the hammer is rated at 2000 pounds, the boiler horsepower would equal $2000 \div 100 = 20$ H.P. This rule is also applicable in cases where the hammer is not used continually, by estimating the amount of idle time and making suitable allowance, but the boiler capacity must not be reduced to such an extent that there is a decided diminution in the pressure during the working period.For foundations for steam hammers, see section on " Machinery and Hammer Foundations."

Board Drop-hammers.— This type of hammer is generally considered superior to the steam hammer for producing drop-forgings of small and medium size. When the work is heavy and requires a great deal of "breaking down" or drawing, or even when the forgings

www.EngineeringEBooksPdf.com

are light, but have thin sections that cool quickly, thus requiring sharp, rapid blows, the steam hammer will usually give better results than aboard drop. The capacity of most of the board drop-hammers in use varies from 800 to 1500 pounds; the steam hammers found in drop forging plants usually range from 2000 to 5000 pounds capacity, for handling average work. It does not seem practicable to build board drops larger than 3000 pounds falling weight, and where the forgings are heavy enough to require a capacity over 1500 or 2000 pounds, steam hammers are usually preferred. The latter type is also preferred in some forge shops for all classes of work. It is generally conceded that the cost of operation and repairs is greater for steam hammers, but the latter has a greater output for a given capacity. The power required for operating board drop-hammers varies considerably with the nature of the work. Very little power is required at the point of "pick up," if the work is practically "die to die; " but when the work is soft and there is no rebound, a great deal more power is required, as the rolls have to pick up a "dead load" from rest and there is tattle kinetic energy in the driving pulleys. When there is a good rebound, with the knock-off properly timed, the board will be moving upward with considerable velocity when engaged by the rolls, and much less power is required. Seasoned maple boards have proved superior to any other kind for board drop-hammers. Paper fiber has been tried with fair results, but at present the cost of this material is too high. For foundations for drop-hammers, see the section *Machinery and Hammer Foundations* starting on page 3236.

Forging Presses.—The power of forging presses for the average line of work is approximately as follows: For mild steel at a fair heat, a pressure of from 3 to 5 tons per square inch on the faces of the tools is generally sufficient, but when swages or dies are used, it may be necessary to double these pressures. For the very hardest steels, the pressure required may be as high as 10 or even 15 tons per square inch, but this is an exceptional case. For small forgings, including such parts as can be made from 8-inch square blooms or 12- by 6-inch flats, a press of 300 tons is sufficient, and for larger forgings, such as those used for heavy marine shafts and cranks, a 3000-ton press is generally considered sufficient and can readily handle a 60-inch ingot. The table above indicates, in a general way, the capacity of presses for handling ingots of various diameters.

Table 3. Capacity of Forging Presses

Capacity of Press, Tons	Maximum Diam. of Ingots, Inches	Capacity of Press, Tons	Maximum Diam. of Ingots, Inches
300	10	1500	36
500	14	2000	48
800	20	3000	60
1200	27	4000	72

www.EngineeringEBooksPdf.com

A press of comparatively small capacity may, with suitable appliances, handle work that is really too heavy for it, but at some sacrifice of speed; for economical operation, there should be ample power. As is generally known, the forging press is superior to the steam hammer for comparatively large forgings, because the hammer tends to spread the surface metal without acting upon the center of the ingot to the required degree. With a press, the forging action goes right to the center of the ingot, as evidenced by the bulging that takes place at the sides, and if there is a cavity in the ingot, forging under the press closes it, whereas a hammer, by spreading the surface metal, may tend to enlarge it. As forgings diminish in size, the difference in favor of the press is less marked. Owing to the recent increase in the operating speed of forging presses, however, they now compete with power hammers in the forging of comparatively light work, and the range of presses has been greatly extended.

Air Pressures and Pipe Sizes for Forges.—Blacksmiths' forges require air pressures varying from 1½ to 6 ounces per square inch. Small forges with the blower close to them are adequately supplied with 1½ ounce pressure. If the blower is some distance away and a long discharge pipe with many bends leads to the forge, even though the latter be small, it may be necessary to carry 3 ounces pressure or more, to overcome the friction in the air ducts. Large forges usually require from 3 to 6 ounces pressure. The table, *Air Pressures and Pipe Sizes for Forges*, gives the diameters of discharge mains for various tuyere sizes and numbers of forges.

American Blower Co.

The Cold Swaging Process.—Cold swaging is a method of reducing or forming steel or other material while cold, by drawing to a point or reducing the diameter, as may be required. This is performed by a machine that causes the work to be struck a large number of successive blows by a pair of dies shaped to give the required form. This process is principally applied to the reduction of wires, rods and tubes, and is the only method by which rolled or plated stock can be reduced without destroying the plating or coating. For this reason, it is largely employed for jewelers' work. It is also extensively used for pointing rods or tubes which are to be drawn. The process is used in the manufacture of needles, bicycle spokes, button hooks, crochet needles, etc.

www.EngineeringEBooksPdf.com

Forging Machines.—Some forging machines are intended especially for bolt and rivet heading, and others for more general work. The form or shape into which a part is forged is governed by dies of the required shape and also by a heading tool or plunger which bends or upsets the heated bar of metal and forces it into the die impression. The die may have a single impression, or two or three impressions may be required in order to forge the part by successive operations.

Dies for Bolt and Rivet Forging Machines.—Bolt and rivet dies used in forging machines are, as a rule, made from steel containing from 0.60 to 0.80 per cent carbon and are hardened and drawn. The heading tool, which must be tougher than the dies, is generally made from steel containing from 0.40 to 0.50 per cent carbon, and is drawn considerably more than the forming dies.

Dies and Tools Used in Hot-pressed Center-feed Nut Machines.—The dies used in hot-pressed center-feed nut machines are usually made from chilled iron castings, the dies being ground to size. It is claimed that dies made from this material will last fully eight times as long as those made from ordinary carbon steel, but as it is somewhat difficult to obtain the proper amount of chill, many manufacturers use a good grade of open-hearth crucible steel instead. A crucible steel which is found to give good results contains from 0.90 to 1.10 per cent carbon. In many cases, vanadium alloy steel is used for dies for nut forging machines. The composition of vanadium steel for dies varies. Two grades of vanadium tool steel are recommended for forging machine dies by the American Vanadium Co., of Pittsburgh, Pa. One is composed of carbon, 0.50 per cent; chromium, from 0.80 to 1.10 per cent; manganese, from 0.40 to 0.60 per cent; vanadium, not less than 0.16 per cent; silicon, not more than 0.20 per cent. The heat-treatment recommended for this steel is as follows: Heat to 1550 degrees F. and quench in oil; then reheat to from 1425 to 1450 degrees F., and quench in water, submerging the face of the die only.

The second kind of vanadium tool steel recommended has the following analysis: Carbon, from 0.65 to 0.75 per cent; manganese, from 0.40 to 0.60 per cent; vanadium, not less than 0.16 per cent; silicon, not more than 0.20 per cent. The heat-treatment for this steel should be as follows: Heat to 1525 degrees F. and quench in water, with only the face of the die submerged. Ordinary carbon tool steel dies should be drawn to a light straw color.

Bulldozer Dies.—Many of the tools or dies used on bulldozers are made of cast iron, in order to reduce the cost, and those parts of the dies which are subjected to wear are faced with hardened steel plates which may readily be replaced, if necessary. Whenever hot punching or cutting is done, high-speed self-hardening steel should be used for the working members of the tool.

Helve Hammers.—Power hammers of the helve type are adapted especially for relatively light forging operations, particularly when a rapid succession of blows is required. Ordinary helve hammers are usually built in sizes ranging from 15 to 200 pounds, this rating being based upon the weight of the hammer head. Some "upright helve" hammers are made in sizes up to 500 pounds.

Vertical Power Hammers.—Vertical power hammers of the crank- and pneumatically-operated types are used for general forging operations, especially on the lighter classes of work. Power hammers of the vertical type usually range in size from 25 pounds up to 500 pounds.

Efficiency of Forging Hammers.—The Heim method for determining the efficiency of forging hammers is based on the results of numerous tests conducted by allowing an ordinary drop-hammer to fall a predetermined distance upon a pure lead cylinder, the height of which is 1.5 times its diameter. The diameters of the cylinders which have been adopted for use in testing various sizes of hammers (with regard to their falling weight) are given in Table 5. The following formula gives the number of foot-pounds of work done by one blow of the hammer:

www.EngineeringEBooksPdf.com

$$\text{Work} = 36.75D^3[8.85A + 13.12(A^2 + A^4)] \text{ foot-pounds}$$

Where D = Diameter of the lead cylinder;

$$A = (H - H_1) \div H$$

H= Original height of the cylinder

H_1= height of the cylinder after being stuck by the hammer.

If the expression inside the brackets in the formula is designated by B, the formula may be expressed in the following form:

$$\text{Work} = 36.75D^3B$$

After the lead cylinder has been struck by the hammer, the value of A is calculated and the number of foot-pounds of work developed by the hammer is then obtained by taking the value of B from Table 6 and substituting in the formula.

Example: Suppose a 100-kilogram (220-pound) hammer striking 180 blows per minute is allowed to strike a lead cylinder, the original dimensions of which are 50 millimeters (1.97 inch) in diameter by 75 millimeters (2.95 inches) high. After the blow has been struck, the resulting height of the cylinder is 48 millimeters (1.90 inch). From the preceding formula:

$$A = \frac{2.95 - 1.90}{2.95} = 0.35$$

B = 4.9, from Table 6

Substituting the values of D and B in the formula for the work done by one blow of the hammer:

$$36.75 \times 1.97^3 \times 4.9 = 1376 \text{ foot-pounds} = \text{work done by one blow.}$$

$$\frac{1376 \times 180}{60} = 4128 \text{ foot-pounds} = \text{work done by one blow.}$$

The maximum power required to drive the hammer is 10.3 horsepower. As one horsepower is equivalent to 550 foot-pounds of work per second, the amount of power consumed by the hammer per second is: $10.3 \times 550 = 5665$ foot-pounds. The efficiency of the is found to be:

$$\text{Efficiency} = \frac{\text{useful work}}{\text{power supplied}} = \frac{4128}{5665} = 72 \text{ percent.}$$

The Heim formula and method of testing may be applied to all types of hammers, but, when used on steam hammers, the test must made while the hammer is running continuously and not when set to deliver a single blow.

Table 5. Dimensions of Lead Plugs Used for Testing Various Sizes of Hammers

Falling Weight of Hammer		Diameter of Lead Cylinder[a]		Falling Weight of Hammer		Diameter of Lead Cylinder	
Pounds	Kilograms	Inches	Millimeters	Pounds	Kilograms	Inches	Millimeters

Machinery and Hammer Foundations

The materials commonly used are concrete, stone, brick, and wood in conjunction with concrete for machines subjected to considerable vertical shock. The principal characteristics of these materials are briefly as follows: Concrete is an ideal foundation material, as it becomes practically one solid piece and is much cheaper than a masonry foundation. Stone, in addition to being strong and durable, has great vibrations absorbing power, but is quite costly. Brick is not so durable as stone, but is cheaper and available everywhere. In building a foundation, provision should be made for the foundation bolts, when these are necessary. Sometimes the bolts are set permanently in the foundation, or they may be placed in pipes and have pockets at the lower ends, thus permitting adjustment or removal, if necessary. The bolts are usually located in the proper position by making a wooden templet in which holes are bored to coincide with the holes in the machine base. The inclination of the sides of a foundation should vary from 1½ to 3 inches per foot from the vertical. The foundation pit should be excavated below the frost line of the locality.

Concrete Foundations.—The timber used for making the forms in which concrete foundations are molded should be about 1 inch thick, dressed on the inner side to give a smooth surface. The form should be braced externally about every 2½ feet, and internally about every foot in height. As the form is being filled, the inside braces can be removed. If pocket molds are used for the lower ends of the bolts, they should be soaked in water two or three hours before using, to prevent their swelling and sticking in the concrete. Do not use concrete that has been mixed over twenty minutes. Ram with hammers weighing about 1 pound per square inch of face area, the ramming being continued until water just shows at the surface.

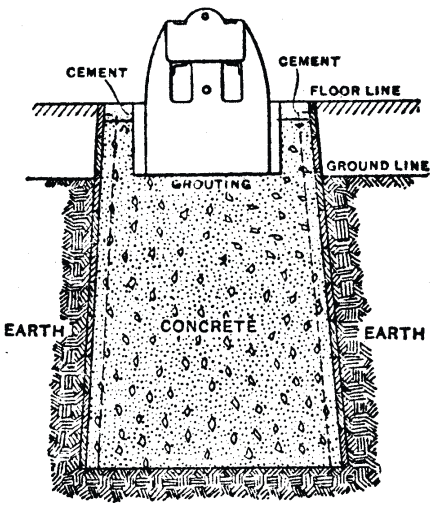

Fig. 1.

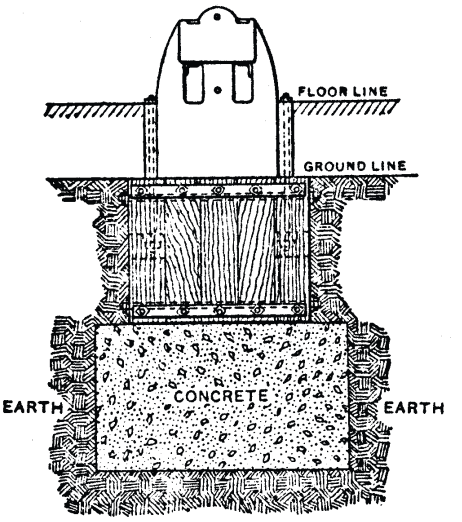

Fig. 2.

Put down the concrete in layers about 6 inches thick and work it onto the form with a shovel, to obtain a smooth, even surface. The foundation may be partly filled with stones about the size of a man's head, placed approximately one foot apart and not less than one foot from the foundation surfaces. These stones should be wet before laying. If the work is stopped at night before completion, make grooves in the surface and when starting the next day, sprinkle and dust over with dry cement. As soon as the concrete has set, remove the

www.EngineeringEBooksPdf.com

form, as it is much easier to patch when the cement is somewhat "green." Foundations are sometimes "slushed" instead of being rammed. In this case, the concrete is mixed just wet enough so that it cannot be piled up. It is then dumped into the molds and worked in them to prevent air bubbles. The first method gives a more homogeneous structure as there is no chance for the broken stones to settle. When the machine is in position, the space around the foundation bolts may be filled with liquid cement, lead or melted sulphur.

Drop Hammer Foundations.—The following drop-hammer foundations are recommended by the E. W. Bliss Company:

Concrete Foundation: : Excavate a hole from 10 to 14 feet deep and from 8 to 12 feet square; build up a block of concrete with tapering sides, as shown in Fig. 1,having a top about 6 to 12 inches wider, all around, than the base of the anvil. Place the anvil in position and wedge it level; then run a thin mixture of concrete the anvil and allow it to set. Next move the wedges and build up a wall of concrete from 4 to 6 inches thick around the anvil. (See Fig. 1 and Fig. 2) This will make the use of bolts unnecessary and the anvil will set solid and will not be likely to shift. Solid concrete makes an excellent foundation that does not deteriorate, as is the case with timber when subjected to dampness from the earth or atmospheric moisture. Another advantage is that it is almost impervious to sparks or hot pieces of metal.

Timber Concrete Foundations: Excavate a hole somewhat larger than the anvil or base of the hammer. At the bottom lay a bed of concrete from 1 to 2 feet thick, as shown in Fig. 2. On this concrete bed place, endwise, Georgia pine timbers 12 by 12 inches by 6 to 8 feet long. These should be securely strapped together by steel bands on the outside fastened with through bolts. The timber base should preferably be a little larger than the anvil. To preserve the timbers coat them with oil of tar or creosote. The tops of the timbers should be dazed off evenly to obtain a level surface for the anvil. Another method of making a foundation of this kind, for small and medium sized hammers, is to put the timbers upon a foot or more of gravel rammed down on a hard-pan bottom. When the timbers, which are also placed endwise and bolted, are in position, the space around the sides is filled with gravel tightly rammed.

Foundation for Steam Hammer.—To secure the greatest efficiency from steam power hammers, the foundations on which they are mounted must be solid concrete resting upon hard-pan has given better results than the combination of heavy wooden beams and concrete often used. When making solid concrete foundations, there should be several inches of cement placed over the concrete, and a cushion of wood, at least 3 inches tuck, between the cement and base of the anvil, to give the necessary resiliency and prevent the concrete from being pulverized by the impact of the blows. In the front and rear of the hammer there should be openings down to the level of the anvil base, so that it can be leveled or adjusted by wedging and grouting with cement, in case it should sag or get out of alignment with the upper parts of the hammer. These openings can be covered with hatches set level with the floor.

Machine and Forge Shop Floor Materials

Machine shop floors are commonly made of wood or concrete. Probably there is no floor for the machine shop as good as one made of selected hard maple, properly laid and supported, as it wears smoothly and evenly. Concrete, however, has its advantages, the most important of which is its fire-resisting qualities. There are few objections to a wooden floor, and from the standpoint of health it is generally considered superior to concrete. Where there is much heat, or large quantities of moisture or chemicals in bulk, wooden doors should not be used. In certain classes of store-rooms, or where there is a likelihood of considerable moisture, as in wash rooms, concrete floors are considered superior to wood.

Concrete and Wooden Floors.—The following information on shop floors and their materials is abstracted from a paper by Mr. L. C. Wason read before the American Society

www.EngineeringEBooksPdf.com

of Mechanical Engineers. While the factor of cost is to be considered first, very often the maintenance and adaptability for the particular Service required is of first importance. The initial cost of a granolithic floor surface is at no disadvantage compared with a wooden floor, as the cost of such a surface laid in the best manner is about equal to the cost of seven-eighths maple flooring. In addition, the granolithic surface is fire-proof and will not decay or disintegrate as the result of moisture, which is one of the weak points of the wooden floor. On the other hand, a wooden floor is more easily repaired than a granolithic surface. In making a comparison between wooden and granolithic floors, it is also necessary to consider the workmanship. With a maple top floor, the wearing quality depends comparatively little on the skill of the one who lays the floor, but with a granolithic finish, the work must be done care fully and intelligently. Among the objections to the granolithic surface, one of the most prominent is the bad effect of a concrete floor upon the health and comfort of the workmen. This is not due to the hardness of the floor, but rather to its heat conductivity. When a workman stands for hours on a concrete floor, the heat of the body is conducted to the floor quite rapidly, which tends to disarrange the circulation and cause physical ailments, such as rheumatism, etc. For men working steadily at machines, and usually in one position, this objectionable feature can be overcome by the use of insulating foot-boards or wooden gratings upon which to stand.

The dust produced by the wear of some granolithic surfaces has proved harmful to delicate machinery, whereas a wooden floor does not of itself produce a dust capable of any appreciable abrasive action. It is possible, however, by gluing battleship linoleum to concrete floors, to obtain many of the advantages of a wooden surface. Linoleum is also an effective insulation against the loss of bodily heat. High resistance to wear and practically complete dustlessness can be secured in a granolithic surface if properly made. To secure a durable and practically dustless floor, proceed as follows: Do not use sand, as sand grains are quickly broken by abrasion and form dust. The granolithic finish should contain the highest possible proportion of tough stone aggregate. Use stone suitable for macadam road, and of a size that will pass through a half-inch round mesh screen, but use nothing smaller than that passed by a 20-mesh screen. Mix the concrete dry, and of a consistency for making blocks, so that considerable tamping will be required to bring enough water to the surface for troweling. Finally, do the troweling before the mortar sets. Prolonged troweling of a wet mixture brings to the top the "laitance" of the concrete, which is the part incapable of a true set. A top layer of laitance is therefore porous and wears down quickly. Even the fine particles of good cement should not be brought to the surface, as they form a layer which is weakly bonded to the rest of the concrete and wears away rapidly, appearing in the air as dust.

Prevent Dust on Concrete Floors.—The Aberthaw Construction Co. of Boston, contracting engineers specializing in concrete, recommends the following method of curing a dusty concrete floor: Have the surface entirely dry; then paint it with a mixture of boiled linseed oil thinned with gasoline. Apply several coats, until the oil shows glossy on the top. The theory of this is that the linseed oil, having been boiled, has lost most of its volatile components and is practically permanent. The gasoline thins this down enough so that it will strike into the pores. A little experimenting will show the proper proportions. The thinner it is, the more coats will be required and the deeper it will strike in. A floor that is causing serious trouble from dust can often be cured with very little trouble and expense in this way.

Floors for Forge Shops.—There is considerable difference in opinion as to the best material for blacksmith shop flooring. Wood is too inflammable, bricks crack and break from the heat, cement or concrete has the same objectionable features, and asphalt is out of the question. Perhaps nothing is superior to or cheaper than dirt mixed with ashes. If kept moist by sprinkling at least once a day, it is more comfortable to stand upon than the other materials mentioned. It is easily repaired and leveled in case holes are worn in it, and is not affected by dropping heavy or hot pieces upon it. The space between the walls and forges,

www.EngineeringEBooksPdf.com

however, may be covered with concrete to facilitate the handle of such appliances as portable surface-plates and vises.

Drop-Forging Dies

Steel for Drop-forging Dies.— Practically all drop-forging dies are made of high-grade open-hearth steel. A 60-point carbon steel is mostly used, although steel as low as 40-point and as high as 85-point carbon is employed in some cases. A special hardening treatment is required for the low-carbon steel, which more than offsets the saving in price, and, except in special cases, there is no advantage in using high-carbon steels, owing to the expense. The average 60-point carbon steel die, if properly hardened, should last for from 15,000 to 40,000 forgings, and sometimes as many as 70,000 forgings can be made from one set of dies. When making dies for large forgings, it is often thought advisable to use 80-point carbon steel, and not harden the dies. This obviates the danger from "checking" or cracking in hardening, and the un-hardened steel is hard enough to resist the tendency to stretch. A steel that is quite high in carbon should always be used for dies that are intended for making forgings from tool steel or any other hard steel.

Allowance for Shrinkage.— When making dies for small cold-trimmed steel forgings, the proper allowance for shrinkage is $\frac{3}{16}$ inch to the foot, or 0.015 inch to the inch. Such forgings are finished at a bright red heat and the rate of shrinkage is considerable. When making dies for hot-trimmed steel forgings of medium and large sizes, the shrinkage allowance is $\frac{1}{8}$ inch to the foot, or 0.010 inch to the inch. Hot-trimmed forgings receive the finishing blow while comparatively cold, and shrink a smaller amount than the cold-trimmed forgings. The foregoing allowances are used for all dimensions of the die impression, such as depth, width or length. The shrinkage allowance for dies to be used in forging bronze or copper is practically the same as that for steel.

Draft Allowance.— The amount of draft in a drop-forging die varies from 3 to 10 degrees. If the die is for a thin forging of uniform section, 3 degrees is ample, but if the forging is deep and has narrow ribs which are apt to stick, at least 7 degrees is necessary. If a die is used for forging a piece that is ring-shaped or has an annular part, the central plug that forms the interior of the ring should have a draft of 10 degrees, because, as the forging cools while being worked, it tends to shrink around the plug and if the draft is insufficient, it will stick in the die. With the foregoing exception, most drop-forging dies have a 7-degree draft. For convenience in laying out, it is well to remember that a 7-degree taper is approximately equal to a $\frac{1}{8}$-inch taper to the inch, and a 10-degree taper, $\frac{3}{16}$ inch to the inch.

Locating Impression in the Die.— When laying out a drop-forging die, the impression should be located so that the heaviest end of the forging will be at the front of the die-block. This makes the forging easier to handle and also permits the use of a fairly large sprue. There should be at least $1\frac{1}{2}$ inch left all around between the impression and the outside edge of the block. This also holds true for any part of the die, such as the edger, anvil or forming impression. If the forging has a hub or other projection that extends some distance from the main part on one side, the upper or top die should contain this deeper impression.

Obtaining Weight of Forging from Lead Proof.— After the upper and lower dies have been completed, shrinkage allowances and the general finish of the impressions are ordinarily tested by taking a "lead proof," and by weighing the lead, an approximate idea of the weight of the finished forging can be obtained. Roughly speaking, the finished forging will weigh two-thirds as much as the lead proof. The shrinkage of lead is practically the same as that of steel, so that the finished forging will also measure about the same as the one made of lead. In case of dies for eye-bolts and similar work, this rule must be disregarded, because the plugs that form the central opening will prevent the lead from shrinking naturally. When taking the lead proof, the die impressions are dusted with powdered chalk, and after the dies are clamped together, the molten lead is poured.

www.EngineeringEBooksPdf.com

Amount of Flash for Drop-forging Dies.—Theoretically, there should be just enough forging metal in a die to fill the impression, and no more, but this is, of course, not practicable, as there is always some stock that must be disposed of after the impression is filled. To take care of this excess metal, dies are relieved all around the impression by milling a flat shallow recess about $\frac{1}{64}$ inch deep and $\frac{5}{8}$ inch wide. These dimensions are for dies of average size; in comparatively large dies this recess or "flash" would be a little deeper and wider. Both the upper and lower dies are flashed in this way. In addition, the upper die is "back-flashed," which means that there is a deeper recess, sometimes called the "gutter," milled around the impression at a distance of $\frac{1}{4}$ inch from the impression at every point. This back-flash is $\frac{3}{64}$ inch deep and acts as a relief for the excess metal after it has been squeezed from the flash proper. Only the finishing impression is provided with a flash and back-flash.

The Break-down of Drop-forging Dies.—The width of section used as a break-down (also known as the edger or side cut) should be enough wider than the forging to give plenty of room for the work of forging. A forging 1 inch thick should have a break-down $1\frac{1}{2}$ inch wide, and about the same proportions should be followed for forgings of other widths. The break-down should have a section corresponding with the gate and sprue of the die impression, but it should be made slightly longer, so that the forging will not be stretched when struck in the impression.

Hardening Drop-forging Dies.—Dies to be carburized should always packed for hardening in cast-iron or sheet-iron boxes containing a mixture of fresh bone and charcoal. The ordinary mixture is half bone and half charcoal. More bone gives greater hardness and more charcoal, less hardness, for a given heat; hence, the proportions should be varied according to requirements. The die should be packed face down on a one- or two-inch layer of this mixture and be settled so that the impression is filled. Sometimes the face is coated, before packing, with a thick paste of linseed oil and powdered bone-black, to protect the delicate edges from oxidation when in contact with the air. Fill the space between the sides of the die and the box with the bone and charcoal mixture, and cover over with a thick layer of wet clay paste to prevent the charcoal from burning out. Dies made of steel having less than 60-point carbon content should always be carburized. Open-hearth steel dies containing 60-point carbon or over can be hardened without carburizing.

Heating the Die.—An oil or gas furnace is recommended for heating, although a coal or coke-fired muffle furnace, capable of maintaining a temperature of at least 1600 degrees F., may be used, provided the temperature can be held constant. A temperature indicating device is necessary. The die should be put into the furnace as soon as the latter is lighted. If the correct quenching temperature for the steel is, say, 1500 degrees F., the furnace should be checked when the pyrometer indicates 1400 degrees, the die being allowed to "soak" at that heat for three or four hours. Then the heat should be slowly raised to 1500 degrees and held at that point one or two hours longer, according to the size of the die. Five hours is the minimum total time for heating, and seven or eight hours is much safer. A 60-point carbon die should be quenched between 1425 and 1450 degrees F.

Cooling the Heated Die.—When cooling, the face of the die should receive a sufficient flow of cold water to cause it to harden to the greatest possible depth. The back of the die should, at the same time, be cooled to make the shrinkage of the face and back equal, and to prevent warping. A good form of cooling tank is one having a large supply pipe extending up through the bottom for cooling the die face, and a smaller pipe above the tank to cool the back. Unless a jet of water under pressure is applied to the face of the die, the sunken parts of the impression will not harden equally with the face. Dies should not be cooled in a tank of still water, because steam forms in the die cavity which prevents the water from entering, thus causing the formation of soft spots. To overcome this, the water must be forced into the impression by pressure sufficient to overcome the resistance of the steam thus formed. Oil should not be used for hardening hammer dies, as its cooling action is not great

www.EngineeringEBooksPdf.com

enough to produce a sufficient depth of hardening. Hammer dies which are simply surface hardened will not withstand the heavy blows received in service. To secure a greater hardening effect, brine of about 40 per cent solution is used by some die-makers.

Tempering Dies.— Dies should be tempered and drawn as soon as they are cool enough to remove from the tank. The dies should be heated in an oil bath, and quenched in water or cool oil. Any high-grade cylinder oil of high flash-point is suitable. Low-grade oils smoke unpleasantly and will not stand high temperatures. The drawing temperature of die steels is about 450 degrees F., for average conditions. The corners of the die and the cut-off should be drawn to a purple color with the aid of a blow torch.

Tempering by the Color Method.— Hardened steel can be tempered or made softer and less brittle by re-heating it to a certain temperature (depending upon the nature of the steel and its intended use), and then cooling. When steel is tempered by the color method, the temper is gaged by the colors formed on the surface as the heat increases, but the color method of gaging temperatures is not dependable, as the color is affected, to some extent, by the composition of the metal. The modern method of tempering, especially in quantity, is to heat the hardened parts to the required temperature in a bath of molten lead, heated oil or other liquids; the parts are then removed from the bath and quenched. The bath method makes it possible to heat the work uniformly, and to a given temperature within close limits.

High Temperatures Judged by Color, and Colors for Tempering

Degrees Centigrade	Degrees Fahrenheit	High Temperatures Judged by Color	Degrees Centigrade	Degrees Fahrenheit	Colors for Tempering
400	752	Red heat, visible in the dark	221	430	Very pale yellow
474	885	Red heat, visible in the twilight	227	440	Light yellow
525	975	Red heat, visible in the daylight	232	450	Pale straw-yellow
581	1077	Red heat, visible in the sunlight	238	460	Straw-yellow
700	1292	Dark red	243	470	Deep straw-yellow
800	1472	Dull cherry-red	249	480	Dark yellow
900	1652	Cherry-red	254	490	Yellow-brown
1000	1832	Bright cherry-red	260	500	Brown-yellow
1100	2012	Orange-red	266	510	Spotted red-brown
1200	2192	Orange-yellow	271	520	Brown-purple
1300	2372	Yellow-white	277	530	Light purple
1400	2552	White welding heat	282	540	Full purple

1600	2912	Dazzling white (bluish-white)	293	560	Full blue
			299	570	Dark blue

Dies for Bronze and Copper Forgings.— Dies for producing drop-forgings from bronze or copper differ from those used for steel or iron forgings principally in the matter of finish. Owing to the softness of copper and bronze, the metal is driven into very minute impressions in the surface of the dies; hence, these surfaces must be perfectly free from scratches, in order to insure a smooth finish on the work. Even though these metals are soft, the hammering necessary when forging is very hard on the dies, and to prevent them from dishing or spreading, tool steel is ordinarily used, unless the forgings are extra large and heavy. The shrinkage, draft and finish allowances on this class of drop-forging dies are practically the same as on dies for steel and iron.

Trimming Dies for Drop-forgings.— Hot-trimming dies are made of a special grade of steel known as hot-trimming die-stock. The objection to use ordinary tool steel for hot-trimming dies is that the edges of a hardened die check badly after the die has been used for a short time, and this checking is followed by a breaking away of the steel around the edges, thus rendering the die unfit for use. This special steel requires no hardening, and after the die is in use, the edges toughen and give better service than the best hardened tool steel. The usual form of punch for hot-trimming dies merely supports the forging while it is being pushed through. If the forging has a broad, flat top face, the punch need only be a little more

www.EngineeringEBooksPdf.com

than a flat piece that covers the forging and acts as a pusher. Such punches are commonly made of cast iron. Cold-trimming dies are made from good tool steel of from 1.00 to 1.25 per cent carbon, and hardened and drawn to a dark straw color. The punches for cold trimmers are also made of tool steel and are hardened and drawn to a very dark straw color. These punches are hardened to prevent them from upsetting at the edges. As with hot-trimming punches, the punch should fit the die loosely, but it should support the forging at every point while it is being pushed through the die. There are two instances in which trimming punches should fit the dies as closely as the average punching die for sheet metal work; first, when trimming forgings on which the fin comes at the corner of the forging; second, forgings that are formed all in one die, the other die being flat. In these two cases, unless the dies fit very well, there will be burrs at the trimmed edges.

Standard Tolerances for Forgings.— The tolerances adopted by the Drop Forging Association in 1937 (see accompanying Tables 1a through 1e) apply to forgings under 100 pounds each. Forging tolerances may either be "special" or "regular." *Special tolerances* are those which are particularly noted in the specifications and may state any or all tolerances in any way as required. Special tolerances apply only to the particular dimensions noted. In all cases where special tolerances are not specified, regular tolerances apply.

Table 1a. Standard Tolerances for Forgings Adopted, 1937, by Drop Forging Association for Forgings under 100 Pounds Each

Thickness Tolerances, Inch[a]									
Net Weights, Pounds, up to –	Commercial		Close		Net Weights, Pounds, up to –	Commercial		Close	
	–	+	–	+		–	+	–	+
.2	.008	.024	.004	.012	20	.026	.078	.013	.039
.4	.009	.027	.005	.015	30	.030	.090	.015	.045
.6	.010	.030	.005	.015	40	.034	.102	.017	.051
.8	.011	.033	.006	.018	50	.038	.114	.019	.057
1	.012	.036	.006	.018	60	.042	.126	.021	.063
2	.015	.045	.008	.024	70	.046	.138	.023	.069
3	.017	.051	.009	.027	80	.050	.150	.025	.075
4	.018	.054	.009	.027	90	.054	.162	.027	.081
5	.019	.057	.010	.030	100	.058	.174	.029	.087
10	.022	.066	.011	.033					

[a] Thickness tolerances apply to the over-all thickness. For drop-hammer forgings, they apply to the thickness in a direction perpendicular to the main or fundamental parting plane of the die. For upset forgings, they apply to the thickness in the direction parallel to the travel of the ram, but only to such dimensions as are enclosed by the actually formed by the die.

www.EngineeringEBooksPdf.com

Table 1b. Standard Tolerances for Forgings Adopted, 1937, by Drop Forging Association for Forgings under 100 Pounds Each

Shrinkage		Plus		Die Wear		Mismatching		
Lengths or widths up to – in.	Commercial + or –	Close + or –	Net wt. up to – lbs.	Commercial + or –	Close + or –	Net Weights, Pounds, up to –	Commercial	Close
1	.003	.002	1	.032	.016	1	.015	.010
2	.006	.003	3	.035	.018	7	.018	.012
3	.009	.005	5	.038	.019	13	.021	.014
4	.012	.006	7	.041	.021	19	.024	.016
5	.015	.008	9	.044	.022	25	.027	.018
6	.018	.009	11	.047	.024	31	.030	.020

For each additional inch under shrinkage, add 0.003 to the commercial tolerance and 0.0015 to the close tolerance. For example, if length or width is 12 inches, the commercial tolerance is plus or minus 0.036 and the close tolerance plus or minus 0.018.

For each additional 2 pounds under die wear, add 0.003 to the commercial tolerance and 0.0015 to the close tolerance. Thus, if the net weight is 21 pounds, the die wear commercial tolerance is 0.062 plus or minus, and the close tolerance 0.031 plus or minus.

For each additional 6 pounds under mismatching, add 0.003 to the commercial tolerance and 0.002 to the close tolerance. Thus, if the net weight is 37 pounds, the mismatching commercial tolerance is 0.033 and the close tolerance 0.022.

These quantity tolerances represent the permissible over-run or under-run allowed for each release or part shipment of an order. Any shipping quantity within the limits of over-run or under-run shall be considered as completing the order.

Table 1e. Standard Tolerances for Forgings Adopted, 1937, by Drop Forging Association for Forgings under 100 Pounds Each

Maximum Radii of Fillets and Corners, Inch					
Net Weights, Pounds, up to —	Commercial	Close	Net Weights, Pounds, up to —	Commercial	Close
.3	3/32	3/64	10	3/16	3/32
1	1/8	1/16	30	7/32	7/64
3	5/32	5/64	100	1/4	1/8

Regular tolerances: are divided into two divisions — "Commercial Standard" and "Close Standard." "Commercial Standard" tolerances are for general forging practice, but when extra close work is desired involving additional expense and care in the production of forgings, "Close Standard" may be specified. When no standard is specified, "Commercial Standard" shall apply.

Regular tolerances are applicable to 1) thickness; 2) width, including shrinkage and die wear, mismatching, and trimmed size; 3) draft angle; 4) quantity in shipment; and 5) fillets and corners.

Thickness Tolerances: Thickness tolerances shall apply to the overall thickness of a forging. (See Table 1a.)

Width and Length Tolerances: Width and length tolerances shall be alike and shall apply to the width or length of a forging. When applied to drop hammer forgings, they shall apply to the width or length in a direction parallel to the main or fundamental parting plane of the die, but only to such dimensions as are enclosed by and actually formed by the die. When applied to upset forgings, they shall apply to the width or length in a direction perpendicular to the direction of travel of the ramp.

Width and length tolerances consist of the three subdivisions following: a) Shrinkage and die wear tolerance; b) mismatching tolerance; and c) trimmed size tolerance.

Welding Methods

Classes of Welds.—Welds are classified according to the way the ends are formed prior to making the weld. The different welds ordinarily made in hand forging practice are the scarf weld, butt weld, lap weld, cleft or split weld and jump weld. These welds are shown by the accompanying illustration. It will be seen that the surfaces, in most instances, are rounded or crowned. This is done so that when the heated ends are brought together they will unite first in the center. Any slag or dirt which may have adhered to the heated surfaces will then be forced out as the welding proceeds from the center outward. When making a lap weld, the hammering should begin at the center in order to work all the slag out, as the faces in this case are not rounded.

Welding Heat.—When two pieces of wrought iron or mild steel are heated until they become soft and plastic and will stick together when one is pressed or hammered against the other, they have reached what is commonly known as a welding heat. The quality of the weld depends largely upon the welding heat. If the ends to be heated are not hot enough, they will not stick together; inversely, if the work remains in the fire too long, it becomes overheated and burned, which greatly injures the metal. Iron which has been overheated has a rough, spongy appearance and is brittle. The danger of burning is increased when the air blast is too strong and the fire is oxidizing. It is important to heat the work slowly to secure a uniform temperature throughout the ends to be heated. With rapid heating, the out-

www.EngineeringEBooksPdf.com

side may be raised to the welding temperature, while the interior is much below it; consequently, the weld will be defective.

Fire for Welding.—When heated iron comes into contact with the air it absorbs oxygen, thus forming a scale or oxide of iron on the surface, which prevents the formation of a good weld. A fire for heating parts to be welded should have a fairly thick bed between the tuyere and the work, so that the oxygen in the air blast will be consumed before it reaches the parts being heated. When there is only a thin bed of fuel beneath the work, or if too strong a blast is used, the excess of oxygen will pass through and oxidize the iron. The hotter the iron, the greater the formation of scale. The surface being heated can be given an additional protection by covering it with some substance that will exclude the air. (See *Fluxes for Welding*.) Ordinarily, the air blast for a forge fire should have a pressure varying from 3 to 6 ounces per square inch. (See *Air Pressures and Pipe Sizes for Forges* on page 3233.)

Fluxes for Welding.—When iron is being heated preparatory to welding, the heated surfaces are oxidized to some extent or covered with oxide of iron, which forms a black scale when the hot iron comes into contact with the air. If this scale is not removed, it will cause a defective weld. Wrought iron can be heated to a high enough temperature to melt this oxide so that the latter is forced out from between the surfaces by the hammer blows; but when welding machine steel, and especially tool steel, a temperature high enough to melt the oxide would burn the steel, and it is necessary to use what is called a flux. This is a substance, such as sand or borax, having a melting temperature below the welding temperature of the work, and it is sprinkled upon the heated ends when they have reached about a yellow heat. The flux serves two purposes: It melts and covers the heated surfaces, thus protecting them from oxidation, and, when molten, aids in dissolving any oxide that may have formed, the oxide melting at a lower temperature when combined with the flux. Wrought iron can be welded in a clean, well-kept fire without using a flux of any kind, except when the material is very thin. The fluxes commonly used are fine clean sand and borax. When borax is used, it will give better results if burned. This can be done by heating it in a crucible until reduced to the liquid state. It should then be poured onto a flat surface to form a sheet; when cold, it can easily be broken up and pulverized. The borax powder can be used plain or it can be mixed with an equal quantity of fine clean sand and about 25 per cent iron (not steel) filings. For tool steel, a flux made of one part sal-ammoniac and twelve parts borax is recommended. When pieces are put together previous to welding, as in split welds, or when taking a second heat (usually termed a "wash"), a flux that will flow easily should be used. There are many welding compounds on the market, some of which are suited for one class of welding and some for another.

Steel which is very low in carbon can easily be welded, but it cannot be hardened; when the carbon is above 0.33 per cent, welding is more difficult and can be done only by the use of borax or some other flux, or by the electric or thermit processes.

Welding, Resistance Forge.— Resistance forge-welding is a process of heavy-duty electric resistance welding which enables the spot-welding of structural steel and iron sections formerly considered impossible to weld with conventional equipment. The method consists of first applying pressure to the work, then interrupted current, and finally superimposing a hammering action on the electrode. Under high pressure and with sufficient heat, the surfaces of the work are brought into intimate contact, so that when additional impact pressure and intermittent heat are applied, a forged weld of superior quality is obtained.

Fuels for Forge.—Coke, coal, charcoal, oil and gas are used as fuels for heating iron and steel preparatory to forging or welding. For general work, a coke fire is the best, although bituminous coal is extensively used. With anthracite coal, it is difficult to get a hot enough fire, especially on a small forge. Coke or bituminous coal should be low in sulphur, because sulphur makes the iron "hot short" or brittle while hot. Sulphur, lead, bronze or brass must not be in the fuel or fire to be used for heating iron or steel. A weld may be spoiled by throwing brass filings into a fire before heating the work.

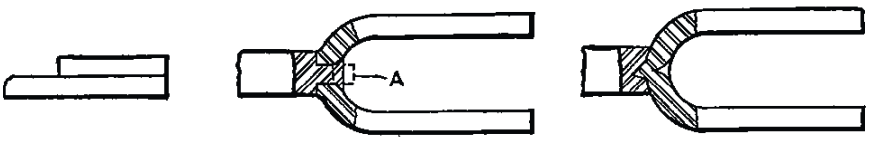
www.EngineeringEBooksPdf.com

Machine Welding.—There are three common types of welds that can be made satisfactorily in a forging machine, simple examples of which are shown in the accompanying illustration.

Lap-welding: This is one of the most successful methods that can be used in joining pieces together in a forging machine, whenever requirements will permit. There are several applications of this type of welding: Two pieces can be joined together (as shown in the illustration) or several pieces can be welded together in one block. Machine lap-welding is also employed for enlarging the diameter of a bar, this being accomplished by welding a U-shaped piece of rectangular stock to the end, and then upsetting the mass into the shape desired. An end plunger is used to upset the bar after the latter is securely held between the opposing faces of the gripping dies.

Pin-welding: In order to make a pin weld, the end of the bar is reduced and inserted in a hole in the part to which it is to be joined (see illustration). The reduced end is usually made from one-quarter to one-half the diameter of the original bar. The U-shaped piece, or other part which is to be joined to it, is generally made thicker where the weld is made, in order to strengthen the weld. The welding operation is effected by a plunger in the ram of the machine, which upsets the "pin" and at the same time forms the joint.

Butt-welding: This method of machine welding is not as common as the other two methods referred to, but is satisfactory when properly applied. To make a butt weld, it is not necessary to prepare the stock beforehand, although the pieces should have practically the desired shape. The weld is effected by a plunger having a pointed end which is forced through the forward member to be joined, thus closely pressing together the material and insuring a solid weld (see illustration).



This method of welding is not considered as practicable as pin-welding, but when property handled, it is satisfactory for many classes of work. Wrought iron is welded in a forging machine without using any flux but the parts to be joined must be clean and free from scale. As a rule, compressed air is used to remove the scale formed by oxidization. A small jet of air is directed against the work just before the machine is operated. For welding steel having a comparatively high carbon content, it is necessary to use a flux to make a satisfactory weld. (See *Fluxes for Welding*.)

Welding with Thermit

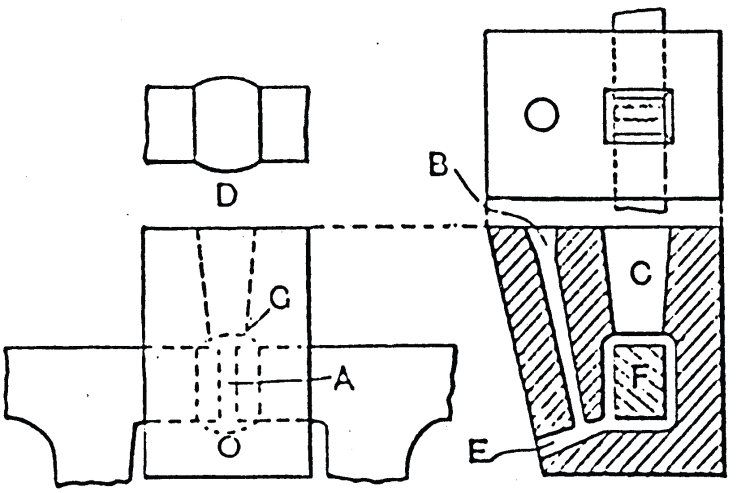
Thermit Process.—This process of welding metals is effected by pouring superheated thermit steel around the parts to be united. Thermit is a mixture of finely divided aluminium and iron oxide. This mixture is placed in a crucible and the steel is produced by igniting the thermit in one spot by means of a special powder, which generates the intense heat necessary to start the chemical reaction. When the reaction is once started it continues throughout the entire mass, the oxygen of the iron being taken up by the aluminum (which has a strong affinity for it), producing aluminum oxide (or slag) and superheated thermit steel. ordinarily, the reaction requires from 35 seconds to one minute, depending upon the amount of thermit used. As soon as it ceases, the steel sinks to the bottom of the crucible and is tapped into a mold surrounding the parts to be welded. As the temperature of the steel is about 5400 degrees F., it fuses and amalgamates with the broken sections, thus forming a homogeneous weld.

www.EngineeringEBooksPdf.com

It is necessary to pre-heat the sections to be welded before pouring, to prevent chilling the steel. The principal steps of the welding operation are, to clean the sections to be welded, remove enough metal at the fracture to provide for a free flow of thermit steel, align the broken members and surround them with a mold to retain the steel, pre-heat by means of a gasoline torch to prevent chilling the steel, ignite the thermit and tap the molten steel into the mold. This process is especially applicable to the welding of large sections. It has been extensively used for welding locomotive frames, broken motor casings, rudder- and stern-posts of ships, crankshafts, spokes of driving wheels, connecting rods, and heavy repair work in general. One of the great advantages of the thermit process is that broken parts can usually be welded in place. For example, locomotive frames are welded by simply removing parts that would interfere with the application of a suitable mold. Thermit is also used for pipe welding, rail welding, and in foundry practice, to prevent the "piping" of ingots.

Preparation of Part to be Welded.— The first step in the operation of thermit welding is to clean the fractured parts and cut away enough metal to insure an manufactured flow of the molten thermit. The oxy-acetylene or oxy-hydrogen cutting torch is very efficient for this operation. The amount that should be cut away depends upon the size of the work. Assuming that a locomotive frame is to be welded, the space should be about $\frac{3}{4}$ inch wide for a small frame, and 1 inch wide for a large frame. The frame sections are then jacked apart about $\frac{1}{4}$ inch to allow for contraction of the weld when cooling; trammel marks are scribed on each side of the fracture to show the normal length. If the weld is to be made on one member of a double-bar frame, the other parallel member should be heated with a torch to equalize the expansion in both sections and prevent unequal strains.

Mold for Thermit Welding.— The mold surrounding the fractured part should be so arranged that the molten thermit will run through a gate to the lowest part of the mold and rise through and around the parts to be welded into a large riser. The accompanying illustration shows a mold applied to a locomotive frame that is broken between the pedestals at *A*. The thermit steel is poured through gate *B*, and rises into space *C* after passing around and between the ends of frame *F*. The mold must allow for a reinforcing band or collar of thermit steel to be cast around the ends to be welded. Space *G*, for forming this collar, and the opening between the frame ends, must be filled before ramming up the mold. Yellow wax is ordinarily used for this purpose. The shape of this band or collar should be as indicated by the view of the completed weld at *D*. The thickest part is directly over the fracture and the band overlaps the edges of the fracture at least one inch.



For a frame of average size, the collars are made about 4 inches wide and 1 inch thick at the center, the thickness being increased for comparatively large sections. An opening is also made at *E* for pre-heating the ends to be welded.

www.EngineeringEBooksPdf.com

Patterns for the riser, pouring and heating gates can be made of wood. The riser *C* should be quite large because the steel that first enters the mold is chilled somewhat by coming into contact with the metal, even when pre-heated. This chilling effect is overcome by using enough thermit steel to force the chilled portion up into the riser and replacing it by metal which has practically the full temperature received during reaction. The mold must be made of a refractory material, owing to the intense heat. The best material is made of one part fire sand, one part fire-clay and one part ground firebrick, thoroughly mixed while dry and moistened just enough to pack well. If these ingredients cannot be obtained, one part fire-clay and one part clean, dry sand may be used. When the mold and box are filled and tamped. the wooden runner and riser patterns are withdrawn. The mold is then ready for the pre-heating and drying operation which causes the wax matrix to melt and run out.

Thermit Required for Welding.—The quantity of thermit required for making a weld can be determined from the cubic contents of the weld. Calculate the cubic contents of the weld and its reinforcement in cubic inclines; double this amount to allow for filling the gate and riser, and multiply by 0.56 to get the number of pounds of thermit required. When wax is used for filling, the weight of the thermit can be determined as follows: Weigh the wax supply before and after filling the fracture. The difference in weight in pounds, or the quantity used, multiplied by 32 will give the weight of thermit in pounds.

Thermit Additions.—When a quantity of more than 10 pounds of thermit is to be used, add 10 per cent of steel punchings (not over ½ inch in diameter) or steel scrap, free from grease, into the thermit powder. If the thermit exceeds 50 pounds, 15 per cent of small mild steel rivets may be mixed with it. One per cent (by weight) of pure manganese and 1 per cent of nickel - thermit should be added to increase the strength of the thermit steel.

Pre-heating — Making a Weld.—The ends to be welded should be red hot at the moment the thermit steel is tapped into the mold. This pre-heating is done, preferably, by a gasoline, compressed-air torch, and, as previously mentioned, it melts the wax matrix used for filling the fracture to form the pattern for the reinforcing band. When the ends have been heated red, quickly remove the torch and plug the pre-heating hole *E* with a dry sand core, backing it up with a few shovelfuls of sand, well packed. The end of the cone-shaped crucible should be directly over the pouring gate and not more than 4 inches above it. To start the reaction, place one-half teaspoonful of ignition powder on top of the thermit and ignite with a storm match. It is important that sufficient time be allowed for the completion of the thermit reaction and for fusion of the steel punchings which have been mixed within the thermit. Within charges containing from 30 to 50 pounds of thermit, the crucible should not be tapped in less than 35 seconds; with charges containing from 50 to 75 pounds, 40 seconds; 75 to 100 pounds, 50 seconds to one minute.

When welding a frame broken as shown in the illustration previously referred to, the screw jack used for forcing the pedestals apart should be turned back somewhat to release the pressure gradually as the weld cools. After pouring, the mold should remain in place as long as possible (preferably 10 or 12 hours) to anneal the steel in the weld, and, in any case, it should not be disturbed for at least two hours after pouring.

When welding a broken spoke in a driving wheel, or a similar part, it is necessary to preheat the adjacent spokes in order to prevent undue strains due to expansion and contraction. If a section of a spoke is broken out, it can be cast in, but if the space is over 6 inches long, it is better to insert a piece of steel and make a weld at each end. Owing to the high temperature 5400 degrees F.) and the violent ebullition of thermit during reaction, the crucible must be lined with a very refractory material. The crucibles used for this purpose have a sheet-iron shell and are lined with magnesia.

Filling Shrinkage Holes and Surface Flaws.—The filling of surface flaws in castings and forgings usually requires from 2 to 10 pounds of thermit. To make a weld of this kind, place an open mold around the part to be filled, large enough to overlap it about ½ inch. Clean the hole thoroughly and heat to a red heat by means of a strong blow-torch. Use eigh-

www.EngineeringEBooksPdf.com

teen ounces of thermit for each cubic inch of space to be filled, but do not use less than two pounds for any one weld. Place a small amount of thermit in the crucible which, in this case, is of a small size for hand use. Ignite the thermit with ignition powder and as soon as it begins to burn, add the remainder, feeding it fast enough to keep the combustion going. When the reaction is completed, quickly pour the slag (which is about three-fourths of the total liquid) into dry sand; then pour the steel into the open mold and sprinkle loose thermit on top to prolong the reaction, as the casting, even when pre-heated, will have a chilling effect on the steel.

Composition of Thermit Steel.— An average analysis of thermit steel is as follows: carbon, 0.05 to 0.10 per cent; manganese, 0.08 to 0.10 per cent; silicon, 0.09 to 0.20 per cent; sulphur, 0.03 to 0.04 per cent; phosphorus, 0.04 to 0.05 per cent; aluminum, 0.07 to 0.18 per cent. The tensile strength is about 65,000 pounds per square inch.

High- and Low-pressure Torches.— The difference between high- and low-pressure welding and cutting torches, according to the generally accepted meaning of the term, is in the pressure of the acetylene. The first oxy-acetylene torches developed by Fouche were of the high-pressure type, using acetylene dissolved in acetone. Later, he developed a low-pressure torch, working on the injector principle, acetylene being drawn into the carburetor chamber where it mixed with the oxygen. The high pressures originally employed in the first torches could not be safely employed with the acetylene produced in generators, because the safe pressure of acetylene in volume should never exceed from 15 to 20 pounds per square inch, and the pressure is limited to 25 pounds per square inch by the Underwriters' Association in the United States: hence, the medium pressure which is in general use was developed. The proportion of oxygen to acetylene varies somewhat in the different torches. Usually from 1.04 to 1.12 times more oxygen is consumed than acetylene.

Welders and cutters should be provided with goggles or spectacles fitted with approved colored lenses that protect the eye from destructive light rays, flying sparks and globules of molten metal.

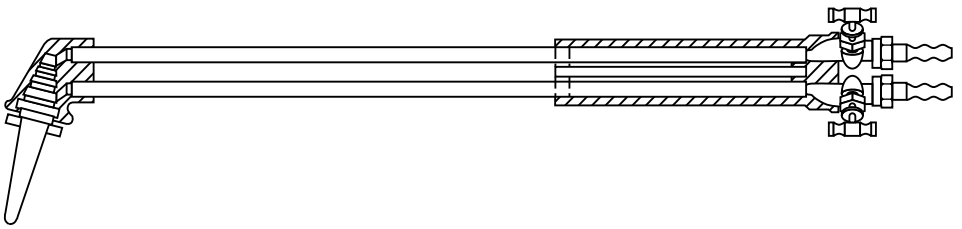
Autogenous or Gas Welding

Autogenous welding is usually defined as a process of uniting metals by fusing them together without compression or hammering and also without using a flux or adding new material to form the joint. When using a high-temperature gas flame, such as is obtained with an oxy-acetylene torch, additional material (in the form of a rod or wire) is ordinarily fused between the parts to be welded and a flux may also be used; hence, the term "autogenous welding" which has been commonly used to designate this method, is not strictly accurate and for this reason the expression "gas welding" is also used to indicate the welding of metals by means of a high-temperature gas flame.

Many different metals can be welded with an oxy-acetylene torch, although in the practical application of this method it is essential to distinguish between classes of work that can be welded on a commercial basis and work which should be done only to meet an emergency and which, under ordinary conditions, might be done more cheaply by other methods.

Welding Torch.— The intense local heat required for welding metal by the gas process is obtained by the combustion of a mixture of gases such as oxygen and acetylene or oxygen and hydrogen.

www.EngineeringEBooksPdf.com



The arrangement of a Davis-Bournonville oxy-acetylene torch, suitable for medium and heavy welding, is shown by the accompanying illustration. This torch is a simple device, consisting of a handle, two needle valves, a tube for the oxygen and another tube for the acetylene, a head and a tip. The upper tube is connected with the oxygen supply and the lower one with the acetylene supply. The acetylene is admitted under lower pressure than the oxygen, and regulators on the storage tanks serve to control the working pressure of both gases. The mixing of the acetylene and oxygen gases takes place in the head of the torch, where the oxygen, flowing longitudinally, meets the cross currents of the acetylene gas flowing in through the holes in the sides. The diameter of the holes in the tip and the pressures of the respective gases determine the quality of the mixture. The diameters of the holes are graded and the tips are numbered to correspond. Those tips are interchangeable, different sizes being required for various classes of work.

Adjusting the Torch.—Before using the welding torch, it is essential to regulate the acetylene and oxygen gas pressures with reference to the thickness of metal to be welded. The accompanying table (compiled by Davis-Bournonville Co.) gives the tip number, the range of metal thicknesses for which it is suited, the acetylene and oxygen pressures and the approximate gas consumption in cubic feet per hour. When using gases from acetylene and oxygen cylinders, it is customary to increase the working pressures slightly above those given in the table, when starting to weld, in order to compensate for the loss of pressure as the gases are used from the cylinders.

The following general instructions for regulating the pressures and adjusting the flame are given by the Davis-Bournonville Co.: First, identify the oxygen and acetylene hose and their respective valves and regulators. Next, open the oxygen needle valve in the torch handle; then, open the oxygen cylinder valve very slowly. Adjust the oxygen gas regulator to obtain a working pressure suitable for the thickness of metal (see table). Close the oxygen needle valve and open the acetylene needle valve. Then, open the acetylene cylinder valve slowly. Adjust the gas regulator to obtain the required working pressure, and light the gas quickly with a "spark lighter."

Obtaining a Neutral Flame: The oxygen and acetylene must now be adjusted to obtain a *neutral flame,* which will neither oxidize (burn) the metal nor carbonize it. When a white cone appears at the tip and beyond the cone there is a white envelope of flame with a long blue streamer flame, the combustion is unbalanced. There is insufficient oxygen and an excess of carbon in the flame. Now, if the oxygen needle valve is opened full, the white-hot cone at the tip will be very short and surrounded by a blue-white envelope. Combustion is now unbalanced because of the excess of oxygen, which combines with all of the acetylene gas available while the remainder tends to attack the metal. Combustion is accompanied by a roaring sound, and the flame is oxidizing. If the oxygen valve is closed slightly until combustion in the flame is balanced, two distinct cones will become visible. The one next to the tip is white hot and beyond is a long blue cone, which is also very hot. The sound differs from that of the carbonizing and oxidizing flames. This is the neutral flame which should be used.

[a] Gas consumption per hour is the maximum with torch burning continuously.

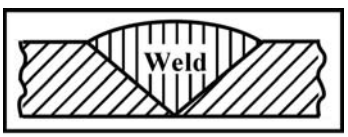
Davis-Bournonville Style C welding torches with Style 99 and 100 tips.

Operators frequently adjust the pressure regulators from one to two pounds above the figures given in the table to allow for gage variations and drop for pressure when the gases are supplied in cylinders.

Temperatures.—The temperature of the oxy-hydrogen flame is estimated to be about 4000 degrees F., and the temperature of the oxy-acetylene flame is estimated to be about 5400 degrees F. by some authorities and as high as 6300 degrees F. by others. The exact temperatures are not known. With the oxy-acetylene flame the number of British thermal units per cubic foot is approximately five times greater than is obtained with the oxy-hydrogen flame.

Size of Torch Tip to Use.—The proper size of tip to use for welding depends upon the thickness of metal and the rate at which the heat is dissipated. Sometimes the rate of conduction and radiation is affected by the location of the parts to be welded. The tip sizes given in the accompanying table represent conservative practice, and welders are advised to use as large a tip as possible without overheating the metal, in order to weld faster and use less gas. If the flame is too small for the thickness of the metal to be welded, the heat will be radiated too rapidly.

Preparing Joint for Welding.—When material is only about 1/16 to 1/8 inch thick, it can be welded successfully when the edges are square, but when thicker plates are to be welded, it is necessary to bevel the edges to obtain the best results, as otherwise the heat of the flame suitable for welding will not penetrate and cause perfect fusion beyond a depth of, say, from 1/8 to 3/16 inch; hence, when material is thicker than about 1/8 inch, the edges are beveled and the V-shaped channel thus formed is filled by using adding material. The edges of steel and iron plate should be beveled to an angle of 45 degrees, so that when the plates are placed together, the included angle of the V-shaped channel is about 90 degrees. (See accompanying illustration.)



The angle may be smaller for brass and bronze when the work is done by experienced men. If the plates are quite thick, it is preferable to bevel and weld on both sides, the bevel extending into the center of the plate from each side. When it is necessary to weld thick material from one side only, it is advisable to reduce the included angle to about 60 degrees. Aluminum need not be beveled as much as steel, and if the plates are 1/4 inch thick or less, beveling is not necessary when a welding iron or spud is employed to break up the oxide, although experience is required to work successfully in this manner.

www.EngineeringEBooksPdf.com

Provision for Expansion and Contraction.—As a general rule, 1 or 2 per cent of the length of the weld is allowed for expansion and contraction when welding two plates of steel together, especially if the weld is long. For example, if the joint is 12 inches long, the pieces should be laid so that they are ¼ inch farther apart at one end than at the end where the welding is begun; thus, there is a tapering space between them. After the parts are "tacked" together and as the welding proceeds, the molten metal cools and contracts. This contraction causes the welded section to act like a hinge, and the unwelded ends draw closer together. It is often difficult to provide for expansion and contraction when welding castings.

Welding Rods or Adding Materials.—Mild steel should be welded with a welding rod or wire that is low in carbon. A welding rod having the composition of pure Swedish iron is preferable. The use of commercial steel wire is not recommended. Cast-iron welding rods should be made from a fine grade of cast iron, high in silicon and low in manganese and sulphur. The best rods are cast in metal molds, which insure density of metal and freedom from blow-holes and sand. Cast aluminum welding rods are used on aluminum castings and the drawn rods or wire are preferable for welding rolled aluminum sheets. Brass and bronze are welded with cast welding rods and drawn bronze rods. Brass wire is not suitable as it contains too much zinc which burns out, leaving the welding material defective. The diameter of the rod or wire should be chosen with reference to the thickness of the joint and the size of the tip and flame. A small wire should not be used for welding a heavy plate.

General Procedure when Welding.—To become proficient in the art of autogenous welding requires experience and practice, but a knowledge of some of the fundamental principles will enable the operator to make more rapid progress. It is advisable to begin by welding thin strips of iron or steel not over ⅛ inch in thickness. Such light metals can be welded without the addition of a filling-in material. The torch should be given a semicircular or zig-zag motion. This movement tends to blend the metal and reduces the liability of overheating. The beveled surfaces of thicker materials are heated by a semicircular movement of the flame, care being taken to melt them to a soft, plastic state without burning the metal. Wherever fusion occurs, new metal should be added from a "welding rod," the composition of which is suitable for the work in hand. The surface should be thoroughly fused before adding metal from the welding stick, and the latter should be held close to, or in contact with, the puddle of molten metal. The heat is then radiated from the puddle to the welding rod, whereas if the metal were allowed to drop through the flame, it might be burned to an injurious extent.

Pre-heating Castings.—As a general rule, it is necessary to pre-heat all cast-iron parts before welding, although some parts of very simple form may be welded without pre-heating. The source of heat for pre-heating depends upon local conditions and the character of work. Oil burners, charcoal fires, or pre-heating stoves using oil or gas are used. A hardwood charcoal fire is sometimes used in preference to oil blow-torches. All pre-heated parts should be covered with asbestos paper as much as possible during pre-heating and welding, and the welded section should be immediately protected from radiation and rapid cooling after welding.

Welding Cast Iron.—It is highly important to pre-heat all cast iron before welding except possibly very simple parts, as explained in the preceding paragraph. The metal should be covered as soon as the weld is finished and be allowed to cool slowly. If the metal is more than ¼ inch thick, the edges should be beveled at an angle of about 45 degrees on each side. For comparatively heavy welds, it is well to leave three small points of contact for aligning the broken parts in their original position. To make the weld, the flame should be passed for some distance around the fracture and then be directed on it until the metal is cherry-red. When this occurs, have an assistant throw on a little scaling powder, and when the metal begins to run, add cast iron from the cast-iron "welding stick," which should be of specially refined material. Powder should be added only when the metal does not flow well, as little

www.EngineeringEBooksPdf.com

as possible being used. Never attempt to re-weld pieces that have been previously welded or brazed, without first cutting away all of the old metal.

Welding Steel.—Steel less than $\frac{1}{8}$ inch thick can be welded without the addition of any welding metal. If the thickness exceeds $\frac{1}{8}$ inch, the edges should be beveled or chamfered. It is very important not to add the welding material until the edges are fused or molten at the place where the weld is being made. In no case should the flame be held at one point until a foam is produced, as this is an indication that the metal is being burned. Do not hold the flame steadily in the center of the weld, but give it a semicircular or zig-zag motion with an uplifting movement at each revolution, the object being to drive the molten metal toward the center of the weld. When welding a crack located in the middle of a heavy steel sheet, begin by chamfering the metal on each side of the fracture at an angle of 45 degrees, the slope extending to the bottom; then apply the welding torch to the sheet beyond the end of the crack, until there is sufficient expansion to open the crack perceptibly. The weld should then be made, and, as a rule, it will be found that the expansion will compensate for the contraction when cooling. No flux is required when welding low-carbon steel, because the oxide melts at a lower temperature than the fusing point of the metal. Flux may be used on the higher carbon steels to prevent oxidation.

Aluminum Welding.—The successful welding of aluminum alloy castings by the oxy-acetylene process, depends a great deal upon the success achieved in breaking down the aluminum oxide, the forming of which is intensified as soon as the oxy-acetylene torch flame comes in contact with the metal. It is this oxide film that prevents the proper flow of the metal at the welding temperatures and that has been the cause of many failures in aluminum welds.

Cleaning Surfaces: The surfaces to be joined must be thoroughly cleaned and the material near the surfaces to be welded must also be clean, as otherwise the impurities near the joint will invariably set up auto-corrosion in the weld. Oily machine parts should be allowed to remain for a few seconds in a hot 10 per cent caustic soda solution, after which, the castings should be thoroughly washed and scrubbed in plenty of clean hot water. It is often advisable first to wash the oily castings with gasoline to remove the greater part of the grease and dirt.

Joint Beveling: After the work is cleaned, a V-shaped groove is filed or chipped along the crack or seam to the bottom to permit the metal to be melted the full depth of the work. However, aluminum alloy castings up to $\frac{1}{4}$ inch in thickness can be welded with the torch flame without beveling the joints.

Preheating: In welding aluminum and aluminum alloy castings, it is necessary to preheat and anneal the work in order to prevent too rapid expansion and contraction of the metal. Preheating also conserves gas, increases the rate of welding, and prevents warping. Great care, however, must be exercised to avoid exceeding a temperature of 750 and 840 degrees F., respectively, when preheating and reheating or annealing the work. At higher temperatures a piece of work may be rendered useless by deformation. During the preheating of castings of complex shape or castings that vary greatly in thickness, the casting should be covered with sheet asbestos to keep the temperature as uniform as possible. The asbestos should not be removed during the welding operation, except as it is necessary to effect the weld.

Welding Procedure: A puddling rod, made from a piece of mild steel rod $\frac{3}{16}$ or $\frac{1}{4}$ inch in diameter and flattened on one end like a flat scraper, is used in welding to scrape and agitate the metal at the moment of melting in order to break up the oxide and allow the molten metal to flow together. It is necessary to wipe the puddling rod frequently to prevent it from becoming coated with oxide, and care must be taken not to allow it to reach a red heat, as otherwise oxide of iron will be formed on it which might result in a defective weld. The oxide formed in the course of melting aluminum offers considerable resistance to the weld-

www.EngineeringEBooksPdf.com

ing flame, and it must be eliminated to effect a homogeneous weld. This is best done by employing an aluminum alloy welding flux which dissolves and deoxidizes the layer of oxide adjacent to the joint to be welded, at the temperature at which the aluminum reaches a molten state.

The welding material, usually a rod or broken aluminum part, should be of as pure aluminum as it is possible to obtain and the end of the rod should be kept in the molten bath while welding. For aluminum alloy castings, the welding material should be of approximately the same composition as the alloy to be welded.

Flame Adjustment: In making a weld, the torch flame should be so adjusted that it will furnish a slight excess of acetylene, and it is essential to avoid contact of the white-hot bulb or cone with the metal that is about to become molten, because the hot temperature in this part of the flame tends to produce holes in the metal which are often difficult to repair. The correct distance varies according to the size of torch tip employed, but in general, the distance should be from ¼ to ¾ inch. After welding, the casting should be reheated evenly and allowed to cool very slowly. When the casting is cold, it should be thoroughly washed in hot water to remove all traces of the flux, which would otherwise continue to produce a chemical action on the metal that would result in harmful corrosion.

Aluminum Welding Fluxes.—The oxide formed in the course of melting aluminum offers considerable resistance to the welding flame. It does not always rise to the surface, especially if the work is thick, yet it must be eliminated to effect a homogeneous weld. This is done by employing a flux which dissolves and deoxidizes the layer of oxide adjacent to the joint to be welded, at the temperature at which the aluminum reaches a molten state. Another function of a flux is to protect the fused metal from contact with the air.

An example of a good flux for aluminum and aluminum alloys with a melting point of approximately 1110 degrees F. is one containing a mixture of lithium chloride, potassium chloride, potassium bisulphate, and potassium fluoride.

When castings that have sand on their surface are to be welded, a flux that will remove the sand must be used. If the sand is not removed, it is in part reduced, resulting in silicon being passed into the metal — a condition that often reduces the strength of the weld an appreciable amount. A flux that is adapted for use under these conditions is composed of potassium chloride or fluorspar. This flux will prevent silicon from entering the alloy.

The flux may be applied in paste form to the surfaces to be welded, or the parts may be heated and the powdered flux sprinkled over the joint, or the end of the welding rod may be heated and dipped into the flux, which readily adheres to it in the form of a thin varnish; the last method is the safest and best.

Welding Brass.—In many cases it is preferable to braze rather than to weld brass parts. When the oxy-acetylene torch is used for brass, adjust the flame until there is a single cone, as for steel welding. Keep the point of the white flame slightly away from the weld, according to the thickness of the piece, so that the heat will not be sufficient to burn the copper in the brass or volatilize the zinc. If a white smoke appears, remove the flame, as this indicates excessive heat. A little borax should be used as a flux. For brass welding, it is advisable to use a tip about one size larger than for the same thickness of steel. As the weld is really cast brass, it will not have the strength of rolled sheet brass. Do not breathe the fumes while welding brass.

Welding Copper.—The purest copper wire obtainable should be used as a filler when welding copper and great care should be taken to prevent oxidation. Use the same kind of flame as for steel, but a much larger tip for corresponding dimensions, because of the great radiating property of copper. Pre-heating is necessary when a large piece of copper is to be welded, as otherwise so much heat from the torch will be dissipated by radiation that little will be left for fusing the metal. Copper will weld at about 1930 degrees F.; hence, the flame need not have so high a temperature as for steel and it must not be concentrated on so small a surface. On account of the radiation, however, the total quantity of heat must be

www.EngineeringEBooksPdf.com

greater. Welded copper has the strength of cast copper, but can be rendered more tenacious by hammering. The radiation of heat from copper can be considerably lessened by covering it with asbestos sheets while heating. To weld copper to steel, first raise the steel to a white heat (the welding point); then put the copper into contact with it and the two metals will fuse together. When the copper begins to flow, withdraw the flame slightly to prevent burning. Ordinary borax may be used as a flux for copper welding.

Welding High-speed Steel to Machine Steel.—Compression welding can be employed advantageously for welding small high-speed drills which require carbon steel shanks of special length. A jig made to hold the carbon steel shank and the high-speed steel drill in line should be employed, and the ends set about ⅛ inch apart. When the ends have been heated by the torch to the welding temperature, or until the ends are in a pasty condition, the drill is given a smart rap with a wooden mallet and driven against the steel shank, thus producing a butt or compression weld. This method is most successful for lengthening small twist drills with the oxy-acetylene torch.

Welding Cast Iron to Steel.—To weld cast iron to steel, cast-iron rods are used as welding material. The steel must be first heated to the melting point, as cast iron melts at a lower temperature. A very little scaling powder should be used. Pre-heating the cast iron and steel is generally recommended when the joint exceeds three of four inches in length, especially if adjacent parts are thin and likely to crack.

Welding Steel Castings.—As steel castings vary in carbon content, no fixed rule can be laid down for welding them; but, in general, they offer no serious difficulty to welding provided approved welding rods are used. This statement applies to castings whose carbon content is not more than 0.25 per cent. Steel castings containing carbon much in excess of 0.25 or 0.30 per cent may require the use of special welding rods such as those containing nickel. Nickel welding rods give good results on certain grades of steel castings, railway track steel, switch points and other steel products having comparatively high carbon content.

Welding Malleable Iron.—Welding of malleable iron with the oxy-acetylene torch is not recommended, the reason being that the welded joint is necessarily weaker than the malleable iron due to the changes in physical structure produced by the high temperature. Brazing with an approved bronze rod is recommended. A brazed joint in malleable iron will generally be nearly, if not quite, as strong as the original material. Brazing can be effected at a temperature that causes little change in the malleable characteristics.

Welding Tool Steel.—Welding tool steel of the higher carbon contents, with the oxy-acetylene torch, is not generally recommended. The carbon content is changed and the weld produced may be valueless for tool purposes. However, a skilled welder can produce welds in high-carbon steel under proper conditions with fair success and if properly heat-treated they may give satisfaction under some conditions of use.

Welding Alloy Steels.—The alloy steels such as vanadium, chrome-nickel, etc., used in motor car construction may be welded successfully with adding material containing vanadium or nickel. The welds should be heat-treated afterwards in order to restore the joint portion to the physical condition of the part before welding.

Hard-Facing

Hard-facing is the process of welding on to parts or surfaces a coating, edge or point of a metal highly capable of resisting abrasion and wear. In other words, a metal surface, which, due to its use, may normally be worn away rapidly is protected by a layer of special alloy. The process can be applied equally well to new parts or to old worn parts. In many instances, if hard-facing is employed, the metal for the part itself can be selected primarily to withstand shock and fatigue without regard to wear resistance. This often effects a considerable saving in the first cost of the part.

www.EngineeringEBooksPdf.com

Hard-Facing Materials.—Hard-facing materials may be divided into three general classes: The first comprises alloys having an iron base and containing such elements as chromium, tungsten, manganese, silicon and sometimes cobalt and nickel. The second class is composed of non-ferrous alloys, and the third class consists of the so-called diamond substitutes which are essentially tungsten carbide.

Hard-facing materials of the first class are generally used only under conditions of moderate abrasive wear or severe impact. This class is represented by Hascrome, a self-hardening chromium-manganese-iron alloy. Deposits of Hascrome have a tensile strength of 40,000 and a compressive strength of 177,000 pounds per square inch. Deposits made by the oxy-acetylene process have a hardness of 240 to 500 Brinell, depending upon the amount of excess acetylene in the flame and upon the rate of cooling. Slow cooling makes Hascrome harder than does quenching. Arc-welded deposits have a hardness of 240 to 400 Brinell, depending on the rate of cooling. Hascrome has the property of work hardening under impact, a property similar to that of manganese steel.

The second class (non-ferrous alloys) is represented by Haynes Stellite. This cobalt-chromium-tungsten alloy combines excellent welding properties with maximum wear resistance. When cold, Haynes Stellite is almost as hard as hardened steel and it has the unique property of retaining its original hardness practically unimpaired at the high surface heats developed by friction — and even at a red heat. Haynes Stellite welding rod is available in different grades which vary in regard to physical properties such as hardness, abrasion resistance, shock resistance, etc. All possess to a marked degree the quality of red hardness which is so essential in a wear-resistant alloy.

In the third class (diamond substitutes). Haystellite, a cast tungsten carbide, is recommended. It approaches the diamond in hardness but posesses considerable toughness. It cannot be applied, like welding rods, by melting with the oxy-acetylene flame. It is, therefore, used in the form of small castings of uniform size and shape which are held in place by a binding material. Composite rod consists of various screen sizes of sharp, irregular-shaped grains of Haystellite uniformly distributed in a binding material. These rods are applied quickly and easily with the oxy-acetylene flame like ordinary hard-facing materials.

Soldering and Brazing

Solders.—Solders for joining metallic surfaces or edges are almost invariably composed of an alloy of two or more metals. The solder used must have a lower melting point than the metals to be joined by it, but the fusing point should approach, as nearly as possible, that of the metals to be joined so that a more tenacious joint is effected. Solders may be divided into two general classes, hard and soft. The former fuses at a red head; the latter, at a comparatively low temperature. These solders are also subdivided into a variety of classes such as brass, silver, gold, copper, tin, plumbers' solder and others — the name, in most cases, designating the application.

Soft Solders.—Soft solders consist chiefly of lead and tin, although other metals are occasionally added to lower the melting point. Lead-tin alloys melt at a lower temperature, with an increase in the percentage of tin, up to a certain point, but when the tin exceeds 67 per cent, the melting point rises gradually to the melting point of tin, as shown by the table “Melting Temperatures of Lead-tin Alloys.” This table also gives the Brinell hardness test. The results show that the hardest alloy contains 66 per cent of tin and 34 per cent of lead. Soft solders are termed “common,” “medium” and “fine,” according to the tin content, those containing the most lead being the cheapest and having the highest melting temperatures.

Fine solder is largely used for soldering britannia metal, brass and tin-plate articles. It is also used for soldering cast iron, steel, copper and many alloys. The soft solder called “common” is used by plumbers for ordinary work; this solder contains two parts of lead to one part of tin. The best soft solders are made from pure lead and pure tin. Antimony is an

www.EngineeringEBooksPdf.com

objectionable impurity as it renders the solder less fluid when melted and tends to prevent perfect adhesion of the surfaces. Zinc also has an injurious effect on soft solder, causing it to flow sluggishly. Aluminum acts in a similar way. A small percentage of phosphorus renders soft solder very "lively"; that is, the solder has a tendency to run freely. Too much phosphorus is injurious, and if added to thin the solder it should be in the form of phosphor-tin. One or two ounces of five per cent phosphor-tin to one hundred pounds of solder is generally sufficient.

Melting Temperatures of Lead-tin Alloys

Percentage		Melting Temp., Deg. F.	Brinell Hardness Test	Percentage		Melting Temp., Deg. F.	Brinell Hardness Test

Hard Soldering and Brazing.—Hard solder is used for joining such metals as copper, silver and gold, and alloys such as brass, German silver, gun metal, etc., which require a strong joint and often a solder the color of which is near that of the metal to be joined. The hard soldering of copper, iron, brass, etc., is generally known as brazing, and the solder as spelter. The operations of hard soldering and brazing are identical, and the two terms are often used interchangeably. According to common usage, however, there is the following distinction. Brazing is generally understood to mean the joining of metals by a film of brass, whereas hard soldering (which is the term used by jewelers) ordinarily means that "silver solder" is used as the uniting medium. (See *Silver Solders* on page 3259). For hard soldering or brazing, a red heat is necessary, and borax is used as a flux to protect the metal from oxidation, and to dissolve the oxides formed. Heating cannot be done with a soldering iron, but should be effected by a blowpipe, blowtorch, gas forge or a coke or charcoal fire.

As a greater degree of heat is required to melt spelter than soft solder, brazed work will withstand more heat without breaking or weakening than parts which are soldered. The chief advantage of a brazed joint, however, lies in its superior strength. Before work is assembled for brazing, it should be carefully cleaned; the parts are then fastened together in the position they are to occupy when joined. Usually the pieces are secured by pinning, but sometimes wire, bolts or clamps are used for holding the parts together. If practicable, they should be secured in such a way that the work can be turned over during the process of brazing without disturbing the relation of the parts, thus affording a better chance to apply the flux and spelter.

Composition of Brazing Alloys

Fluxes for Soldering.— As two pieces to be soldered must be thoroughly alloyed with the material used as a solder, the temperature must be raised and maintained at such a point that inter-penetration can take place completely. It is necessary that the surfaces to be joined be perfectly clean, and means must be provided to prevent oxidation during soldering, oxides tending to prevent interfusion. This is accomplished by using a coating of some substance that melts at the fusing temperature of the solder, and thus excludes the air. The coating should have a solvent action on the oxide, thus keeping the metal clean and enabling the metal and solder to unite thoroughly. The fluxes generally used are rosin, sal-ammoniac, zinc chloride and borax. The flux is added first and the solder melted by means of a flame or soldering iron, the latter first having been smoothed with a file and then properly tinned. Rosin and chloride of zinc are fluxes commonly used for soft soldering tin (tinned iron)

www.EngineeringEBooksPdf.com

brass, etc. For hard soldering or brazing, use burnt or calcined borax, or boracic acid in powdered form. In all cases where zinc chloride is used as a flux, the article should be cleaned after soldering to prevent subsequent corrosion of the metal.

Alloys for Brazing Solders.—The alloys or "spelters" used for brazing are composed of copper-zinc alloys. The melting point of these alloys depends upon the percentage of zinc. As the proportion of zinc increases, the melting point is lowered, as shown by the table *Melting Temperatures of Copper-zinc Alloys* on page 3257. The fusing point of the spelter should be as close as possible to that of the article to be brazed, as a more tenacious joint is thereby secured. An easily fusible spelter may be made of two parts zinc to one part copper, but the joint will be weaker than when an alloy more difficult to fuse is employed. A spelter that is readily fused may be made of 44 per cent copper, 50 per cent zinc, 4 per cent tin and 2 per cent lead. Alloys containing much lead should be avoided, since lead does not transfuse with brass and thus decreases the strength of the joint. A hard solder for the richer alloys of copper and zinc may be produced from 53 parts copper and 47 parts zinc. Copper and iron have a much higher melting point than brass, thus allowing the use of a richer copper alloy. Tin is often added as one of the ingredients, but it should be sparingly used, because it increases the brittleness of the solder. The addition of tin to brass lightens the color, giving it a gray tint. A variety of different brazing alloys and their characteristics are given in the table *Composition of Brazing Alloys* on page 3257.

Silver Solders.—Silver solder is a hard solder containing silver, copper and zinc or brass. The composition of silver solders varies considerably according to the nature of the work. A silver solder extensively used by jewelers contains 70 parts silver and 30 parts copper. Silver coins can be used for small work. Silver soldering is employed for uniting comparatively small parts requiring a strong joint. The heating is usually effected by a blowpipe, and borax or powdered boracic acid may be used as a flux. The flux should be applied before heating, if possible.

A hard solder of low fusing point, that is used extensively by one of the largest electrical companies, is composed of 34.36 per cent copper; 49.24 per cent silver; and 16.40 per cent zinc. Borax is used as a flux.

Solders for German silver are generally made of the same materials as those which compose the alloy to be soldered, but in such proportions that the melting point is lower. In some cases, silver solder is used for uniting German silver articles, and German silver solder is also used for soldering articles of iron and steel on account of its high melting point and tenacity. German silver solder is known under different names, as argentan, arguzoid, etc. It is rendered moderately fusible by an addition of zinc to the copper and nickel. If the solder is too brittle, this is an indication of too much zinc, which defect can be remedied by adding the requisite amount of copper and nickel. For soldering alloys composed of from 16 to 22 per cent; nickel, the following proportions may be used as a solder: Copper 47 per cent; nickel 11 per cent; and zinc 42 per cent.

Dip Brazing.—The principal difference between "dip brazing" and ordinary brazing is that with the former method the work is immersed into the molten spelter until the parts are heated sufficiently to be united by it. This method is extensively employed in bicycle manufacture as it is more economical for duplicate work.

Brazing Band-saws.—Band-saws are joined by lap brazing, silver solder being generally used. The lap is formed by beveling the ends to a sharp edge for a length of about $\frac{3}{8}$ inch for saws up to $\frac{3}{4}$ inch wide, and $\frac{1}{2}$ inch for saws from $\frac{3}{4}$ to $1\frac{1}{2}$ inch wide. After a flux (such as borax) has been applied to the joint, the ends are clamped together. The solder is sometimes melted into the joint from the edges, or it may be applied between the two surfaces. A convenient method is as follows: Pound a piece of silver, about the size of a dime, until quite thin; then clamp it between the surfaces to be brazed after applying damp, powdered borax. When the heat is applied and the silver melts, clamp the beveled ends of the saw

www.EngineeringEBooksPdf.com

tightly together. The heating should be localized as much as possible. For a flux, use lump borax and pulverize it as used.

Cleaning Surfaces to be Brazed.—Before brazing iron or steel, the surfaces should be thoroughly cleaned, either by filing, grinding or by the use of a sand blast. Brass or bronze parts can be cleaned by dipping in a solution of one-third nitric acid and two-thirds sulphuric acid. This same solution can be used to remove the scale after brazing.

Aluminum Solder.—A thoroughly reliable aluminum solder that is used by a large electrical concern is composed of 75.5 parts (by weight) of tin; 18 parts of zinc; and 2.5 parts of aluminum. No flux is needed. It is advisable to slightly heat the parts to be soldered. Another aluminum solder is composed of 80 per cent tin and 20 per cent zinc, stearic acid being used as a flux.

Sweating.—When parts are soldered together by heating them sufficiently to melt the solder, instead of using a soldering iron, the operation is often known as sweating. Brass boxes for engine connecting-rods are usually sweated together prior to machining, in order to hold the two halves in alignment while finishing the sides and boring. The finished surfaces forming the joint between the brasses are first tinned or covered with solder. This is done by heating the brasses enough to melt the solder, then applying a flux (such as sal-ammoniac), and finally the solder. After tinning, the brasses are again heated if the solder has hardened; they are then put together and allowed to cool. The halves are separated after machining by heating them until the solder melts.

Brazing High-speed Steel Tips to Carbon Steel Shanks.—A method which is used in a large manufacturing plant is as follows: A seat is formed in the tool shank to receive the tip. A welding compound or flux is used in welding the tip to the shank. The flux is placed on the seat of the shank and the tip is then put on top of the flux in the desired position. The tool is placed in the preheating chamber of the furnace and heated to 1550 – 1660 degrees F., allowing sufficient time for complete penetration of the heat. The tool is then removed from the preheating chamber and the tip is pressed firmly to the seat of the shank to insure a close contact between the two pieces. Then the tool is placed in the main furnace chamber and heated rapidly to a temperature of approximately 2250 to 2400 degrees F., depending upon the kind of material used for the tip and its hardening requirements. The tool is next removed from the furnace and sufficient pressure applied to the tip to insure perfect cohesion. The press used for this purpose should be equipped with a pivoted pressure shoe and this shoe must be preheated to prevent cracking of the tip.

The hardening is accomplished at the same time as the tipping operation when tools are tipped with low-cobalt high-speed and high-cobalt high-speed steel. Tools that cannot be ground after hardening are often heated in barium chloride or some similar salt bath. After the pressing and welding operation, the tool is cooled to room temperature under an air blast or quenched in oil. It is advisable to maintain the oil quenching bath at a temperature of 150 to 200 degrees F. After the tipping operation, the tool should be reheated uniformly in an open furnace to a temperature of 1050 to 1150 degrees F, and allowed to cool in air. The hardened tools should have a minimum Rockwell C hardness of 63. Tips are cut from bar stock according to dimensions on standard detail drawing. The material generally used for the shanks of tools tipped with the cutting materials regularly employed contains 0.50 to 0.63 per cent carbon; 0.60 to 0.90 per cent manganese; 0.04 per cent phosphorus; and 0.15 per cent silicon.

Brazing Carbide Tips to Steel Shanks.—Sintered carbide tips or blanks are attached to steel shanks by brazing. Shanks usually are made of low-alloy steels having carbon contents ranging from 0.40 to 0.60 per cent.

www.EngineeringEBooksPdf.com

One Prominent manufacturer of carbide tools recommends the following shank steels in the order listed: 1) High-silicon steel containing approximately 0.55 carbon, 0.85 manganese, 0.30 vanadium, 2.10 silicon, 0.25 chromium, and maximum sulphur and phosphorus contents of 0.025; 2) S.A.E. 2340 steel; and 3) any low-alloy steel having 0.40 to 0.60 carbon.

Shank Preparation: The carbide tip usually is inserted into a milled recess or seat, but some prefer to omit the recess and braze the tip to the top of the shank. When a recess is used, the bottom should be flat to provide a firm even support for the tip. The corner radius of the seat should preferably be somewhat smaller than the radius on the tip to avoid contact and insure support along each side of the recess.

Cleaning: All surfaces to be brazed must be absolutely clean. Surfaces of the tip may be cleaned by grinding lightly or by sand-blasting. Cleaning with carbon tetrachloride is also recommended.

Brazing Materials and Equipment: The brazing metal may be copper, naval brass such as Tobin bronze, or silver solder. A flux such as borax is used to protect the clean surfaces and prevent oxidation. Heating may be done either in a furnace or by means of an oxy-acetylene torch or an oxy-hydrogen torch. Copper brazing usually is done in a furnace, although an oxy-hydrogen torch with excess hydrogen is sometimes used. An oxy-acetylene torch usually is employed for silver brazing or soldering.

Brazing Procedure: One method of brazing with a torch is to first place a thin sheet material, such as copper foil, around and beneath the carbide tip, the top of which is covered with flux. The flame is applied to the under side of the tool shank, and, when the materials melt, the tip is pressed firmly into its seat with tongs or with the end of a rod. If the brazing material is in the form of wire or rod, this may be used to coat or tin the surfaces of the recess after the flux melts and runs freely. The tip is then inserted, flux is applied to the top, and the heating is continued until the coatings melt and run freely. A firm which supplies carbide tips with nickel-coated surfaces ready for silver soldering, suggests the following procedure: The tip, after coating with flux, is placed in the recess and the shank end is heated. Then a small piece of silver solder, having a melting point of 1325 degrees F., is placed on top of the tip. When this solder melts, it runs over the nickel-coated surfaces while the tip is held firmly into its seat. In all carbide tip brazing, the brazed tool should be cooled slowly to avoid cracking due to unequal contraction between the steel and carbide. To insure slow cooling, the tool may be buried in powdered charcoal, graphite, asbestos, mica, or lime.

Braze Hardening.—This copper-brazing method is applicable in tipping lathe, planer or similar tools with molybdenum steel tips. First clean the tip and end of the shank by immersion in carbon tetrachloride. Cover end of shank with commercial powdered copper brazing flux; then insert the tool partly in the muffle of the furnace (electric or gas). When the flux melts, withdraw the tool and place the tip in position with the copper sheet or foil below and also above the tip. Add more flux and preheat the tip to about 1500 degrees F. Then move the tip end in and heat the tool uniformly to the full hardening temperature; then withdraw it from the furnace and force out the excess copper or flux either with tongs or a press. When the copper solidifies, quench the tip end in oil to below 200 degrees F. This operation, which usually requires less than twenty minutes, brazes and hardens the tip. The final step is to temper the tipped tool at 1050 degrees F.

Previously hardened high-speed steel tips may be attached to shanks by silver brazing. It is possible to braze the hardened tip and temper it simultaneously. This braze-tempering method is suitable for tools not subject to heavy roughing cuts. Tools which are braze-hardened, may be used for either roughing or finishing cuts because copper will withstand much higher temperatures than silver solder; moreover, the tool shank is hardened considerably by the braze-hardening method, whereas, in braze tempering, the shank is relatively unhardened.

Coloring Metals

General Requirements in the Coloring of Metal Surfaces.—Copper is more susceptible to coloring processes and materials than any of the other metals, and hence the alloys containing large percentages of copper are readily given various shades of yellow, brown, red, blue, purple, and black. Alloys with smaller percentages of copper (or none at all) can be given various colors, but not as easily as if copper were the principal ingredient, and the higher the copper content, the more readily can the alloy be colored. The shades, and even the colors, can be altered by varying the density of the solution, its temperature and the length of time the object is immersed. They can also be altered by finishing the work in different ways. If a cotton buff is used, one shade will be produced; a scratch brush will produce another, etc. Thus to color work the same shade as that of a former lot, all the data in connection with these operations must be preserved so they can be repeated with exactness.

Cleaning Metals for Coloring.—Metal surfaces to be colored chemically must first be thoroughly cleaned. To remove grease from small parts, dip in benzine, ether or some other solvent for the grease. Boil large pieces in a solution of one part caustic soda and ten parts water. For zinc, tin or britannia metal, do not use caustic soda, but a bath composed of one part carbonate of soda or potash and ten parts water. After boiling, wash in clean water. Do not touch the clean surfaces with the fingers, but handle the objects by the use of tongs or wires.

Pickling Solutions or Dips for Coloring.—The grease removal should be followed by chemical cleansing, which principally serves the purpose of removing the greenish or brownish films which form on copper, brass, bronze, etc. The composition of the bath or mixture for pickling varies for different metals. For copper and its alloys, a mixture of 100 parts concentrated sulphuric acid (66 degrees Baume and 75 parts nitric acid (40 degrees Baume is sometimes used. If the metal is to be given a luster instead of a mat or dull finish, add about 1 part common salt to 100 parts of the pickling solution, by weight. A better dip for a mat surface consists of 90 parts nitric acid (36 degrees Baume 45 parts concentrated sulphuric acid, 1 part salt, and from 1 to 5 parts of sulphate of zinc, by weight. The composition of copper-zinc alloys will produce different color tones in the same dip and will affect the results of chemical coloring. After pickling, washing in water is necessary.

Another good method of removing these films is to soak the work in a pickle composed of spent aquafortis until a black scale is formed, and then dip it for a few minutes into a solution of 64 parts water, 64 parts commercial sulphuric acid, 32 parts aquafortis, and 1 part hydrochloric acid. After that the work should be thoroughly rinsed several times with distilled water.

Coloring Brass.—Polished brass pieces can be given various shades from golden yellow to orange by immersing them for a certain length of time in a solution composed of 5 parts, by weight, of caustic soda, 50 parts water and 10 parts copper carbonate. When the desired shade is reached, the work must be well washed with water and dried in sawdust. Golden yellow may be produced as follows: Dissolve 100 grains lead acetate in 1 pint of water and add a solution of sodium hydrate until the precipitate which first forms is re-dissolved; then add 300 grains red potassium ferro-cyanide. With the solution at ordinary temperatures, the work will assume a golden yellow, but heating the solution darkens the color, until at 125 degrees F. it has changed to a brown.

To Produce a Rich Gold Color.—Brass can be given a rich gold color by boiling it in a solution composed of 2 parts, by weight, of saltpeter, 1 part common salt, 1 part alum, 24 parts water and 1 part hydrochloric acid. Another method is to apply a mixture of 3 parts alum, 6 parts saltpeter, 3 parts sulphate of zinc, and 3 parts common salt. After applying this mixture the work is heated over a hot plate until it becomes black, after which it is washed with water, rubbed with vinegar, and again washed and dried.

www.EngineeringEBooksPdf.com

White Colors or Coatings.—The white color or coating that is given to such brass articles as pins, hooks and eyes, buttons, etc., can be produced by dipping them in a solution made as follows: Dissolve 2 ounces fine-grain silver in nitric acid, then add 1 gallon distilled water, and put this into a strong solution of sodium chloride. The silver will precipitate in the form of chloride, and must be washed until all traces of the acid are removed. Testing the last rinse water with litmus paper will show when the acid has disappeared; then mix this chloride of silver with an equal amount of potassium bitartrate (cream of tartar), and add enough water to give it the consistency of cream. The work is then immersed in this solution and stirred around until properly coated, after which it is rinsed in hot water and dried in sawdust.

Silvering.—A solution for silvering, that is applicable to such work as gage or clock dials, etc., can be made by grinding together in a mortar 1 ounce of very dry chloride of silver, 2 ounces cream of tartar, and 3 ounces common salt, then add enough water to obtain the desired consistency and rub it onto the work with a soft cloth. This will give brass or bronze surfaces a dead-white thin silver coating, but it will tarnish and wear if not given a coat of lacquer. The ordinary silver lacquers that can be applied cold are the best. Before adding the water, the mixture, as it leaves the mortar, can be kept a long time if put in very dark colored bottles, but if left in the light it will decompose.

To Give Brass a Green Tint.—One solution that will produce the Verde antique, or rust green, is composed of 3 ounces crystallized chloride of iron, 1 pound ammonium chloride, 8 ounces verdigris, 10 ounces common salt, 4 ounces potassium bitartrate and 1 gallon of water. If the objects to be colored are large, the solution can be put on with a brush. Several applications may be required to give the desired depth of color. Small work should be immersed and the length of time it remains in the solution will govern the intensity of the color. After immersion, stippling the surface with a soft round brush, dampened with the solution, will give it the variegated appearance of the naturally aged brass or bronze.

Blackening Brass.—There are many different processes and solutions for blackening brass. Trioxide of arsenic, white arsenic or arsenious acid are different names for the chemical that is most commonly used. It is the cheapest chemical for producing black on brass, copper, nickel, German silver, etc., but has a tendency to fade, especially if not properly applied, although a coat of lacquer will preserve it a long time. A good black can be produced by immersing the work in a solution composed of 2 ounces white arsenic, 5 ounces cyanide of potassium, and 1 gallon of water. This should be boiled in an enamel or agate vessel, and used hot. Another cheap solution is composed of 8 ounces of sugar of lead, 8 ounces hyposulphite of soda and 1 gallon of water. This must also be used hot and the work afterwards lacquered to prevent fading. When immersed, the brass first turns yellow, then blue and then black, the latter being a deposit of sulphide of lead.

Preservation of Color.—After a part has been given the desired color, it is usually washed in water and then dried with clean sawdust. The colored surfaces of alloys are commonly protected and preserved by coating with a colorless lacquer, such as japan lacquer. Small parts are coated by dipping, and large ones by rubbing the lacquer on. The lacquer is hard after drying, and insoluble in most fluids; hence, it can be washed without injury.

Niter Process of Bluing Steel.—The niter process of bluing iron and steel is as follows: The niter or nitrate of potash (often called saltpeter) is melted in an iron pot and heated to about 600 degrees F. The parts to be blued are cleaned and polished and then immersed in the molten niter until a uniform color of the desired shade has been obtained. This requires only a few seconds. The articles are then removed and allowed to cool, after which the adhering niter is washed off in water. Parts which will not warp may be immersed immediately after removing from the niter bath. After cleaning, dry in sawdust, and then apply some suitable oil, such as linseed, to prevent rusting. To secure uniform coloring, a pyrometer should be used to gage the temperature of the niter, because a higher heat than 600 degrees F. will produce a dark color, whereas a lower heat will give a lighter shade.

www.EngineeringEBooksPdf.com

Bluing Steel by Heat-treatment.— Polished steel parts can be given a blue color by heating in hot sand, wood ashes, or pulverized charcoal. Place the substance in an iron receptacle and stir constantly, while heating, in order to heat uniformly. Heat just hot enough to char a pine stick. The parts to be blued must be absolutely free from grease. They are placed in the heated substance until the desired color is obtained. Further coloring is then checked by immersing in oil. Small parts are sometimes heated by a Bunsen burner or by laying upon a heated plate. For a light blue color, heat in sand or wood ashes, and for a dark blue, use pulverized charcoal. The quality of the color depends largely upon the fineness of the finish. Still another method of coloring by heat is to immerse the parts in a molten bath of potassium nitrate and sodium nitrate. The coloring is then checked by plunging the work into boiling water.

Blue-black Finish.— To obtain a blue-black finish on small steel parts, use a mixture of 16 parts, by weight, of saltpeter and 2 parts of black oxide of manganese. This mixture is heated to a temperature of 750 degrees F. and the objects are immersed in it. The oxide of manganese is deposited on the work and must, therefore, be frequently replenished in the mixture.

Black Finish.— To obtain a black rust-protecting finish on hardened parts, temper, after hardening, in "heavy" cylinder oil; then immediately place the part with the oil on it in an oven having a temperature of from 300 to 350 degrees F. Remove the work in from 5 to 8 minutes, when the black finish is baked onto it.

Gun Metal Finish.— Several different chemical solutions have been used successfully for giving steel a gun metal finish or black color. Among these are the following:

1) Bismuth chloride, one part; copper chloride, one part; mercury chloride, two parts; hydrochloric acid, six parts; and water, fifty parts.

2) Ferric chloride, one part; alcohol, eight parts; and water, eight parts.

3) Copper sulphate, two parts; hydrochloric acid, three parts; nitric acid, seven parts; and perchloride of iron, eighty-eight parts.

Other solutions have been prepared from nitric ether, nitric acid, copper sulphate, iron chloride, alcohol and water and from nitric acid, copper sulphate, iron chloride and water. The method of applying these and finishing the work is practically the same in all cases.

The surface is given a very thin coating with a soft brush or sponge that has been well squeezed, and is then allowed to dry. The work is then put in a closed retort to which steam is admitted and maintained at a temperature of about 100 degrees F., until the parts are covered with a slight rust. They are then boiled in clean water for about fifteen minutes and allowed to dry. A coating of black oxide will cover the surface, and this is scratch brushed. After brushing, the surface will show a grayish black. By repeating the sponging, steaming and brushing operations several times, a shiny black lasting surface will be obtained. For the best finishes, these operations are repeated as many as eight times.

Another process employs a solution of mercury chloride and ammonium chloride which is applied to the work three times and dried each time. A solution of copper sulphate, ferric chloride, nitric acid, alcohol and water is then applied three times and dried as before. A third solution of ferrous chloride, nitric acid and water is applied three times, and the work is boiled in clean water and dried each time. Finally, a solution of potassium chloride is applied and the work boiled and dried three times. The work is then scratch brushed and given a thin coating of oil. Ordnance for the French Government is treated in this way. The above methods are applicable to hardened and tempered steels, as a temperature of 100 degrees F. does not affect the hardness of the steel. For steels that will stand 600 degrees temperature without losing the desired hardness, better and much cheaper methods have been devised.

The American Gas Furnace Co. has developed a process employing a furnace with a revolving retort. The work is charged in this, together with well-burnt bone. A chemical solution that gasifies when it enters the furnace is then injected into this retort while the

www.EngineeringEBooksPdf.com

work is heated to the proper temperature. This solution has been named "Carbonia." The color does not form a coating on the outside, as with the other processes, but a thin layer of the metal itself is turned to the proper color. By varying the temperature of the furnace, the time the work is in it, and the chemical, different colors can be produced from light straw to brown, blue, purple and black, or gun metal finish. Rough or sand-blasted surfaces will have a frosted appearance, while smooth polished surfaces will have a shiny brilliant appearance.

Browning Iron and Steel.— A good brown color can be obtained as follows: Coat the steel with ammonia and dry it in a warm place; then coat it with muriatic or nitric acid and dry it in a warm place; then place the steel in a solution of tannin or gallic acid and again dry it. The color can be deepened by placing the work near the fire, but it should be withdrawn the minute the desired shade is reached or it will turn black.

To Produce a Bronze Color.— A bronze-like color can be produced by exposing iron or steel parts to the vapors of heated aquaregia, dipping them in melted petroleum jelly, and then heating them until it begins to decompose, when it is wiped off with a soft cloth. Another method of producing this bronze-brown color is to slightly heat the work, evenly cover the surfaces with a paste of antimony chloride (known as "bronzing salt"), and let the object stand until the desired color is obtained. The paste can be made more active by adding a little nitric acid.

To Produce a Gray Color.— A gray color on steel can be obtained by immersing the work in a heated solution of ten grains of antimony chloride, ten grains of gallic acid, 400 grains of ferric chloride and five fluid ounces of water. The first color to appear is pale blue, and this passes through the darker blues to the purple, and, finally, to the gray. If immersed long enough, the metal will assume the gray color, but any of the intermediate colors may be produced. When used cold, this is also one of the bronzing solutions.

Mottled Coloring.— Mottled colors on steel can be produced by heating the objects to a good cherry-red for several minutes in cyanide of potassium, then pouring the cyanide off, and placing the receptacle containing the work back on the tire for five minutes. The contents are then quickly dumped into clean water. To heighten the colors, boil afterward in water and oil.

Coppering Solution.— A coppering solution for coating finished surfaces in order that lay-out lines may be more easily seen, is composed of the following ingredients: To 4 ounces of distilled water (or rain water) add all the copper sulphate (blue vitriol) it will dissolve; then add 10 drops of sulphuric acid. Test by applying to a piece of steel, and, if necessary, add four or five drops of acid. The surface to be coppered should be polished and free from grease. Apply the solution with clean waste, and, if a bright copper coating is not obtained, add a few more drops of the solution; then scour the surface with fine emery cloth, and apply rapidly a small quantity of fresh solution.

White Coatings for Laying Out Lines.— Powdered chalk or whiting mixed with alcohol is commonly used for coating finished metal surfaces preparatory to laying out lines for machining operations. Alcohol is preferable to water, because it will dry quicker and does not tend to rust the surface. This mixture can be applied with a brush and is more convenient than a coppering solution for general work. For many purposes, the surface can be coated satisfactorily by simply rubbing dry chalk over it.

To Produce Gray Colors.— A solution of 1 ounce of arsenic chloride in 1 pint of water will produce a gray color on brass, but if the work is left in this solution too long it will become black. The brass objects are left in the bath until they have assumed the correct shade, and are then washed in clean warm water, dried in sawdust and finally in warm air.

Blue and Violet Shades.— To give brass a blue color, dissolve 1 ounce of antimony chloride in 20 ounces of water, and add 3 ounces hydrochloric acid; then warm the work and immerse it in this solution, until the desired blue is obtained After that wash in clean water and dry in sawdust. A permanent and beautiful blue-black can be obtained by using just

www.EngineeringEBooksPdf.com

enough water to dissolve 2 ounces copper sulphate and then adding enough ammonia to neutralize and make it slightly alkaline. The work must be heated before immersion.

To Give Brass a Green Tint.—One solution that will produce the Verde antique, or rust green, is composed of 3 ounces crystallized chloride of iron, 1 pound ammonium chloride, 8 ounces verdigris, 10 ounces common salt, 4 ounces potassium bitartrate and 1 gallon of water. If the objects to be colored are large, the solution can be put on with a brush. Several applications may be required to give the desired depth of color. Small work should be immersed and the length of time it remains in the solution will govern the intensity of the color. After immersion, stippling the surface with a soft round brush, dampened with the solution, will give it the variegated appearance of the naturally aged brass or bronze.

Chromium Plating.—Chromium plating is an electrolytic process of depositing chromium on metals either as a protection against corrosion or to increase the surface wearing qualities. The value of chromium-plating plug and ring gages has probably been more thoroughly demonstrated than any other one application of this treatment. Chromium-plated gages not only wear longer, but when worn, the chromium may be removed and the gage replated and reground to size.

In general, chromium-plated tools have operated well, giving greatly improved performance on nearly all classes of materials, such as brass, bronze, copper, nickel, aluminum, cast iron, steel, plastics, asbestos compositions, and similar materials. Increased cutting life has been obtained with chromium-plated drills, taps, reamers, files, broaches, tool tips, saws, thread chasers, and the like, Dies for stamping, drawing, hot-forging, die-casting, and for molding plastic materials have shown greatly increased life after being plated with hard chromium.

Special care is essential in grinding and lapping tools preparatory to plating the cutting edges, because the chromium deposit is influenced materially by the grain structure and hardness of the base metal. The thickness of the plating may vary from 0.0001 to 0.001 or 0.002 inch, the thicker platings being used to build up undersize tools such as taps and reamers.

Procedure followed by Westinghouse in the hard chromiurn-plating of tools, as well as parts salvaged by depositing chromium to increase diameters, is as follows: 1) Degrease with solvent; 2) mount the tools on racks; 3) clean in an anodic alkali bath held at a temperature of 82-degrees C. for from three to five minutes; 4) rinse in boiling water; 5) immerse in a 20 per cent hydro-chloric acid solution for two to three seconds; 6) rinse in cold water; 7) rinse in hot water; 8) etch in a reverse-current chromic acid bath for two to five minutes; 9) place work immediately in the chromium-plating bath; and 10) remove hydrogen embrittlement, if necessary, by immersing the plated tools for two hours in an oil bath maintained at 177 degrees C.

Chromium has a very low coefficient of friction. The static coefficient of friction for steel on chromium-plated steel is 0.17, and the sliding coefficient of friction is 0.16. This compares with static coefficient of friction for steel on steel of 0.30 and a sliding coefficient of friction of 0.20. The static coefficient of friction for steel on babbitt is 0.25, and the sliding coefficient of friction 0.20, whereas for chromium-plated steel on babbitt, the static coefficient of friction is 0.15, and the sliding coefficient of friction 0.13. These figures apply to highly polished bearing surfaces. Articles that are to be chromium-plated in order to resist frictional wear should be highly polished before plating so that full advantage can be taken of the low coefficient of friction that is characteristic of chromium. Chromium resists attack by almost all organic and inorganic compounds, except muriatic and sulphuric acids. The melting point of chromium is 29.30 degrees F., and it remains bright up to 1200 degrees F. Above this temperature, it forms a light adherent oxide, which does not readily become detached. For this reason, chromium has been used successfully for protecting articles that must resist high temperatures, even above 2000 degrees F.

www.EngineeringEBooksPdf.com

Bronzing.—Bronzing is a process by means of which a bronze-colored surface is produced on objects made from other metals or from wood, plaster, or other materials. A bronze-like color can be produced by exposing iron or steel parts to the vapors of heated *aqua regia,* then dipping them in melted vaseline, and finally heating them until the vaseline begins to decompose, when they are wiped off with a soft cloth. Bronze-like colors may also be produced by slightly heating the work, covering the surface with a paste of antimony chloride, also known as "bronzing salt," and letting the object stand until the desired color is obtained. The paste of bronzing salt may be made more active by adding a small quantity of nitric acid. Bronze colors can also generally be produced on metals by the action of dilute nitric acid and sal-ammoniac. The so-called "antique bronze" appearance is produced by painting over the bright metal with a solution of sal-ammoniac, cream of tartar, silver nitrate, and common salt. Plaster and wood are bronzed by first coating the articles with a sizing and then covering them with a bronze powder produced by powdering brass or bronze.

Etching And Etching Fluids

Etching Fluids for Different Metals.—A common method of etching names or simple designs upon steel is to apply a thin, even coating of beeswax or some similar substance which will resist acid; then mark the required lines or letters in the wax with a sharp-pointed scriber, thus exposing the steel (where the wax has been removed by the scriber point) to the action of an acid, which is finally applied. To apply a very thin coating of beeswax, place the latter in a silk cloth, warm the piece to be etched, and rub the pad over it. Regular coach varnish is also used instead of wax, as a "resist."

An etching fluid ordinarily used for carbon steel consists of nitric acid, 1 part; water, 4 parts. It may be necessary to vary the amount of water, as the exact proportion depends upon the carbon in the steel and whether it is hard or soft. For hard steel, use nitric acid, 2 parts; acetic acid, 1 part. For high-speed steel, nickel or brass, use nitro-hydrochloric acid (nitric, 1 part; hydrochloric, 4 parts). For high-speed steel it is sometimes better to add a little more nitric acid. For etching bronze, use nitric acid, 100 parts; muriatic acid, parts. For brass, nitric acid, 16 parts; water, 160 parts; dissolve 6 parts potassium chlorate in 100 parts of water; then mix the two solutions and apply.

A fluid which may be used either for producing a frosted effect or for deep etching (depending upon the time it is allowed to act) is composed of 1 ounce sulphate of copper (blue vitriol); ¼ ounce alum; ½ teaspoonful of salt; 1 gill of vinegar, and 20 drops of nitric acid. For aluminum, use a solution composed of alcohol, 4 ounces; acetic acid, 6 ounces; antimony chloride, 4 ounces; water, 40 ounces.

The National Twist Drill Co. employs the following method for etching on cutters and other tools: The steel is brushed with asphaltum varnish which is allowed to stand until it thickens and hardens to the right degree; then the desired inscription is pressed through the asphaltum with a rubber stamp and the etching fluid (nitrohydrochloric acid or *aquaregia*) is applied with a medicine dropper. Practice and experience are required to judge just when the varnish has dried to the right consistency. A similar method, which has been successfully used for etching names on cutlery, is to coat the surface with gum guaiacum varnish. A rubber stamp having the name or design is then coated with a thin layer of potash solution. When this stamp is applied to the work, the varnish is "cut" by the potash wherever the coated stamp comes into contact with it; the surface is then brushed lightly with water to remove the loosened varnish and expose the lettering or design, which is then etched by applying dilute nitric acid. The rubber-stamp method is a very cheap and rapid process. One method of applying the potash is to press the stamp against a pad soaked with the solution. The action of etching fluids on steels varies somewhat according to the composition, high-carbon and alloy steels being acted upon more slowly than low-carbon steel or wrought iron.

www.EngineeringEBooksPdf.com

Etching Brass Nameplates.—Etched brass nameplates having a black background are now often used in preference to cast plates, as they are less expensive. The etched plate is produced by coating a flat and polished sheet of brass with a thin layer of bichromated albumen, and exposing it to the light for a few minutes under a glass negative upon which are a number of the desired nameplate designs. (In order to prepare the bichromated albumen, mix together 10 parts of the white of egg with 30 parts of water. A second mixture is then made consisting of 2 parts of potassium bichromate and 58 parts of water. The first mixture composed of the white of egg and water, and the second mixture containing potassium bichromate and water, are next mixed together in a dark room. The bichromated albumen thus obtained should be kept and used in the dark.) When the brass plate is developed, this removes the albumen not exposed to the light (or that which has been protected by the black portions of the negative), and leaves the brass free to be etched. The etching solution will not attack the parts protected by the albumen or "resist."

The etching is done by a solution of perchlorate of iron, or by making the plate the anode in an acid-copper solution. When the plate has been etched to the required depth, it is washed. If the etched surface is tarnished, as it usually is after drying, a solution made of 2 parts of water an 1 part of muriatic acid should be spread over the surface to remove the stains and leave it clean and uniform. The plate should then be rinsed, but not dried. Then, without removing the resist, it is treated in some manner to produce a black background. When this has been done, the resist is removed and the sheet is cut up to form the individual nameplates, which are then lacquered.

Producing a Black Background.—The use of a black nickel deposit is the best method of producing a black background on etched brass name-plates. This solution does not affect any of the various kinds of resist used, and a large number of plates can be treated in a tank at one time. The black nickel bath is composed of water, 1 gallon; double-nickel salts, 8 ounces; ammonium sulpho-cyanate, 2 ounces; zinc sulphate, 1 ounce. This solution is used cold, with a weak current of about 1 volt. With a greater voltage, the deposit will be streaked and gray. As soon as the deposit is black, remove the plates, rinse, dry and cut to the desired size; then lacquer immediately in order to prevent the brownish discoloration which will otherwise form on the surface of the deposit. This solution can be used for brass, copper, bronze, etc.

Etching Ornamental Designs in Metal.—When metal plates having an ornamental design are required in small quantities, the etching process is sometimes used. The photographic method which is employed for nearly all intricate designs is as follows: The design is first drawn on white paper to any convenient scale, in black and white. A photographic negative is then made, or this may be procured from photo engravers who make a specialty of such work. The blacks and whites must be, respectively, opaque and transparent. This negative is used to print the design on the work to be etched, the metal, in order to take the design, being coated with a sensitized emulsion of bi-chromated albumen which has the property of remaining insoluble in water after exposure to the light. The portions corresponding to the opaque parts of the negative thus wash out in warm water, leaving the metal bare. Just prior to washing, however, the surface is coated with special lithographic ink, by means of a roller. The design is now on the metal, surrounded by a resist of a bichromated albumen base covered with a sticky ink. This resist is further reinforced by sprinkling the surface with dragon's blood. The latter is melted by heating and adheres to the resist, but forms a powder on the unprotected surface which can readily be blown off. This resist is effective, provided the etching is not done too deeply. For brass and copper, a strong solution of perchloride of iron is generally preferred as an etching fluid, as this does not attack the resist like strong acids, although its action is comparatively slow. Nitric acid may be used with proper resists. While etching is usually employed for cutting into the surface of the metal, the same process can be used for perforating the design in the plate.

Various acid-resisting materials are used for covering the surfaces of steel rules, etc., prior to marking off the lines on a graduating machine. When the graduation lines are fine

www.EngineeringEBooksPdf.com

and very closely spaced, as on machinists' scales which are divided into hundredths or sixty-fourths, it is very important to use a thin resist that will cling to the metal and prevent any under-cutting of the acid; the resist should also enable fine lines to be drawn without tearing or crumbling as the tool passes through it. One resist that has been extensively used is composed of about 50 per cent of asphaltum, 25 per cent of beeswax, and, in addition, a small percentage of Burgundy pitch, black pitch, and turpentine. A thin covering of this resisting material is applied to the clean polished surface to be graduated and, after it is dry, the work is ready for the graduating machine. For some classes of work, paraffin is used for protecting the surface surrounding the graduation lines which are to be etched. The method of application consists in melting the paraffin and raising its temperature high enough so that it will flow freely; then the work is held at a slight angle and the paraffin is poured on its upper surface. The melted paraffin forms a thin protective coating.

Etching Resists.—Various acid-resisting materials are used for covering the surfaces of steel rules, etc., prior to marking off the lines on a graduating machine. When the graduation lines are fine and very closely spaced, as on machinists' scales which are divided into hundredths or sixty-fourths, it is very important to use a thin resist that will cling to the metal and prevent any under-cutting of the acid; the resist should also enable fine lines to be drawn without tearing or crumbling as the tool passes through it. One resist that has been extensively used is composed of about 50 per cent of asphaltum, 25 per cent of beeswax, and, in addition, a small percentage of Burgundy pitch, black pitch, and turpentine. A thin covering of this resisting material is applied to the clean polished surface to be graduated and, after it is dry, the work is ready for the graduating machine. For some classes of work, paraffin is used for protecting the surface surrounding the graduation lines which are to be etched. The method of application consists in melting the paraffin and raising its temperature high enough so that it will flow freely; the work on which the graduating is to be done is held at a slight angle and the paraffin is poured on its upper edge. As the melted paraffin flows across the work surface, the latter will be covered with a thin protective coating.

Burnishing

The burnishing of metals is a method of securing smooth finished surfaces by compressing the outer layer of the metal, either by the application of highly polished tools, or by the use of steel balls which, by rolling contact, produce smooth surfaces.

Burnishing of Spun or Drawn Shapes: After sheet metal is spun, or drawn in presses, the smooth, even surface which it has when it comes from the mills is changed to a rough, uneven surface having high and low spots which are hardly noticeable to the naked eye, but very easily distinguished under the magnifying glass. The working operations distend or elongate the molecules, and the annealing operation restores them to their original shape. Some shells are annealed several times before the burnishing operation is reached, besides being pickled after each annealing to remove the scale; this leaves the surface of the metal in a matted condition, as well as soft and without temper.

A spun shell can be gone over with a planisher, and hardened, but the scale and dirt is crowded into the grain of the metal and the only way to obtain a smooth surface is to buff or cut it down until this pitted face is removed, thus wasting about 10 per cent of the metal. The spinner can do this in another way, that is by skimming or shaving the uneven surface, but even more metal is wasted than by buffing, and the shell is also weakened by gouging the high places. This same shell could be left without polish, and the chuck transferred to the burnishing lathe, which runs at much greater speed than one used for spinning. After the shell is dipped right to remove all spinning dirt and scale, it can then be polished to an even surface, the uneven face of the metal being amalgamated or smoothed down to a bright surface of the proper temper; it is then colored with a cloth buff to obtain a perfect finish. The gage or thickness remains the same, as there is no dirt or scale to buff out. It is necessary to have a metal chuck in burnishing, and where the shell has been spun on such a chuck, the latter can be used for both operations. Some work can be lacquered without col-

www.EngineeringEBooksPdf.com

oring on the buff wheel, the only operation after burnishing being to wash in hot water and dry at once in hot sawdust.

Burnishing Tools: Burnishing tools are made extremely hard and no temper is drawn. These tools have to be re-polished when they become coated with metal, the interval between polishings depending upon the texture of the metal worked and its temper, a shell that has been annealed several times coating the tool more than one that has not. The end of a burnisher may be polished quickly. A board of soft wood is used, or a strip of leather fastened to a board and to the bench, in a position convenient to the operator. Grooves are worn into the leather or board, and flour of emery and oil, or flint flour and water, is used to clean the tools, a few passes of a tool being all that is necessary to polish it.

Cleaning Work for Burnishing: The bright dip which is used to clean work before burnishing is composed of oil of vitriol (sulphuric acid), 2 parts; aqua fortis (nitric acid), 1 part. This solution should be kept in a crock set in a tank of running water, and mixed 7 or 8 hours before using, as the acids when combined heat up. It is best to mix the acids the day before using. In dipping brass, copper, and German silver, the parts are strung on a stiff brass or copper wire whenever possible. If there are no holes in the metal that can be used for stringing, they can be put in a metal or crock basket, but they cannot be handled to good advantage as it is very difficult to thoroughly wash and dip them. The work should be washed in boiling potash, and then dipped in cold water to clean the potash off and cool the metal. After cooling in the water, the parts are dipped for a few seconds in the acids, and are kept constantly in motion, so that the surfaces will he all exposed equally; they are then shaken thoroughly above the acid and immediately washed in two separate cold-water baths, then in hot soapy water, and finally in hot water, after which they are dried at once in hot sawdust. This operation will leave a bright, clean surface free from acid.

Lubricants for Burnishing: Common yellow soap, dissolved to thick paste, may be used as a lubricant when burnishing brass. The shells and the finger pads are dipped in clear water, and the tool is dipped in the soap paste before burnishing each shell. A lubricant for copper is made by dissolving about one ounce of ivory or castile soap in a gallon of water. The shells and pads are dipped in this solution, no lubricant being used on the tool. Yellow soap should not be used on copper, as the action of the resin on copper is different from that on brass, the metal being so glazed or greased that the tool works badly. For copper plate on steel, such as copperized steel oilers, etc., about one-half ounce of oil of vitriol to four gallons of water should be used. The burnishing tool should be dipped in a mixture of mutton tallow that has been melted with 5 per cent of beeswax. and the work and the finger pads should be dipped in the acid mixture. The tool is lubricated in the tallow mixture before burnishing each shell.

For German silver, the shell should be dipped in clear water, the finger pads in sour beer, and the tool in yellow soap paste. For white metal or britannia, use ivory or castile soap in the paste form for the tool, and sour beer or ox gall in water (4 ounces to the gallon) for the finger pads. Wash the work in hot alkali water (a spoonful of cream of tartar, saleratus or soda to a pail of water), and dry in hot sawdust. For burnishing work which is to be lacquered, without coloring on the cloth buff, use thin glue for a lubricant, and also on the finger pads. When the part is burnished, put it in saleratus water to keep it from tarnishing; then wash in hot water and dry in hot sawdust.

Burnishing Broach.—This is a broach having teeth or projections which are rounded on the top instead of being provided with a cutting edge, as in the ordinary type of broach. The teeth are highly polished, the tool being used for broaching bearings and for operations on other classes of work where the metal is relatively soft. The tool compresses the metal, thus making the surface hard and smooth. The amount of metal that can be displaced by a smooth-toothed burnishing broach is about the same as that removed by reaming. Such broaches are primarily intended for use on babbitt, white metal, and brass, but may also be satisfactorily used for producing a glazed surface on cast iron. This type of broach is also used when it is only required to accurately size a hole.

www.EngineeringEBooksPdf.com

Burnishing by Ball Process.—Barrel burnishing is done to finish, polish, or brighten metal parts without cutting away the stock, steel balls acting as individual burnishing tools. Tilting barrels are sometimes used for ball burnishing when the work is small, but the horizontal type is universally recommended. The hardened and polished steel balls roll over the work while under pressure, and rub against the parts evenly. The pressure is caused by the weight of the balls and the work in the barrel. Some manufacturers claim that a horizontal barrel, large in diameter and comparatively small in width, is the best type to use, because a certain quantity of balls will not spread over so large a space, and will therefore create a greater pressure on the work. In this type of barrel, about two pecks of steel balls should be used for one peck of work, and to this should be added a sufficient quantity of soapy water to rise one inch above the contents of the barrel. Soapy water serves as a lubricant. About six ounces of pure soap or soap chips without much alkali should be put in each pail of water. Another manufacturer claims that a barrel of small diameter, and comparatively long, completely filled with work, balls, and soapy water, is more efficient than the type just mentioned. It is said that the work then passes constantly and evenly through the mass of balls without bumping and falling against each other.

Polygon-shaped barrels prevent the work from bunching together and sliding instead of tumbling inside the barrel. Balls from $\frac{1}{16}$ to $\frac{1}{4}$ inch in diameter are generally used, the size depending on the work and dimension of the cavity or corners in the pieces; the balls should be small enough to enter all cavities, and to insure this, a round steel slug with a fin-like edge is sometimes used. Articles to be barrel-burnished must be cleaned and must be free from oil or dirt. Double and triple burnishing barrels permit of burnishing more than one class of work at a time. Burnishing barrels permit the finishing of hundreds and thousands of small pieces at one time quickly and inexpensively.

Burnishing Dies.—When an exceptionally good finish or polish is required, blanks which have been trimmed in a shaving die are pushed through what is known as a *burnishing* die. Such a die has an opening which tapers slightly inward toward the bottom, and it is finished very smooth, so that, when the blank is forced through by the punch, the metal around the edges is compressed and polished. Naturally, the degree of finish on the blanks will depend largely upon the finish of the burnishing surface of the die.

Burnishing Lathes.—A burnishing lathe is smaller than a spinning lathe, and it has only one speed although the speeds of different lathes are varied to suit the work. The counter shaft is fastened to the floor under the lathe; this is necessary on account of the great speed; besides a downward pull of the driving belt causes less vibration than the upward pull of a belt from an overhead countershaft. The burnishing is done by pushing the tool over the work, beginning at the front end and pushing always against the chuck or form over which the work is held. The toolpost is used as a fulcrum and the tool, which is pressed against the work, as a lever. The tool is given a slight rotary motion, and only the thin edge or end is used. While the pressure against the work is not great, the area in contact with the metal is so small, and the speed of the lathe so high, being from 3200 to 5000 revolutions per minute, that the tool leaves a bright surface. The skill of the operator lies in passing the tool over the metal so as to leave a continuous bright surface without any trace of the tool marks; to do this the tool must be fed with regularity and without overlapping or leaving any dull places.

Burnishing Roller.—The roller type of burnishing tool is sometimes used in machine shops, especially railway repair shops, for rolling the cylindrical surface of a journal, crankpin bearing surface, etc., in order to obtain a smooth dense finish. The burnishing tool consists of a hardened roller or disk which is supported by a shank held in the lathe toolpost. The leading edge or side of this disk is rounded and the burnishing is done by feeding the roller over the surface the same as in turning. The roller may be mounted on a plain bearing, but tools of improved design are equipped with roller bearings.

FASTENERS

Distinguishing Bolts From Screws

STEEL SCREWS AND BOLTS are classified in Chapter 73, *Harmonized Tariff Schedule of the United States (HTSUS)* under heading 7318. The tariff has separate provisions for the different types of screws and bolts, and separate provisions for threaded and non-threaded fasteners. The tariff pages covering the various types of steel screws and bolts can be found by checking the latest version of the HTSUS at www.usitc.gov.

U.S. Customs and Border Protection uses fastener industry standards to distinguish bolts from screws. When a fastener is described in a fastener industry dimensional standard as either a screw or a bolt, that standard is followed; otherwise ANSI/ASME B18.2.1-1981, *Specification for Identification of Bolts and Screws*, (the "Specification") provides a well-recognized, comprehensive basis for the common and commercial meaning of bolt and screw as understood by the fastener industry in the United States.

The Specification includes both primary and supplementary criteria. If a fastener does not meet the primary criteria and does not conform to a fastener industry standard for a bolt, then it probably is a screw. The supplementary criteria help distinguish bolts from screws. These rules are subordinate to Customs rulings and court decisions.

Specification.—The following definitions are based on *Specification for Identification of Bolts and Screws*, ANSI/ASME B18.2.1-1981. The specification establishes a recommended procedure for determining the identity of an externally threaded fastener as a bolt or as a screw.

Bolt: A bolt is an externally threaded fastener designed for insertion through the holes in assembled parts, and is normally intended to be tightened or released by torquing a nut.

Screw: A screw is an externally threaded fastener capable of being inserted into holes in assembled parts, of mating with a preformed internal thread or forming its own thread, and of being tightened or released by torquing the head.

Explanatory Data.—A bolt is designed for assembly with a nut. A screw has features in its design that make it capable of being used in a tapped or preformed hole in the work. It is possible to use certain types of screws in combination with a nut. *Any externally threaded fastener which has a majority of the design characteristics which assist its proper use in a tapped or other preformed hole is a screw*, regardless of how it is used in service .

Procedure.—To identify an externally threaded fastener as a bolt or as a screw, two sets of criteria, *Primary* and *Supplementary,* shall be applied. The primary criteria shall be applied first. Any fastener which satisfies one of the primary criteria shall be identified accordingly, and no further examination need be made. The supplementary criteria shall be applied to a fastener which does not satisfy completely any one of the primary criteria. The supplementary criteria detail the principal features in the design of an externally threaded fastener that contribute to its proper use as a screw. A fastener having a majority of these characteristics shall be identified as a screw.

Primary Criteria.—1) An externally threaded fastener, which because of head design or other feature, is prevented from being turned during assembly, and which can be tightened or released only by torquing a nut, is a bolt. *Example:* Round head bolts, track bolts, plow bolts.

2) An externally threaded fastener, which has a thread form which prohibits assembly with a nut having a straight thread of multiple pitch length, is a screw. *Example:* Wood screws, tapping screws.

3) An externally threaded fastener, which must be assembled with a nut to perform its intended service, is a bolt. *Example:* Heavy hex structural bolt.

4) An externally threaded fastener, that must be torqued by its head into a tapped or preformed hole to perform its intended service is a screw. *Example:* Square head set screw.

www.EngineeringEBooksPdf.com

Supplementary Criteria.—When applying the supplementary criteria compare the specification drawing to which the fastener was made to the drawing of an industry standard fastener in order to see if a given tolerance is fine like a screw, or coarse like a bolt.

Underhead Fillet: A screw should have a controlled fillet at the junction of the head with the body. Because of the severe combined torsion and tension stresses at this junction when torquing the head, the minimum limits of the fillet radius should be specified. Because the screw must be capable of being turned through a minimum clearance hole and into an immovable tapped hole, the maximum limits of the fillet radius should be specified to assure solid seating of the head, and to prevent interference at the top of the hole with the junction of head to body. *Example:* An underhead fillet is the concave junction at the head and the shank intersection of a headed fastener.

Head Angularity: The angularity (squareness) of the underhead bearing surface with the shank of a screw should be controlled to minimize eccentric loading in the screw or assembled parts, and to assure complete seating and uniform underhead bearing pressure.

Example: Angularity is the angle between the axes of two surfaces of a fastener.

Bearing Surface: The under head bearing surface of a screw should be smooth and flat to minimize frictional resistance during tightening, to prevent scoring of the surface against which the head is turned, and to produce uniform clamping loads. *Example:* The bearing surface is the supporting or locating surface of a fastener with respect to the part which it fastens (mates). The loading of a fastener is usually through the bearing surface.

Body: The body of a screw should be closely controlled in accuracy of size and roundness. To fit effectively through a minimum clearance hole, the body diameter must have close tolerances, preferably unilateral on the minus side. *Example:* The body of a threaded fastener is the unthreaded portion of the shank.

Shank Straightness: The shank of a screw should be particularly straight to permit ready engagement with the internal thread, to prevent eccentric loading in the fastener or assembled parts, and to minimize interference with the walls of a minimum clearance hole.

Example, Bow or Camber: Bow or camber is the amount that a side of a surface of a fastener deviates from being straight.

Thread Concentricity: The threads of a screw should be concentric with the body axis within close limits to permit assembly into a tapped hole (which usually has a length of thread engagement longer than a nut) without binding of the body against the walls of a minimum clearance hole.

Thread length: Length of thread on a screw must be sufficient to develop the full strength of the fastener in tapped holes in various materials. *Length of complete thread* is defined as the axial length of a thread section having full form at both crest and root but also including a maximum of two pitches at the start of the thread which may have a chamfer or incomplete crests.

Point: A screw should have a chamfered, or other specially prepared point at its end to facilitate entry into the hole and easy start with the internal thread, which may be distant from the top of the hole. The point also protects the first thread, which, if damaged, may gall or scar the internal thread throughout its entire length. *Example:* The point of a fastener is the configuration of the end of the shank of a headed fastener or of each end of a headless fastener.

Length: The length of a screw should be closely toleranced with variance preferably unilateral on the minus side to prevent bottoming in a tapped hole. *Example:* The length of a headed fastener is the distance from the intersection of the largest diameter of the head with the bearing surface to the extreme point, measured in a line parallel to the axis of the fastener. Exceptions: The length of a shoulder screw and a socket head shoulder screw is the length of the shoulder. The length of a headless fastener is the distance from one extreme point to the other, measured in a line parallel to the axis of the fastener.

Fasteners

Stove Bolt.— This bolt has been so named because of its use in stove building. It is made in a number of different forms, either with a round button, or flat countersunk head, the head having a slot for a screwdriver and the threaded end being provided with a square or hexagon nut.

Flattening Test.— This term as applied to tubing refers to a method of testing a section of tubing by flattening it until the inside walls are parallel and separated by a given distance-usually equal to three times the wall thickness for seamless tubes and five times the wall thickness for lap-welded tubes. Boiler tubes subjected to this test should show no cracks or flaws. The flattening test applied to rivets, consists in flattening a rivet head while hot to a diameter equal to $2\frac{1}{2}$ times the diameter of the shank or body of the rivet. Good rivet steel must not crack at the edges of the flattened head.

Rivets, Cold Formed.— In permanently assembling various light parts, it is often possible to greatly reduce the cost and yet secure sufficient strength by cold forming in an assembling die, the rivet or rivets as an integral part of one of the assembled sections. Figs. 1a, 1b, and 1c illustrate how a steel spring is cold riveted to the heavier section. Plain round punches descend and form the rivets by forcing metal down through the holes in the spring (see Fig. 1b); the metal at the edge is then turned back by the die as shown in Fig. 1c, thus completing the riveting at one stroke of the press. In this particular case, about sixty assemblies per minute are obtained.

Embossed Dowels and Hubs: When dowel-pins are required to insure the accurate location of parts relative to each other, small projections or bosses may be formed directly on many die-made products, the projection being an integral part of the work and serving as a dowel-pin. Figure 1d illustrates how the dowel is formed. The method may be described as a partial punching operation, as a punch penetrate about one-half the stock thickness and forces the boss into a pocket in the die which controls the diameter and compresses the metal, thus forming a stronger projection than would be obtained otherwise. The height h of the dowel or boss should not exceed one-half of the dowel diameter d and h should not exceed one-half of the stock thickness t. This is a practical rule which may be applied either to steel or non-ferrous metals, such as brass.

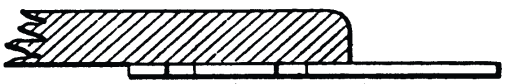

Fig. 1a.

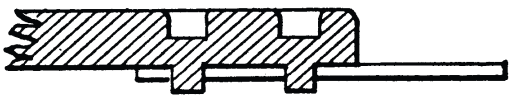

Fig. 1b.

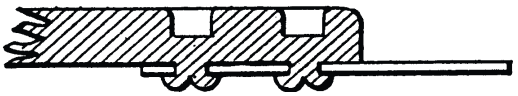

Fig. 1c.

www.EngineeringEBooksPdf.com

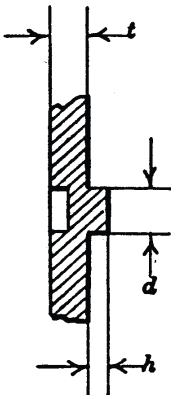

Fig. 1d.

Explosive Rivets.—Explosive rivets are set into metal by means of a special riveting iron which heats the rivet head to about 300 degrees F. and causes detonation of an explosive charge (usually lead azide-tetrazene) in a cavity in the rivet shank. The explosion causes the shank to expand, forming a tight joint between two or more parts.

Expansion Bolt.—When a through bolt cannot be used for attaching a pipe hanger, bracket, or other part, to a wall or ceiling of brick or concrete, what are known as *expansion* bolts are often used. The body of an expansion bolt is divided and the arrangement is such that, when the head of the bolt is turned, the sections forming the body of the bolt are forced outward and against the wall of the hole which has been drilled into the brick, concrete, or stone, as the case may be. Bolts of this type are made in quite a variety of designs. The nominal size represents the diameter of the bolt proper and not the diameter of the casing or expansion member.

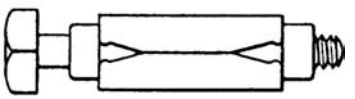

Fig. 2. Expansion Bolt

North Bolt.—A North bolt is one which has a number of longitudinal grooves rolled into its body. This type of bolt is used largely on farming machinery and other agricultural appliances.

Washers.—Plain washers are made in standard sizes to suit standard screw threads, bolts and screws. The manufacturers' regular standard, adopted in 1935, is for bolt sizes ranging from $\frac{1}{4}$ inch up to 3 inches, inclusive. There is also an S.A.E. standard for plain washers. This includes screw and bolt sizes ranging from No. 2 machine screw up to, and including. $1\frac{1}{2}$-inch bolts. These washers are somewhat smaller than the manufacturers' standard and also have smaller inside diameters or clearance spaces between the bolt and washer.

Nut Standardization.—The former American Standard for Nuts, adopted by the American Standards Association in 1933, includes a Regular Series and a Heavy Series. Regular nuts are for general use and the heavy nuts are for applications requiring a larger bearing surface. In each of these series, there are unfinished, semi-finished, and finished grades.

Regular Nuts, Unfinished: The width across the flats of square and hexagon nuts equals $1\frac{1}{2}\times$ screw thread diameter, excepting $\frac{1}{4}$- to $\frac{5}{8}$-inch sizes inclusive, which have widths equal to $1\frac{1}{2}\times$ screw thread diameter + $\frac{1}{16}$ inch, adjusted in all cases to sixteenths. Unfinished nuts are threaded but not machined on any other surface.

Regular Nuts, Semi-Finished: The width across the flats (hexagon nuts only) equals $1\frac{1}{2}\times$ screw thread diameter, excepting sizes $\frac{1}{4}$- to $\frac{5}{8}$-inch inclusive, which have widths equal to

www.EngineeringEBooksPdf.com

1½ × screw thread diameter + 1/16 inch, adjusted in all cases to sixteenths. Semi-finished nuts are threaded and machined on bearing surface only.

Regular Nuts, Finished: The width across the flats equals 1½ × screw thread diameter, excepting ¼ - to ⅝ -inch sizes inclusive, which have widths equal to 1½ × screw thread diameter + 1/16 inch, adjusted in all cases to sixteenths. Finished nuts are threaded and finished on all surfaces. Made in hexagon form only.

Heavy Nuts, Unfinished: The width across the flats of square and hexagon nuts equals 1½ × screw thread diameter + ⅛ inch, adjusted to sixteenths excepting sizes below ½ inch.

Heavy Nuts, Semi-Finished: The width across the flats (hexagon nuts only) equals 1½ × screw thread diameter + ⅛ inch, adjusted to sixteenths, excepting sizes below ½ inch.

Heavy Nuts, Finished: The width across the flats equals 1½ × screw thread diameter + ⅛ inch, adjusted to sixteenths, excepting sizes below ½ inch. Made in hexagon form only.

Wood Screws

The American Standard for wood screws includes both the flat-head and round-head forms. The sizes are indicated by numbers and range from No. 0 to 24. The equivalent diameters range from 0.060 inch to 0.372 inch and are the same as the equivalent diameters for machine screws, although wood screw sizes such as Nos. 11, 14, 16, 18, 20 and 24, are not included in American Standard machine screws. Various forms of wood screws are shown in the illustrations of Tables 1a and 1b. The nominal length of the different forms is indicated by dimensions *L*. As illustrated in Fig. 1k, the length of the roundhead type is from the bottom of the slot; but the nominal length of an American Standard screw is measured under the head. The range of lengths for each screw number is included in the American Standard. The number of lengths for each screw size varies. Commonly used sizes, such as No. 6 to No. 18, are made in twelve to fourteen different lengths, whereas small sizes, such as No. 0 to No. 5, are made in two to eight lengths.

Wood-Screw Holding Power.—One-half inch diameter wood-screws, driven 4 inches into wood, have a holding power of about 2500 pounds; 1/2-inch lag screws, driven 1½ inches into wood, have a holding power of about 1500 pounds, and, if driven 2½ inches into wood, of 2000 pounds. In all these tests the wood was Norway pine. Five-eighth-inch lag screws, driven 4½ inches into seasoned white oak, show a maximum holding power of 8000 pounds; the same screws driven into yellow pine, 4000 pounds.

www.EngineeringEBooksPdf.com

THREADS AND THREADING

Threads and Threading

History of Briggs Pipe Thread (NPT).—The USA (American) Standard for Pipe Threads, originally known as the Briggs Standard, was formulated by Mr. Robert Briggs. For several years around 1862 Mr. Briggs was superintendent of the Pascal Iron Works of Morris, Tasker & Company, Philadelphia, Pa., and later engineering editor of the "Journal" of the Franklin Institute. After his death on July 24, 1882, a paper by Mr. Briggs containing detailed information regarding American pipe and pipe thread practice, as developed by him when superintendent of the Pascal Iron Works, was read before the Institution of Civil Engineers of Great Britain. This is recorded in the Excerpt Minutes, Volume LXXI, Session 1882-1883, Part 1, of that Society.

It is of interest to note that the nominal sizes (diameters) of pipe ten (10) inches and under, and the pitches of the thread were for the most part established between 1820 and 1840.

By publishing his data, based on years of practice, Mr. Briggs was the means of establishing definite detail dimensions. The Briggs formula did not provide for the internal threads or gaging requirements for making taper threaded joints. It established only the external thread on pipe, with no tolerance.

In 1886 the large majority of American manufacturers threaded pipe to practically the Briggs Standard, and acting jointly with The American Society of Mechanical Engineers they adopted it as a standard practice that year, and master plug and ring gages were made.

Later at various conferences representatives of the manufacturers and the ASME established additional sizes, certain details of gaging, tolerances, special applications of the standard, and in addition tabulated the formulas and dimensions more completely than was done by Mr. Briggs.

Until the manufacturers adopted the Briggs thread in 1886, it seems that each manufacturer of necessity threaded his pipe and fittings according to his best judgment. After 1886 there was some attempt to work toward better interchangeability. However, the need for a better gaging practice resulted in the adoption of the thin ring gage and the truncation of the plug and ring gages to gage the flanks of the thread. This practice of threading fittings and couplings which provides threads to make up joints with a wrench was standardized about 1913.

In 1913 a Committee on the Standardization of Pipe Threads was organized for the purpose of re-editing and expanding the Briggs Standard. The American Gas Association and The American Society of Mechanical Engineers served as joint sponsors. After six years of work, this committee completed the revised standard for taper pipe thread which was published in the ASME "*Transactions*" of 1919, and was approved as an American Standard by the American Engineering Standards Committee, later named the American Standards Association in December 1919. It was the first standard to receive this designation under the ASA procedure, and was later published in pamphlet form.

In the years which followed, the need for a further revision of this American Standard became evident as well as the necessity of adding to it the recent developments in pipe threading practice. Accordingly, the Sectional Committee on the Standardization of Pipe Threads, B2, was organized in 1927 under the joint sponsorship of the A.G.A. and the ASME.

During the following 15 years, several meetings were held leading to approval by the members of the Sectional Committee, of the April 1941 draft. The revision was approved by the sponsors and ASA and published as an American Standard in October, 1942.

Shortly after publication of the 1942 standard, the Committee undertook preparation of a complete revision. The text and tables were rearranged and expanded to include Dryseal pipe threads, and an extensive appendix was added to provide additional data on the appli-

www.EngineeringEBooksPdf.com

cation of pipe threads and to record in abbreviated form the several special methods which were established for gaging some of the various applications of pipe threads.

The resulting proposal was approved by letter ballot of the Sectional Committee. Following its acceptance by the sponsor bodies, the draft was submitted to the American Standards Association and designated an American Standard on December 11, 1945.

At a subsequent meeting of the Sectional Committee it was agreed that for the convenience of users, the standards covering Dryseal pipe threads should be published under separate cover. Consequently, the section included in ASA B2.1-1945 on Dryseal pipe threads was deleted from the 1960 revision to that standard and used as a basis for the development of a separate proposal for Dryseal pipe threads. The text and tables were expanded to completely document the various series threads and gages, and appendices covering formulas, drilled hole sizes and special series threads were added. The E_1 internal diameter and the L_1 hand type engagements for the $\frac{1}{8}$ and $\frac{1}{4}$ inch sizes were revised to correct for a disproportionate number of threads for hand tight engagement. This proposal was approved by letter ballot vote of the Sectional Committee and submitted to the A.G.A. and the ASME. Following approval by the sponsor organizations, it was approved by the American Standards Association on April 29, 1960, and designated as ASA B2.1-1960, Pipe Threads (Except Dryseal).

The present revision of this standard constitutes a general updating. In line with their current policy, the A.G.A. has withdrawn sponsorship of this standard, while remaining active in the work of the standards committee. In compliance with the rules of the United States of America Standards Institute (formerly ASA) the previously designated Sectional Committees are now called Standards Committees.

Following approval by the Standards Committee B2 and the sponsor, ASME, the revision was approved by the United States of America Standards Institute on November 29, 1968.

Lock-Nut Pipe Thread.—The lock-nut pipe thread is a straight thread of the largest diameter which can be cut on a pipe. Its form is identical with that of the American or Briggs standard taper pipe thread. In general, "Go" gages only are required. These consist of a straight-threaded plug representing the minimum female lock-nut thread, and a straight-threaded ring representing the maximum male lock-nut thread. This thread is used only to hold parts together, or to retain a collar on the pipe. It is never used where a tight threaded joint is required.

Whitworth Thread Origin.—The work of the earlier generation of English tool builders culminated in that of Sir Joseph Whitworth. He, like most other English mechanics, was a North-country man, who had worked for both Maudslay and Clement. The succession of influence running through these men is singularly illustrated in the development of standard screw threads. Maudslay standardized the screw-thread practice of his own shop, settling upon and adhering to a definite number and size of threads for each size of screw then in use. Clement, who worked for Maudslay, adopted these standards, improved them, began the manufacture of taps and dies, and invented the tap having a small shank to enable it to fall through the tapped hole, thereby avoiding the necessity for backing out the tap. Whitworth took up the work of Clement and Maudslay, and, after making a careful study of all the threads in general use, proposed, in a paper before the Institute of Civil Engineers in 1841, the standard which became general throughout Great Britain and continues today as the Whitworth Standard thread. Most of the general tools had been invented by the time Whitworth began his independent work, but he so improved their design and workmanship that he influenced English tool practice for several generations. He introduced an accuracy in commercial work unknown until that time, which was made possible by his improvements in the methods of measurement.

Helix Angle.—If the base of a right-angle triangle equals the lead of a screw thread and if the altitude equals the pitch circumference of the screw, then the angle between the hypot-

www.EngineeringEBooksPdf.com

enuse and altitude of the triangle equals the helix angle of that screw thread at the pitch line; hence, the tangent of the helix angle equals the lead of the thread divided by the pitch circumference (circumference at one-half the thread depth). It is evident from the foregoing that the helix angle of a screw thread is measured from a plane perpendicular to the screw axis and it is usually known as the lead angle. This angle ordinarily is based upon the pitch diameter. If the helix angle at the top of a screw thread were required, the circumference at the outside diameter would be taken instead of the pitch circumference.The helix angle of a helical (spiral) gear is measured from the axis. Thus if the lead (axial distance that a tooth would advance if it made one complete turn) of a helical gear equals the base of a right-angle triangle and if the pitch circumference of the gear equals the altitude, then the angle between the hypotenuse and the base equals the helix angle; hence, the tangent of this helix angle equals the pitch circumference of the gear divided by the lead of the helix.

Thread Grinding.—Thread grinding is applied both in the manufacture of duplicate parts and also in connection with precision thread work in the tool-room.

Single-edged Grinding Wheel: In grinding a thread, the general practice in the United States is to use a large grinding wheel (for external threads) having a diameter of possibly 18 to 20 inches. The width may be 5/16 or $\frac{3}{8}$ inch. The face or edge of this comparatively narrow wheel is accurately formed to the cross-sectional shape of the thread to be ground. The thread is ground to the correct shape and lead by traversing it relative to the grinding wheel. This traversing movement, which is equivalent to the lead of the screw thread for each of its revolutions, is obtained from a lead-screw. On one type of thread grinder, this lead-screw is attached directly to the work-spindle and has the same lead as the screw thread to be ground; hence, there is a separate lead-screw for each different lead of thread to be ground. On another design of machine, the lead-screw arrangement is similar to that on a lathe in that the required lead on the ground thread is obtained by selection of the proper change gears. The grinding wheel may have a surface speed of 7000 feet a minute, whereas the work speed may range from 3 to 10 feet per minute. The grinding wheel is inclined to suit the helix angle of the thread and either right- or left-hand threads may be ground. Provision is also made for grinding multiple threads and for relieving taps and hobs. The wheel shape is accurately maintained by means of diamond truing tools. On one type of machine, this truing is done automatically and the grinding wheel is also adjusted automatically to compensate for whatever slight reduction in wheel size may result from the truing operation.

An internal thread may also be ground with a single-edged wheel. The operation is the same in principle as external thread grinding. The single-edged wheel is used whenever the highest precision is required, grinding the work either from the solid or as a finishing operation.

Grinding "from the Solid": On some classes of work, the entire thread is formed by grinding "from the solid," especially if the time required is less than would be needed for a rough thread-cutting operation followed by finish-grinding after hardening. Grinding threads from the solid is applied to the finer pitches. In some plants, threads with pitches up to about 1/16 inch are always ground by this method.

Multi-edged Grinding Wheel: An entire screw thread, if not too long, may be ground completely in one revolution by using a multi-edged type of grinding wheel. The face of this wheel is formed of a series of annular thread-shaped ridges so that it is practically a number of wheels combined in one. The principle is the same as that of milling screw threads by the multiple-cutter method. If the length of the thread to be ground is less than the width of the wheel, it is possible to complete the grinding in practically one work revolution as in thread milling. A grinding wheel having a width of, say, $2\frac{1}{2}$ inches, is provided with annual ridges or threads across its entire width. The wheel is fed in to the thread depth, and, while the work makes one single revolution, the wheel moves axially a distance equal

www.EngineeringEBooksPdf.com

to the thread lead along the face of the work. Most threads which require grinding are not longer than the width of the wheel; hence, the thread is completed by one turn of the work.

If the thread is longer than the wheel width, one method is to grind part of the thread and then shift the wheel axially one or more times for grinding the remaining part. For example, with a wheel 2½inches in width, a thread approximately 12 inches long might be ground in five successive steps. A second method is that of using a multi-edged tapering wheel which is fed axially along the work. The taper is to distribute the work of grinding over the different edges or ridges as the wheel feeds along.

Hand Chaser.—A hand chaser is a type of threading tool used either for cutting or chasing external or internal threads. The tool is supported upon a rest and is guided by the hand; it is used mainly on brass work, for slightly reducing the size of a thread that has been cut either by a die or threading tool. A hand chaser may also be used for truing up battered threads in repair work and for similar purposes.

Thread-Cutting Methods.—The two general methods of forming screw threads may be defined as the cutting method and the rolling or displacement method. The cutting methods as applied to external threads are briefly as follows:

1) By taking a number of successive cuts with a single-point tool that is traversed along the part to be threaded at a rate per revolution of the work depending upon the lead of the thread. (Common method of cutting screw threads in the engine lathe.)

2) By taking successive cuts with a multiple-point tool or chaser of the type used to some extent in conjunction with the engine lathe and on lathes of the Fox or monitor types.

3) By using a tool of the die class, which usually has four or more multiple-point cutting edges or chasers and generally finishes the thread in one cut or passage of the tool.

4) By a single rotating milling cutter, which forms the thread groove as either the cutter or the work is traversed axially at a rate depending upon the thread lead.

5) By a multiple rotating milling cutter which completes a thread in approximately one revolution of the work.

6) By a multiple rotating cutter which also has a planetary rotating movement about the work which is held stationary. See Planamilling and Planathreading.

7) By a grinding wheel having its edge shaped to conform to the groove of the screw thread.

8) By a multi-edged grinding wheel which, within certain limits as to thread length, will grind the complete thread in practically one revolution of the work.

Internal screw threads, or those in holes, may or may not be produced by the same general method that is applied to external work. There are three commercial methods of importance, namely:

1) By the use of a single-point traversing tool in the engine lathe or a multiple-point chaser in some cases.

2) By means of a tap which, in machine tapping, usually finishes the thread in one cut or passage of the tool.

3) By a rotating milling cutter of either the single or the multiple type.

Dies operated by hand are frequently used for small and medium-sized parts, especially when accuracy as to the lead of the thread and its relation to the screw axis is not essential and comparatively few parts need to be threaded at a time. When a large number of pieces must be threaded, power-driven machines equipped with dies are commonly employed. If the operation is simply that of threading the ends of bolts, studs, rods, etc., a “bolt cutter” would generally be used, but if cutting the thread were only one of several other operations necessary to complete the work, the thread would probably be cut in the same machine performing the additional operations. For instance, parts are threaded in turret lathes and automatic screw machines by means of dies and in conjunction with other operations. When screws are required which must be accurate as to the pitch or lead of the thread, and be true relative to the axis of the work, a lathe is generally used; lathes are also employed, ordi-

www.EngineeringEBooksPdf.com

narily, when the threaded part is comparatively long and large in diameter. Many threads which formerly were cut in the lathe are now produced by the milling process in special thread-milling machines. The method often depends upon the equipment at hand and the number of parts to be threaded. Very precise threads may be produced by grinding.

Taper Thread Cutting.—A tool for cutting tapered screw threads should be set as shown in Fig. 1a, or so that the sides of the thread incline equally with reference to a line perpendicular to the axis of the screw. The principal reason why taper threads should be cut with the tool in this position is that taper taps are made in this way or with the threads normal to the axis. If the tool were set in the position shown in Fig. 1b or Fig. 1c or so that the sides of the thread incline equally with reference to the tapering surface, obviously such a thread would be a poor fit in a hole tapped with an ordinary taper tap having threads normal to the axis as in Fig. 1a. If the hole and the tapering part which screws into it were both threaded normal to the surface as in Fig. 1b, the thread would be satisfactory unless there were an unusual amount of taper. In extreme cases, angle α (Fig. 1b) of one side of the thread might be so small that the radial or bursting pressure on the nut would be excessive owing to the wedging action.

Correct and Incorrect Positions of Tool for Taper Thread Cutting

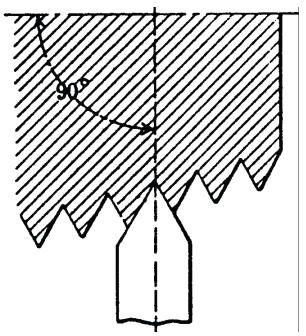

Fig. 1a.

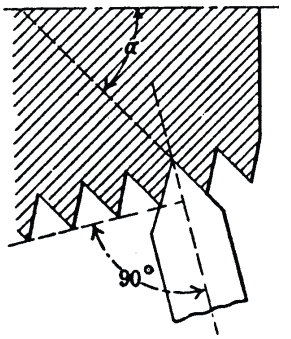

Fig. 1b.

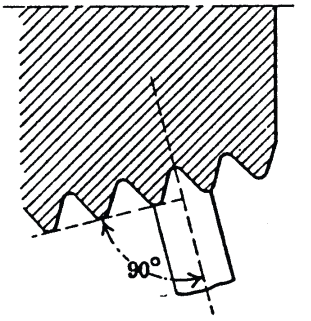

Fig. 1c.

Taps

A tap is an internal thread-cutting tool having teeth which conform to the shape of the thread. Taps may be classified according to the kind of thread with which they are provided, as U. S. Standard thread taps, square thread taps, and Acme thread taps, etc. The most important classification of taps, however, is according to their use.

Hand taps as the name implies, are intended primarily for tapping holes by hand but are often used in machines. All taps used by hand are not termed "hand" taps as there are many special taps used by hand which are known by specific names.

Tapper taps are used for tapping nuts in tapping machines. They are provided with a long chamfered part on the end of the threaded portion, and a long shank.

Machine nut taps are also used for tapping nuts in tapping machines. This type is designed for more severe duty than the tapper tap and is especially adapted for tapping holes in materials of tough structure. Machine nut taps are chamfered and relieved in a different, manner from tapper taps.

Machine screw taps may be either hand taps or machine nut taps, but are known by the name "machine screw tap," because they constitute a class of special taps used for tapping holes for standard machine screw sizes.

Screw machine taps for tapping in the screw machine are provided with shanks fitting either the turret holes of the machine or bushings inserted in these holes. As these taps ordinarily cut threads down to the bottom of the hole, they are provided with a very short chamfer.

www.EngineeringEBooksPdf.com

Pulley taps are simply a special type of taps used for tapping holes which cannot be reached by ordinary hand taps, as, for instance, the set-screw or oil-cup holes in the hubs of pulleys. They are simply hand taps with a very long shank.

Die taps also known as long taper die taps, are used for cutting the thread in a die in a single operation from the blank, and are intended to be followed by a sizing hob tap. Die taps are similar to machine nut taps.

Hob taps are used for sizing dies. They are intended only for the final finishing of the thread and can only take a slight chip. They are made to the same dimensions as regular hand taps, but fluted differently.

Pipe taps are used for tapping holes for standard pipe sizes. These tans are taper taps. There is also a special form of pipe tap termed *straight* pipe tap, which is simply a hand corresponding in diameter and number of threads per inch to standard pipe sizes.

Pipe hobs are similar to pipe taps, but are intended only for sizing pipe dies after the thread has been cut either by a pipe tap or in a lathe.

Boiler taps are used in steam boiler work where a steam-tight fit is required. They are made either straight or tapered. The straight boiler tap is practically only a hand tap.

Mud or washout taps are used in boiler or locomotive work. They are sometimes also called arch pipe taps. Patch bolt taps are used in boiler and locomotive work. These are taper taps similar to mud or washout taps.

Staybolt taps are used on locomotive boiler work. They are usually provided with a reamer portion preceding the threaded part, and have generally a long threaded portion and a long shank. A special form of staybolt tap is known as a spindle staybolt tap which revolves on a central spindle with a taper guide on the front end.

Stove-bolt taps and *carriage-bolt taps* are taps which have derived their names from the uses to which they were originally put. These taps have special forms of threads.

Bit-brace taps differ in no essential from the hand tap on the threaded portion, but are provided with a special shank for use in a bit brace.

Blacksmiths' taper taps are made for general rough threading and are used especially in repair work, where an accurately fitting thread is not required.

Inserted cutter taps may belong to any of the classes mentioned and constitute a separate type only because they are not solid, but have the cutting teeth on blades inserted and held rigidly in a tap body.

Tapping Lubricants.—Experiments have proved that the power required in tapping-that is, the resistance to the action of the tap when threading a nut-varies considerably with different lubricants. The following lubricants reduce the resistance to the cut when threading forged nuts, as well as those made from hexagon drawn material; the threads in the nut have a good finish and appearance: Stearine oil, lard oil, sperm oil, rape oil, and a mixture of 10 per cent graphite with 90 per cent tallow. A mixture of cutting emulsion with water also reduces the resistance to the threading action fairly well. In tests with emulsion, it was noted that it made very little difference how much water was mixed with the emulsion. A mixture of one part emulsion to 160 parts of water proved practically as good as a mixture of one part emulsion to ten parts of water.

Compound oils, that is, mineral oils mixed with animal or vegetable oils of the type usually employed for cooling lubricants for turning and milling, produce a considerably higher resistance than the animal or vegetable oils and cannot, therefore, be recommended for tapping. Mineral oils not mixed, and ordinary lubricating and machine oils, are wholly unsuitable. The resistance to cutting is very great, the taps break, and the threads in the nuts are badly torn; ordinary water reduces the cutting resistance better than some of the compound oils. Animal and vegetable oils, therefore, ought to be used exclusively for tapping.

Experiments on Lubricants for Tapping: Experiments conducted at Gothenburg, Sweden, on a large scale, indicate that the generalizations made from the earlier experiments, as recorded in the foregoing, are correct. Animal and vegetable oils are the best for tapping mild steel, and of these stearine oil and "Winter-strained" lard oil are preferable. Mineral

www.EngineeringEBooksPdf.com

oils machine oil were found to be wholly unsuitable. Compound oils containing less than 50 per cent of animal or vegetable oil acted much the same as the mineral oils and cannot be recommended for threading. When the compound oils contained over 50 per cent animal or vegetable oil, they could be used and were then found to be almost as good as the pure animal and vegetable oils.

A few emulsions have given almost as good results as animal and vegetable oils, but the kind of emulsion used plays an important part, and the majority of emulsions do not give good results. In almost all the tests made, a large volume of lubricant gave somewhat better results than a small quantity. This was particularly evident in the case of the thinner oils. Kerosene, turpentine, and graphite proved unsuitable for tapping steel.

With regard to the size of the hole tapped when different lubricants were used, it was found that the lubricant that produced the least resistance to tapping generally tended to produce the largest tapped hole. For example, when a hole was tapped dry, it would be a most accurate reproduction of the tap as far as size was concerned, but the threads were not clean and smooth, and, of course, the length of life of the tap was reduced. Water used as a lubricant produced good looking threads, but rather high resistance. Stearine oil, which reduced the resistance to tapping to the greatest extent, also produced the largest diameter in the hole.

For tapping aluminum, kerosene is recommended. For tapping cast iron use a strong solution of emulsion; oil has a tendency to make cast-iron chips clog in the flutes, thus preventing the lubricant from reaching the cutting teeth of the tap. For tapping copper, milk is a good lubricant.

Tap Drill Diameters.— Tapping troubles are often caused by using tap drills that are too small in diameter. For ordinary manufacturing, not more than 75 or 80 per cent of the standard thread depth is necessary, and for some classes of work not more than 50 per cent is required. Tap drill sizes, especially for machine screws, should be varied according to the material to be tapped and the depth of the tapped hole. The diameters of tap drills can be found by the formula $D = T - (0.75\ \ 2\ d)$, in which D drill diameter; T = diameter of tap or thread; d = depth of thread.

The diameters obtained by this formula allow for a thread having 75 per cent of the standard depth which is sufficient for general work. The full depth of an American Standard thread equals 0.6495 times the pitch of the thread, and the full depth of a British Standard Whitworth thread equals 0.6403 times the pitch.

GEARS, SPLINES, AND CAMS

Geometry Factors For Gear Teeth

Contact and Bending Stresses.—To calculate the contact and bending stresses acting between the teeth of a pair of gears meshing under load, it is necessary to include in the stress formulas a number of factors that account for the geometry of the teeth, the physical properties of the materials used, and the nature of the specific application.

AGMA 908-B89 Information Sheet* gives equations for calculating the pitting resistance geometry factor, *I*, for external and internal spur and helical gears; and the bending strength geometry factor, *J*, for external spur and helical gears that are generated by rack-type tools (hobs, rack cutters, or generating grinding wheels) or pinion-type tools (shaper cutters). The document includes 66 tables of geometry factors, *I* and *J*, for a range of typical gear sets and tooth forms of 14½-, 20-, and 25-deg pressure angles and 0-, 10-, 15-, 20-, 25-, and 30-deg helix angles.

The Information sheet was prepared to assist designers making preliminary design studies and to present data useful to those without access to computer programs. Not all tooth forms, pressure angles, and pinion and gear modifications are covered. Neither are these data applicable to all gear designs; however, the data should be helpful to the majority of gear designers. Data from this Information Sheet are used with the rating procedures described in AGMA 2001-B88, *Fundamental Rating Factors and Calculation Methods for Involute Spur and Helical Gear Teeth*, for evaluating various spur and helical gear designs produced by using a generating process (see page 3301).

Geometry Factors for Pitting Resistance and Bending Strength.—The AGMA Information Sheet includes a mathematical procedure to determine the pitting resistance geometry factor, *I*, for internal and external gear sets of spur, conventional helical, and low-axial-contact-ratio (LACR) helical design. A mathematical procedure is also included to determine the bending strength geometry factor, *J*, for external gear sets of spur, conventional helical, and low-axial-contact-ratio (LACR) helical designs. The calculation procedure is valid for generated root fillets produced by both rack- and pinion-type tools.

Exceptions to the Information Sheet Data and Procedures.—The formulas in the Information Sheet are not valid when any of the following conditions exist:

1) Spur gears with transverse contact ratio less than one, $m_p < 1.0$; 2) spur or helical gears with transverse contact ratio equal or greater than two, $m_p \geq 2.0$; 3) interference exists between the tips of teeth and root fillets; 4) the teeth are pointed; 5) backlash is zero; 6) undercut exists in an area above the theoretical start of the active profile (the effect of this undercut is to move the highest point of single tooth contact, negating the assumption of this calculation method; however, the reduction in tooth thickness due to protuberance below the active profile is handled correctly by this method); 7) the root profiles are stepped or irregular (the *J* factor calculation uses the stress correction factors developed by Dolan and Broghamer; the factors may not be valid for root forms that are not smooth curves; for root profiles that are stepped or irregular, other stress correction factors may be appropriate); 8) where root fillets of the gear teeth are produced by a process other than generating; and 9) the helix angle at the standard (reference) diameter is greater than 50 deg.

In addition to these exceptions, it is assumed that 1) the friction effect on the direction of force is neglected; and 2) the fillet radius is smooth (it is actually a series of scallops).

* Extracted from AGMA 908-B89, Information Sheet, *Geometry Factors for Determining the Pitting Resistance and Bending Strength of Spur, Helical, and Herringbone Gear Teeth*, with the permission of the publisher, American Gear Manufacturers Association, 1500 King Street, Suite 201, Alexandria, Virginia 22314.

www.EngineeringEBooksPdf.com

Basic Gear Geometry of Spur and Helical Gears.—The equations that follow apply to spur and helical gears. Where double signs are used (e.g.,±), the upper sign applies to external gears and the lower sign to internal gears. The equations given are based on unity normal module (m_n =1) or unity normal diametral pitch (P_{nd} = 1) and are valid for any consistent set of units. All angles are in radians unless otherwise specified. *In using the given equations, certain variables must be made dimensionless by dividing by the normal module m_n or multiplying by the normal diametral pitch P_{nd}.* For example, if a face width F 0.5 in. and the normal diametral pitch is 4, then the value of F to be used in the equations is $0.5 \times 4 = 2$. The variables to be so adjusted are F, R_{01}, R_{02}, R_{oc}, R_c, h_{ao}, δ_{ao}, ρ_{ao}, and Δ_{sn}.

$$\text{Gear ratio, } m_G = \frac{n_2}{n_1}, \text{ Where } n_1 \text{ and } n_2 \text{ are pinion and gear tooth numbers} \quad (1)$$

$$\text{Standard (reference) pinion pitch radius, } R_1 = \frac{n_1}{2\cos\psi} \quad (2)$$

Where ψ = standard helix angle.

$$\text{Standard (reference) gear pitch radius, } R_2 = R_1 m_G \quad (3)$$

$$\text{Standard transverse pressure angle, } \phi = \arctan\left(\frac{\tan\phi_n}{\cos\psi}\right) \quad (4)$$

Where ϕ_n = standard normal pressure angle.

$$\text{Pinion base radius, } R_{b1} = R_1\cos\phi \quad (5)$$

$$\text{Gear base radius, } R_{b2} = R_{b1} m_G \quad (6)$$

$$\text{Oparating transverse pressure angle, } \phi_r = \arccos\left(\frac{R_{b2} \pm R_{b1}}{C_r}\right) \quad (7)$$

Where C_r = Operating center distance.

$$\text{Transverse base pitch, } P_b = \frac{2\pi R_{b1}}{n_1} \quad (8)$$

$$\text{Normal base pitch, } P_N = \pi\cos\phi_n \quad (9)$$

$$\text{Base helix angle, } \psi_b = \arccos\left(\frac{P_N}{P_b}\right) \quad (10)$$

Fig. 1 shows a view of the line of action in the transverse plane of two meshing gears. The distances C_1, through C_6 are derived from this figure taking into account the exceptions noted previously with regard to undercut.

$$C_6 = C_r\sin\phi_r \quad (11)$$

$$C_1 = \pm[C_6 - (R_{02}^2 - R_{b2}^2)^{0.5}] \quad (12)$$

where R_{02} = addendum radius of gear, for internal or external gears.

$$C_3 = \frac{C_6}{(m_G \pm 1)} \quad (13)$$

$$C_4 = C_1 + P_b \quad (14)$$

www.EngineeringEBooksPdf.com

$$C_5 = (R_{01}^2 - R_{b1}^2)^{0.50} \tag{15}$$

Where R_{01} = addendum radius of pinion.

$$C_2 = C_5 - P_b \tag{16}$$

$$\text{Active length of line of contact, } Z = C_5 - C_1 \tag{17}$$

Distance C_2 locates the lowest point of single tooth contact (LPSTC); distance C_4 locates the highest point of single tooth contact (HPSTC), where C_r, R_{01}, and R_{02} are values for m_n =1 or P_{nd} =1.

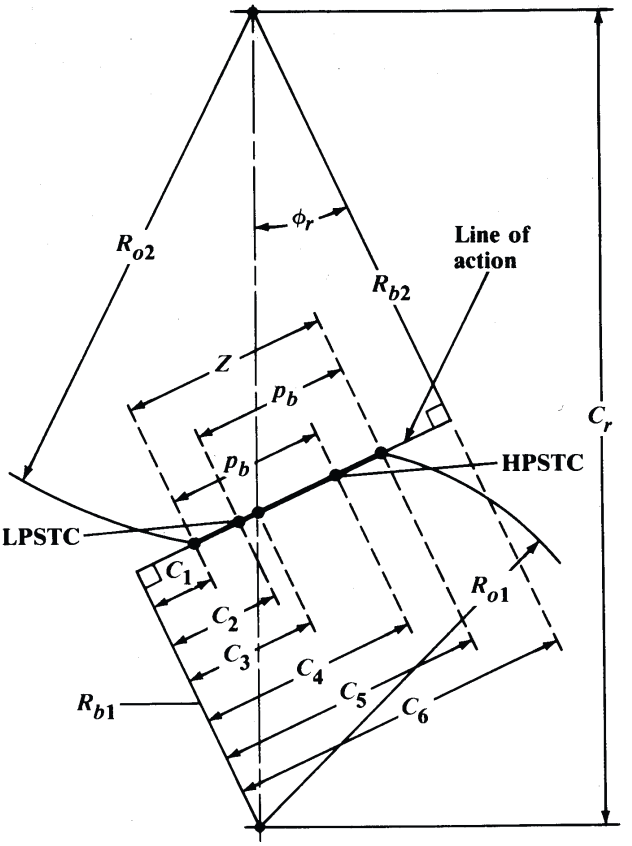

Fig. 1. Transverse Plane View of the Line of Action

Contact Ratios.—The contact ratios are as follows:

$$\text{Transverse Contact ratio, } m_p = \frac{Z}{P_b} \tag{18}$$

$$\text{Axial pitch, } P_x = \frac{\pi}{\sin\psi} \tag{19}$$

$$\text{Axial contact ratio, } m_F = \frac{F}{P_x} \tag{20}$$

where F = effective face width at m_n=1 or P_{nd} =1. For spur gears, m_F = 0.

www.EngineeringEBooksPdf.com

Minimum Lengths of Lines of Contact.—For spur gears with $m_p < 2.0$ the minimum length of contact lines, L_{min},

$$L_{min} = F \tag{21}$$

For helical gears, two cases must be considered:

$$\text{Case I: For } n_a \le 1 - n_r, L_{min} = \frac{(m_p F - n_a n_r p_x)}{\cos\psi_b} \tag{22}$$

$$\text{Case II: For } n_a > 1 - n_r, L_{min} = \frac{[m_p F - (1 - n_a)(1 - n_r)p_x]}{\cos\psi_b} \tag{23}$$

where n_r = fractional part of m_p, and n_a = fractional part of m_F. For example, if $m_p = 1.4$, then $n_r = 0.4$.

Load Sharing Ratio, m_N.—The load sharing ratio m_n, is calculated as follows:

$$\text{For helical gears, } m_N = \frac{F}{L_{min}} \tag{24}$$

$$\text{For spur gears with } m_p \le 2.0, \text{ Eq. (21) has } L_{min} = F \text{ so that } m_N = 1.0 \tag{25}$$

For low axial contact ratio (LACR) helicals, $m_F \le 1.0$. Load sharing is accommodated by the helical overlap factor C_ψ [Equation (36)]; therefore,

$$m_N = 1.0 \tag{26}$$

$$\text{Operating helix angle, } \psi_r = \arctan\left(\frac{\tan\psi_b}{\cos\phi_r}\right) \tag{27}$$

$$\text{Operating normal pressure angle, } \phi_{nr} = \arcsin(\cos\psi_b \sin\phi_r) \tag{28}$$

Calculating the Pitting Resistance Geometry Factor, *I*.— The pitting resistance geometry factor I is a dimensionless number that takes into account the effects of the radii of curvature of the gear tooth surfaces, load sharing, and the normal component of the transmitted load:

$$I = \frac{\cos\phi_r C_\psi^2}{[(1/\rho_1 + 1/\rho_2)(dm_N)]} \tag{29}$$

where

ϕ_r = operating transverse pressure angle [Equation (7)];
C_ψ = helical overlap factor [Equation (36)];
d = pinion operating pitch diameter [Equation (30)];
m_N = load sharing ratio [Equation (24), (25), or (26)]; and
$\rho_1 and \rho_2$ = radii of curvature of pinion and gear profiles, respectively, at point of stress calculation.

$$\text{Operating pitch diameter of pinion, } d = \frac{2c_r}{(m_G + 1)} \tag{30}$$

Radii of Curvature of Profiles at Contact Stress Calculation Point: For conventional helical gears ($m_F > 1$) the radii of curvature are calculated at the mean radius or middle of the working profile of the pinion where

www.EngineeringEBooksPdf.com

$$\text{Mean radius of pinion, } R_{m1} = \tfrac{1}{2}[R_{01} \pm (C_r - R_{02})] \tag{31}$$

where

R_{01} = addendum radius of pinion and;

R_{02} = addendum radius of gear, internal or external.

$$\text{radius of curvature of pinion profile, } \rho_1 = (R_{m1}^2 - R_{b1}^2)^{0.50} \tag{32}$$

Where R_{b1} = base radius of pinion.

$$\text{Radius of curvature of gear profile, } \rho_2 = C_6 \mp \rho_1 \tag{33}$$

For spurs and LACR helicals ($m_F \leq 1$), the radii of curvature are calculated at the LPSTC:

$$\rho_1 = C_2 \tag{34}$$

$$\rho_2 = C_6 \mp \rho_1 \tag{35}$$

Helical overlap factor for LACR ($m_F \leq 1$), helical gears,

$$C_\psi = \left[1 - m_F\left(1 - \frac{\rho_{m1}\rho_{m2}Z}{\rho_1\rho_2\rho_N}\right)\right]^{0.50} \tag{36}$$

where Z = Equation (17); p_N = Equation (9); ρ_{m1} = Equation (37) and, ρ_{m2} = Equation (38). radius of curvature of pinion profile at mean radius of profile,

$$\rho_{m1} = (R_{m1}^2 - R_{b1}^2)^{0.50} \tag{37}$$

Radius of curvature of gear profile at mean radius of gear,

$$\rho_{m2} = C_6 \mp \rho_{m1} \tag{38}$$

$$\text{For spur and conventional helicals, } C_\psi = 1 \tag{39}$$

Bending Strength Geometry Factor,* *J*.—The bending strength geometry factor is a dimensionless number that takes into account: 1) shape of the tooth; 2) worst load position; 3) stress concentration; and 4) load sharing between oblique lines of contact in helical gears .

Both tangential (bending) and radial (compressive) components of the tooth load are included. The equations and calculation procedures for the bending stress geometry factor are not given here, but may be found in AGMA 908-B89. The procedures apply only to external gears and must be repeated for both the pinion and the gear using the appropriate dimensions for each.

Generating Tool Geometry: Details of the methods for calculating the geometry of the tools used to generate tooth profiles are provided in the Information Sheet as part of the J-factor calculation procedure.

* Included in the AGMA Information Sheet are the equations needed to write a computer program to calculate values not given in the tables of *J* factors.

www.EngineeringEBooksPdf.com

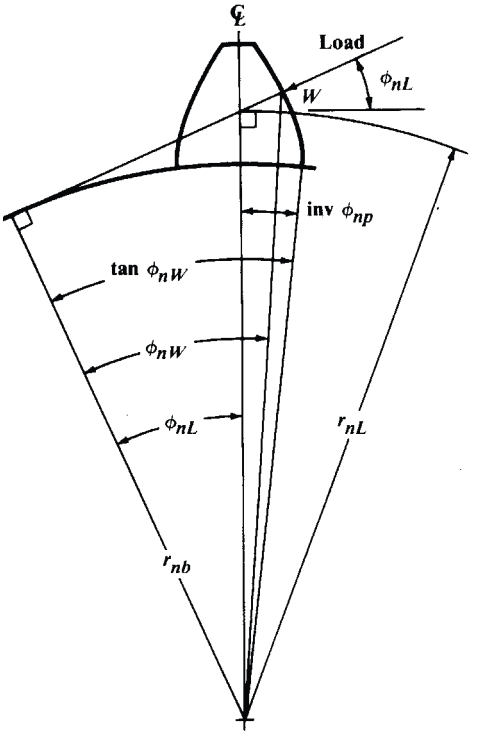

Fig. 2. Load Angle and Load Radius

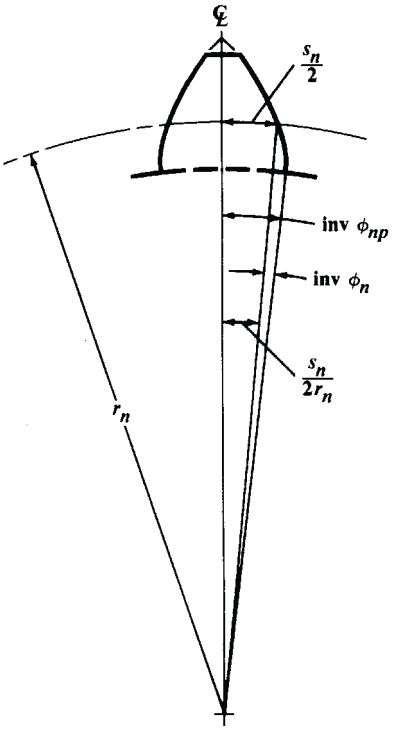

Fig. 3. Pressure Angle Where Tooth Comes to Point

Virtual Spur Gear: Helical gears are considered to be virtual spur gears with the following virtual geometry:

$$\text{Virtual tooth number, } n = \frac{n_1}{\cos\psi^3} \tag{40}$$

$$\text{Standard (ref) pitch radius of virtual spur gear, } r_n = \frac{n}{2} \tag{41}$$

$$\text{Virtual base radius, } r_{nb} = r_n \cos\phi_n \tag{42}$$

$$\text{Virtual outside radius, } r_{na} = r_n + R_{01} - R_1 \tag{43}$$

For spur gears, the virtual geometry is the same as the actual geometry:

$$n = n_1 \tag{44}$$

$$r_n = R_1 \tag{45}$$

$$r_{nb} = R_{b1} \tag{46}$$

$$r_{na} = R_{01} \tag{47}$$

Pressure Angle at Load Application Point.—The critical bending stress on a spur gear tooth develops when all the applied load is carried at the highest point of single tooth contact on the tooth. Spur gears having variations that prevent two pairs of teeth from sharing the load may be stressed most heavily when the load is applied at the tips of the teeth. Table 1 has been used in previous standards to establish the variation in base pitch between the

www.EngineeringEBooksPdf.com

gear and pinion, which determines whether load sharing exists in steel spur gears. Values greater than those in the table require the use of tip loading in determining bending stress geometry factors described in AGMA 908-B89.

Table 1. Maximum Allowable Variation in Action for Steel Spur Gears for Load Sharing (Variation in Base Pitch)

Number of Pinion Teeth	Load Pounds per Inch of Face (Newtons Per Millimeter of Face)				
	500 lb (90N)	1000 lb (175N)	2000 lb (350N)	4000 lb (700N)	8000 lb (1400N)
	Maximum Allowable Variation in Inches and Millimeters when Teeth Share Load				
15	0.0004 in. 0.01 mm	0.0007 in. 0.02 mm	0.0014 in. 0.04 mm	0.0024 in. 0.06 mm	0.0042 in. 0.11 mm
20	0.0003 in. 0.01 mm	0.0006 in. 0.02 mm	0.0011 in. 0.03 mm	0.0020 in. 0.05 mm	0.0036 in. 0.09 mm
25	0.0002 in. 0.01 mm	0.0005 in. 0.01 mm	0.0009 in. 0.02 mm	0.0017 in. 0.04 mm	0.0030 in. 0.08 mm

For helical gears and spur gears that are analyzed with the load applied at the tip of the tooth, the pressure angle at the load application point, ϕ_{nw}, is found from

$$\tan\phi_{nW} = \left[\left(\frac{r_{na}}{r_{nb}}\right)^2 - 1\right]^{0.50} \tag{48}$$

For spur gears, where the highest bending stress occurs when the load is at the highest point of single tooth contact (HPSTC), the pressure angle is found from

$$\tan\phi_{nW} = \frac{C_4}{r_{nb}} \tag{49}$$

Equation (49) may also be used for LACR helical gears, but distance C_4 must be based on the virtual spur gear. The following equations are from analogy with Equation (3), (6), (11), (12), (14), (44), and (49):

$$\text{Standard (ref) pitch radius of virtual spur gear, } r_{n2} = r_n m_G \tag{50}$$

$$\text{Virtual base radius, } r_{nb2} = r_{nb} m_G \tag{51}$$

$$\text{Virtual outside radius, } r_{na2} = r_{n2} + R_{02} - R_2 \tag{52}$$

$$\text{Sixth distance along line of action of virtual gear, } C_{n6} = (r_{nb2} + r_{nb})\tan\phi_{nr} \tag{53}$$

$$\text{First distance along line of action of virtual gear, } C_{n1} = [C_{n6} - (r_{na2}^2 - r_{nb2}^2)^{0.50}] \tag{54}$$

$$\text{Fourth distance along line of action of virtual gear, } C_{n4} = C_{n1} + \rho_N \tag{55}$$

The pressure angle at the load application point (tip), ϕ_{nW}

$$\tan\phi_{nW} = \frac{C_{n4}}{r_{nb}} \tag{56}$$

Generating-Rack Shift Coefficient.—The generating-rack shift coefficient, x_g, applies to the completely finished teeth. It includes the rack shift for addendum modification plus the rack shift for thinning the teeth to obtain backlash:

$$x_g = x - \frac{\Delta s_n}{2\tan\phi_n} \tag{57}$$

www.EngineeringEBooksPdf.com

where ΔS_n = amount gear tooth is thinned for backlash and x = addendum modification coefficient at zero backlash,

$$x = \frac{\left(S_n + \Delta S_n - \frac{\pi}{2}\right)}{(2\tan\phi_n)} \tag{58}$$

where S_n = normal circular tooth thickness measured on the standard (ret) pitch cylinder,

$$S_n = \frac{\pi}{2} + 2x_g \tan\phi_n \tag{59}$$

Load Angle and Load Radius: Fig. 2 defines the load angle ϕ_{nl} and the load radius r_{nl}. The applied load is shown at an arbitrary point W such that:

$$\phi_{nl} = \tan\phi_{nw} - \text{INV}\phi_{np} \tag{60}$$

where ϕ_{np} = pressure angle where gear tooth is pointed, Fig. 3.

$$\text{INV}\phi_{np} = \text{INV}\phi_n + \frac{s_n}{2r_n} \tag{61}$$

but,

$$\text{INV}\phi_n = \tan\phi_n - \phi \tag{62}$$

and

$$2r_n = n \tag{63}$$

so that

$$\text{INV}\phi_{np} = \tan\phi_n - \phi_n + \frac{s_n}{n} \tag{64}$$

Then Equation (60) can be expressed as

$$\phi_{nl} = \tan\phi_{nW} - \tan\phi_n + \phi_n - \frac{s_n}{n} \tag{65}$$

Equation (65) gives the load angle ϕ_{nL} for any load position specified by tan ϕ_{nW} found from Equation (48) and (49).

As may be seen from Fig. 3, the virtual radius is

$$r_{nl} = \frac{r_{nb}}{\cos\phi_{nL}} \tag{66}$$

Tables of Geometry Factors, *I* and *J*.—Included here are some of the tables of precalculated values of *I* and *J* extracted from the Information Sheet. For additional data, tables, and related information for other combinations of gear sets, tooth forms, pressure angles, helix angles, cutting tool dimensions, and addendum coefficients, refer to the Information Sheet. It should be noted that the formulas and data in the Information Sheet are not applicable to bending stresses in internal gears, since no simplified model for calculating bending stresses in internal gears is available.

Using the Tables.—Each of the tables in the Information Sheet and those presented here were generated for a specific tool form (basic rack) defined by whole depth factor, normal pressure (profile) angle, and tool tip radius. Only those tables applicable to spur gears are presented here; those for helical gear sets are available in the Information Sheet.

Whole Depth: Whole depth is expressed in the tables as a "whole depth factor" and is the whole depth of a basic rack for *I* normal module or *I* normal diametral pitch. The actual generated depths will be slightly greater due to tooth thinning for backlash

www.EngineeringEBooksPdf.com

Outside Diameter: The tabulated values are for gears having an outside diameter (for normal module or normal diametral pitch = 1), equal to

$$D_{a1} = \frac{n_1}{\cos\psi} + 2(1 + x_1) \tag{67}$$

$$D_{a2} = \frac{n_2}{\cos\psi} + 2(1 + x_2) \tag{68}$$

where n_1 and n_2 are the pinion and gear tooth numbers, respectively; ψ = standard helix angle, deg.; and D_{a1} and D_{a2} are the pinion and gear addendum, respectively.

Center Distance: The tables apply to gearsets that operate at standard center distance. This center distance is the tight-mesh center distance for gears not yet thinned for backlash:

$$C = \frac{(n_1 + n_2)}{2\cos\psi} \tag{69}$$

where C = standard center distance. For this center distance the sum of the addendum modification coefficients for pinion and gear is zero:

$$x_1 + x_2 = 0 \tag{70}$$

Tooth Thickness Backlash Allowance: Values in the tables were calculated based on a backlash allowance. The circular tooth thickness for the pinion and gear are each thinned by an amount Δsn:

$$\Delta s_n = \frac{0.024}{P_{nd}} = 0.024 \quad \text{for} \quad P_{nd} = 1 \tag{71}$$

If the gears being evaluated have different minimum tooth thicknesses than from Equation (71), the bending strength geometry factor, J, can be approximated by using Equation (72). The pitting resistance geometry factor, I, is unaffected by variations in tooth thickness:

$$J_1 = J_S\left(\frac{s_{n1}}{s_{ns}}\right)^2 \tag{72}$$

where J_1 = adjusted geometry factor; J_s = geometry factor from table; s_{n1} = adjusted circular tooth thickness; and s_{ns}= standard tooth thickness thinned per Equation (71).

As an example, from Table 4, for 20-deg pressure angle spur gears loaded at the highest point of single tooth contact, the J factor for a 21-tooth pinion operating with a 35-tooth gear is found to be 0.31. The table values are based on a circular tooth thickness of $\pi/2 - 0.024 = 3.1416/2 - 0.024 = 1.547$ for diametral pitch.

For a 10 normal diametral pitch pinion or gear, the equivalent circular tooth thickness would be 1.547/10 = 0.155.

If a J value for a 0.010 in. thinner pinion, having a circular thickness of 0.155 –0.010= 0.145 in. is required, the approximate value is $0.34(0.145/0.155)^2 = 0.30 = J_1$ so that a 6.5 per cent reduction in tooth thickness reduces the J factor by 12 percent.

Undercutting: The tables do not include geometry factors that may be needed if an undercutting condition exists in either of the two gears. Undercutting can be evaluated using Equation (73) and Fig. 4 where the generating-rack shift coefficient, x_g, must be equal to or greater than the expression in Equation (73):

$$x_{gmin} = h_{ao} - \rho_{ao}(1 - \sin\phi_n) - \left(\frac{n}{2}\right)\sin\phi_n{}^2 \tag{73}$$

www.EngineeringEBooksPdf.com

where h_{ao} = nominal tool addendum; ρ_{ao} = tool tip radius; and n = pinion or gear tooth number.

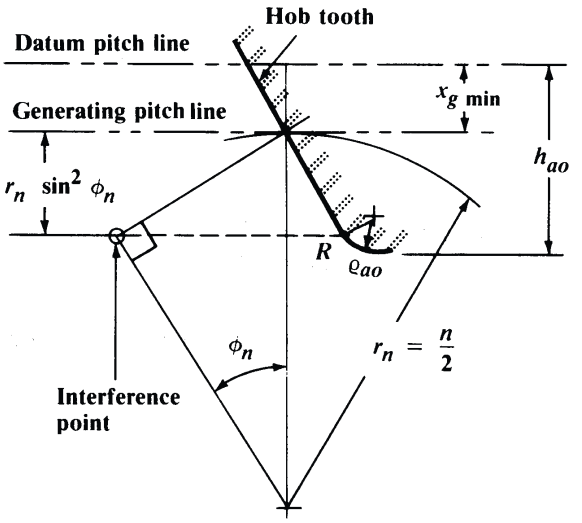

Fig. 4. Undercutting Criteria

Top Land: The tables do not include geometry factors when either the pinion or the gear tooth top land is less than the value expressed in Equation (74) or (74a):

$$s_{namin} \geq \frac{0.3}{P_{nd}} \quad \text{in.} \tag{74}$$

$$s_{namin} \geq 0.3 m_n \quad \text{mm} \tag{74a}$$

in which s_{na} = tooth thickness at outside diameter.

Cutter Geometry: The hob geometry used in the calculation of I and J is as follows: Tool tooth number, n_c = 10,000; reference normal circular tooth thickness of tool, s_{no} = 1.5708; addendum modification coefficient of tool, x_o = 0.0; amount of protuberance, δ_o = 0.0.

Power-Transmitting Capacity of Spur Gears

Modes of Failure.—When sets of spur gears are made, installed, and lubricated properly, they normally may be subject to three primary modes of failure, as discussed below.

Tooth Scoring: Tooth scoring is a scuffing or welding type of tooth failure, caused by high sliding speed combined with high contact stress. Scoring is not a fatigue failure but rather a failure of the lubricant caused by increases in lubricant viscosity with pressure. The lubricant must provide cooling to the gears as well as reducing friction. Well proportioned commercial gears with a pitchline velocity of less than 7000 ft/min will normally not score if they have a reasonably good surface finish and are properly lubricated. If scoring does occur or if it is suspected to be critical in a new high speed design, the scoring temperature index should be determined by the method shown in American Gear Manufacturers Standard AGMA 217.01 or by some similar method.

Pitting: In surface pitting, small cracks first develop on and under the surfaces of gear teeth as a result of metal fatigue. Pieces of the surface then break away, and those that do not fall clear cause further damage or broken teeth. Vacuum melted steels have gone far toward reducing pitting. Failure usually occurs at a point just below the pitch surface on the driving pinion and may be anticipated in the gear design by a determination of the gear set contact compressive stress.

Tooth Breakage: Tooth breakage is usually a tensile fatigue failure at the weakest section of the gear tooth when considered as a cantilever beam. The weakest point is normally the tensile side of the gear tooth fillet, and it may be anticipated in the gear design by determining the stress at this weakest section of the gear tooth.

Strength Calculations for Spur and Helical Gears.—Many standards and procedures for the design, manufacture, inspection, and application of gears have been published for the guidance of both the users and the manufacturers of gears and gear products. Among such publications, those of the American Gear Manufacturers Association (AGMA) represent an authoritative resource for information and standards on all phases of design, inspection, manufacture, application, and other aspects of gear technology.

American Gear Manufacturers Association Standard, AGMA 2001-B88, *Fundamental Rating Factors and Calculation Methods for Involute Spur and Helical Gear Teeth*, is a revision of, and supersedes, AGMA 218.01. The Standard presents general formulas for rating the pitting resistance and the bending strength of spur and helical involute gear teeth and is intended to establish a common base for rating various types of gears for differing applications and to encourage the maximum practical degree of uniformity and consistency between rating practices in the gear industry. Standard 2001-B88 provides the basis from which more detailed AGMA Application Standards are developed and is a means for calculation of approximate ratings in the absence of such standards. Where applicable AGMA standards exist, they should be used in preference to this Standard. Where no applicable standards exist, numerical values may be estimated for the factors used in the general equations presented in the standard. The values of these factors may vary significantly, depending on the application, system effects, gear accuracy, manufacturing practice, and definition of what constitutes gear failure. Proper evaluation of these factors is essential for realistic ratings.

Information on the geometry factors, I and J, used in pitting resistance and bending strength calculations has been amplified, and moved from the old AGMA 218.01 standard to AGMA 908-B89, *Geometry Factors for Determining the Pitting Resistance and Bending Strength of Spur, Helical, and Herringbone Gear Teeth*. AGMA Standard 908-B89 is covered starting on page 3285.

www.EngineeringEBooksPdf.com

Rating Formulas*.—AGMA 2001-B88 provides a method whereby different gear designs can be compared but it is not intended to ensure the performance of assembled gear drive systems. The formulas are applicable for rating the pitting resistance and bending strength of internal and external spur and helical involute gear teeth operating on parallel axes. Gear tooth capacity is influenced by the major factors that affect gear tooth pitting and gear tooth fracture at the fillet radius can be evaluated with these formulas.

Knowledge and judgment required to evaluate the various rating factors can be gained only from years of accumulated experience in designing, manufacturing, and operating gear units. Empirical factors given in the AGMA 2001-B88 standard are general in nature, and other AGMA application standards may use other empirical factors that are more closely suited to the particular field of application. AGMA 2001-B88 is intended for use by the experienced gear designer capable of selecting suitable values for the factors and not for use by engineers inexperienced in gear design and applications.

Exceptions.—The formulas in this Standard are not applicable to other types of gear tooth deterioration such as plastic yielding, wear, case crushing, and welding and are not applicable when vibratory conditions exceed the limits for the normal operation of the gears (see AGMA 6000-A88, *Specification for Measurement of Lateral Vibration on Gear Units*). The formulas are not applicable when any of the following conditions exist:

5) spur gears with transverse contact ratio less than 1.0; 6) spur or helical gears with transverse contact ratio equal to or greater than 2.0; 7) interference exists between the tips of the teeth and the root fillets; 8) the teeth are pointed; and 9) backlash is zero.

Additional Considerations.—When suitable test results or field data are not available, values for the rating factors should be chosen conservatively. Among other considerations, the following should be taken into account:

Manufacturing Tolerances: Rating factors should be evaluated on the basis of the expected variation of component parts in the production run.

Accuracy: Experimental data from actual gear unit measurements are seldom repeatable within a plus or minus 10 per cent band. Calculated gear ratings are intended to be conservative but the scatter in actual results may exceed 20 per cent.

Misalignment and Deflection of Foundations: Misalignment and deflection of foundations, on which many gear systems depend to maintain alignment of the gear mesh, will adversely affect overall performance.

Deflection due to External Loads: Deflection of supporting housings, shafts, and bearings, due to external overhang, transverse and thrust loads affects tooth contact across the mesh. Deflection varies with load, so it is difficult to obtain good tooth contact at different loads. Generally, deflection due to external loads reduces capacity.

Metallurgy: The allowable stress numbers included in the Standard are a function of melting, casting, forging, and heat treating practices. Hardness, tensile strength, and cleanliness are some of the criteria for determining allowable stress numbers; the allowable values in this Standard are based on 10,000,000 cycles of loading, 99 percent reliability, and unidirectional loading.

Variations in microstructure account for some variation in gear capacity. Higher levels of cleanliness and better metallurgical controls permit use of higher allowable stress values and, conversely, lower quality levels require the use of lower values.

Residual Stress: Any material having a case—core relationship is likely to have residual stresses. Properly managed, these stresses will be compressive at the surface and will enhance the bending strength performance of the gear teeth. Shot peening, case carburiz-

* Extracted from AGMA 2001-B88, Fundamental Rating Factors and Calculation Methods for Involute Spur and Helical Gear Teeth, with the permission of the publisher, American Gear Manufacturers Association, 1500 King Street, Suite 201, Alexandria, Virginia 22314.

www.EngineeringEBooksPdf.com

ing, nitriding, and induction hardening are common methods of inducing compressive prestress in the surfaces of gear teeth.

Grinding the tooth surfaces after heat treatment reduces residual compressive stresses; and grinding the tooth surfaces and the root fillet areas may introduce tensile stresses and possibly cracks in these areas if done incorrectly. Care is needed to avoid excessive reductions in hardness and changes in microstructure during the grinding process, and shot peening after grinding is often performed to ensure the presence of residual compressive stresses.

Lubrication: The ratings determined by the formulas in the Standard are only valid when a lubricant of proper viscosity for the load, gear-tooth surface finish, temperature, and pitchline velocity is used. Gears with pitchline velocities of less than 100 ft/min require special design considerations to avoid premature failure from inadequate lubrication.

Velocities greater than 100 ft/min but less than 1000 ft/min frequently require special design considerations even when the lubricants used conform to AGMA 250 recommendations.

With velocities in the range of 1000-10,000 ft/min, lubrication problems may be caused by high temperatures, unsuitable additives in the oil, size of the pinion, inadequate oil viscosity, or tooth finish characteristics. Problems in this speed range are not common in industrial gears but sometimes occur in aerospace and in marine gearing.

From a lubrication standpoint, the design of slower gears should be based on application criteria such as hours of life, degree of reliability needed, and acceptable increases in vibration and noise as the gear teeth wear or deform. At pitchline velocities below 100 ft/min, or 20 rpm input speed, the gear designer may allow for acceptable pitting and wear to occur during the gear life when using these rating practices for other than surface-hardened gearing. Rating of gear teeth due to wear is not covered by this Standard.

System Dynamics: The dynamic response of the system results in additional gear tooth loads due to the relative motions of the connected masses of the driver and the driven equipment. Application factors, C_a and K_a, are intended to account for the operating characteristics of the driving and driven equipment. However, if the operating roughness of the driver, gearbox, or driven equipment causes' an excitation with a frequency near to one of the system's major natural frequencies, resonant vibrations may cause severe overloads that may be several times higher than the nominal load. For more information, refer to AGMA 427.01, *Information Sheet-Systems Considerations for Critical Service Gear Drives*.

Corrosion: Corrosion of the gear tooth surface can have significant detrimental effects on the bending strength and pitting resistance of the teeth. The extent of these corrosion effects is not included in the Standard.

Cold Temperature Operation: For gears operated at temperatures below 320F, special care must be taken to select materials that will have adequate impact properties at the operating temperature. Consideration should be given to

1) low-temperature Charpy impact specification; 2) fracture appearance transition or nil ductility temperature specification; 3) reduction of carbon content to less than 0.4 per cent; and 4) use of higher nickel alloy steels.

Criteria for Gear Tooth Capacity

Relationship of Pitting Resistance and Bending Strength Ratings.—There are two major differences between the pitting resistance and the bending strength ratings. Pitting is a function of the Hertzian contact (compressive) stresses between two cylinders and is proportional to the square root of the applied load. Bending strength is measured in terms of the bending (tensile) stress in a cantilever plate and is directly proportional to this same load. The difference in the nature of the stresses induced in the tooth surface areas and at

www.EngineeringEBooksPdf.com

the tooth root is reflected in a corresponding difference in allowable limits of contact and bending stress numbers for identical materials and load intensities.

Analysis of the load and stress modifying factors is similar in each instance, so many of these factors have identical numerical values. The term “gear failure” is itself subjective and a source of considerable disagreement. One observer’s “failure” may be another observer’s “wearing in.” A more complete discussion of “failure” is given in AGMA 110.04, Nomenclature of Gear Tooth Failure Modes.

Pitting Resistance: In most industrial practice, corrective and nonprogresssive initial pitting is not deemed serious. Initial pitting is characterized by small pits that do not extend over the entire face width or profile height of the affected teeth. The definition of acceptable pitting varies widely with gear application. Initial pitting occurs in localized, overstressed areas and tends to redistribute the load by progressively removing high contact spots. Generally, when the load has been reduced or redistributed, the pitting stops.

The pitting resistance formula aims to determine a load rating at which destructive pitting of the teeth does not occur during their design life. The ratings for pitting resistance are based on the formulas developed by Hertz for contact pressure between two curved surfaces, modified for the effect of load sharing between adjacent teeth.

Bending Strength: The bending strength of gear teeth is a fatigue phenomenon related to the resistance to cracking at the tooth root fillet in external gears and at the critical section in internal gears. The basic theory employed in this analysis assumes the gear tooth to be rigidly fixed at its base, thus, the critical stress occurs in the fillet. If the rim supporting the gear tooth is thin relative to the size of the tooth and the gear pitch diameter, another critical stress may occur not at the fillet but in the root area. The rim thickness factor, KB, adjusts the calculated bending stress number for thin rimmed gears.

The strength ratings determined by this Standard are based on plate theory that is modified to consider:

1) the compressive stress at tooth roots caused by the radial component of tooth loading; 2) nonuniform moment distribution resulting from the inclined angle of the load lines on the teeth; 3) stress concentrations at the tooth root fillets; and 4) the load sharing between adjacent teeth in contact.

The intent of the AGMA strength rating formula is to determine the load that can be transmitted for the design life of the gear drive without causing cracking or failure. Occasionally, wear, surface fatigue, or plastic flow may limit bending strength due to stress concentrations around large, sharp cornered pits or wear steps on the tooth surface.

Fundamental Rating Formulas.—The symbols and definitions used in the pitting resistance and bending strength formulas are shown in Table 1. SI units are shown in parentheses in Table 1 and in the text. Where equations require a different format or constant for use with SI units, a second expression is shown after the first and with M included in the equation number at the right.

Pitting Resistance.—The fundamental formula for pitting resistance of gear teeth is

$$S_c = C_p \sqrt{\frac{W_t \times C_a}{C_v} \frac{C_s}{dF} \frac{C_m \times C_f}{I}} \tag{1}$$

where the meaning of the symbols is as shown in Table 1 and,

$$d = \frac{2C}{m_G + 1.0} \quad \text{for external gears} \tag{2}$$

$$d = \frac{2C}{m_G - 1.0} \quad \text{for internal gears} \tag{3}$$

Table 1. *(Continued)* **Symbols Used in Gear Rating Equations**

Symbol	Description of Symbols and Units	Symbol	Description of Symbols and Units
E_p	Modulus of elasticity for pinion, lb/in.^{2} (MPa)	S_{ac}	Allowable contact stress number,lb/in.^{2} (MPa)
e_t	Total lead mismatch, in. (mm)	S_{at}	Allowable bending stress number,lb/in.^{2} (MPa)
f_p	Pinion surface finish, microinches rms	S_{ay}	Allowable yield stress number, lb/in.^{2} (MPa)
F	Net face width of narrowest member, in. (mm)	S_c	Contact stress number, lb/in.^{2} (MPa)
G	Tooth stiffness constant, lb/in.^{2} (MPa)	S_t	Bending stress number, lb/in.^{2} (MPa)
H_{BG}	Brinell hardness of gear	T	Transmitted pinion torque, lb-in.(N-m)
H_{Bp}	Brinell hardness of pinion	t_R	Gear rim thickness, in. (mm)
h_c	Minimum total case depth for nitrided gears, in. (mm)	t_o	Normal tooth thickness at top land ofgear, in. (mm)
h_e	Minimum effective case depth for carburized gears, in. (mm)	U_{at}	Allowable unit load for bending-strength, lb/in.^{2} (MPa)
$h_{e\,max}$	Maximum effective case depth, in. (mm)	U_c	Core hardness coefficient
h_t	Gear tooth whole depth, in. (mm)	U_H	Hardening process factor
I	Geometry factor for pitting resistance	U_L	Unit load for bending strength, lb/in.^{2} (MPa)
J	Geometry factor for bending strength	v_t	Pitch line velocity at operating pitchdiameter, ft/min (m/s)
K	Contact load factor for pitting resistance, lb/in.^{2} (MPa)	$v_{t\,max}$	Pitch line velocity maximum atoperating pitch diameter, ft/min (m/s)
K_a	Application factor for bending strength	W_d	Incremental dynamic tooth load,lb (N)
K_{ac}	Allowable contact load factor, lb/in.^{2} (MPa)	W_{max}	Maximum peak tangential load, lb (N)
K_B	Rim thickness factor	W_t	Transmitted tangential load, lb (N)
K_f	Stress correction factor	Y	Tooth form factor
K_L	Life factor for bending strength	Z	Length of action in transverse plane, in. (mm)
K_m	Load distribution factor for bending strength	μ_G	Poisson's ratio for gear
		μ_P	Poisson's ratio for pinion
		ϕ_t	Operating transverse pressure angle
		ψ_s	Helix angle at standard pitch diameter
		ψ_b	Base helix angle

Allowable Contact Stress Number: The relation of calculated contact stress number (graphed in Fig. 1) to the allowable contact stress number is

$$S_c \le S_{ac} \frac{C_L C_H}{C_T C_R} \tag{4}$$

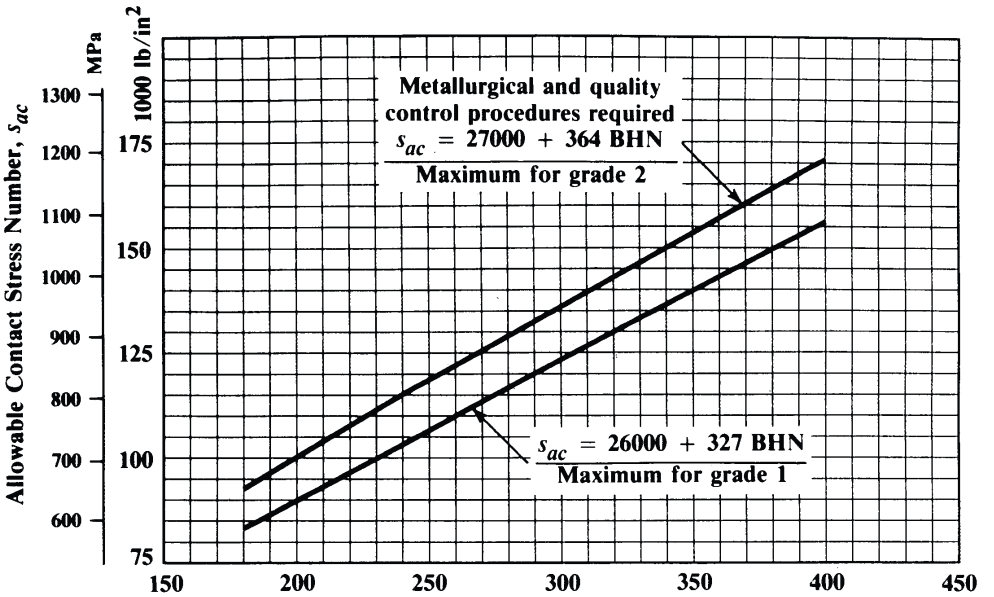

Fig. 1. Allowable Contact Stress Number for Steel Gears, S_{ac}

Pitting Resistance Power Rating.—The pitting resistance power rating is given by

$$P_{ac} = \frac{n_p \times F}{12600} \frac{I \times C_v}{C_s \times C_m \times C_f \times C_a} \left(\frac{d \times S_{ac}}{C_p} \frac{C_L \times C_H}{C_T \times C_R} \right)^2 \tag{5}$$

$$P_{ac} = \frac{n_p \times F}{1.91 \times 10^7} \frac{I \times C_v}{C_s \times C_m \times C_f \times C_a} \left(\frac{d \times S_{ac}}{C_p} \frac{C_L \times C_H}{C_T \times C_R} \right)^2 \tag{5a}$$

In using Formula (5) and (5a), the ratings of both pinion and gear must be calculated to evaluate differences in material properties and the number of cycles under load. The pitting resistance power rating is based on the lowest value of the product $S_{ac}\, C_L C_H$ for each of the mating gears.

Contact Load Factor, *K*.—In some industries, pitting resistance is rated in terms of a *K* factor:

$$K = \frac{W_t}{dF} \times \frac{1}{C_G} \tag{6}$$

$$\text{for external geras,} \quad C_G = \frac{N_G}{N_G + N_P} \tag{7}$$

$$\text{for internal geras,} \quad C_G = \frac{N_G}{N_G - N_P} \tag{8}$$

In terms of this Standard, the allowable *K* factor is defined as

www.EngineeringEBooksPdf.com

$$K_{ac} = \frac{I}{C_G}\frac{C_v}{C_a \times C_s \times C_m \times C_f}\left(\frac{S_{ac} \times C_L \times C_H}{C_p \times C_T \times C_R}\right)^2 \tag{9}$$

The allowable contact load factor, K_{ac}, is the lowest of the ratings calculated using the different values of s_{ac}, C_L, and C_H for pinion and gear.

Bending Strength.—The fundamental formula for bending stress number in a gear tooth is

$$s_t = \frac{W_t \times K_a}{K_v}\frac{P_d}{F}\frac{K_s \times K_m \times K_B}{J} \tag{10}$$

where $P_d = P_{nd}$ for spur gears. For helical gears, P_d is given by Equation (11),

$$s_t = \frac{W_t \times K_a}{K_v}\frac{I}{F \times m}\frac{K_s \times K_m \times K_B}{J} \tag{10a}$$

where $m = m_n$ for spur gears. For helical gears m is given by Equation (11a):

$$P_d = \frac{\pi}{p_x \tan\psi_s} = P_{nd}\cos\psi_s \tag{11}$$

$$m = \frac{P_x \times \tan\psi_s}{\pi} = \frac{m_n}{\cos\psi_s} \tag{11a}$$

where ψ_s is given by Equation (12) or (12a)

$$\psi_s = \operatorname{asin}\left(\frac{\pi}{p_x \times P_{nd}}\right) \tag{12}$$

$$\psi_s = \operatorname{asin}\left(\frac{\pi \times m_n}{p_x}\right) \tag{12a}$$

Allowable Bending Stress Number.—The relation of calculated bending stress number to allowable bending stress number is

$$S_t \le \frac{S_{at} \times K_L}{K_T \times K_R} \tag{13}$$

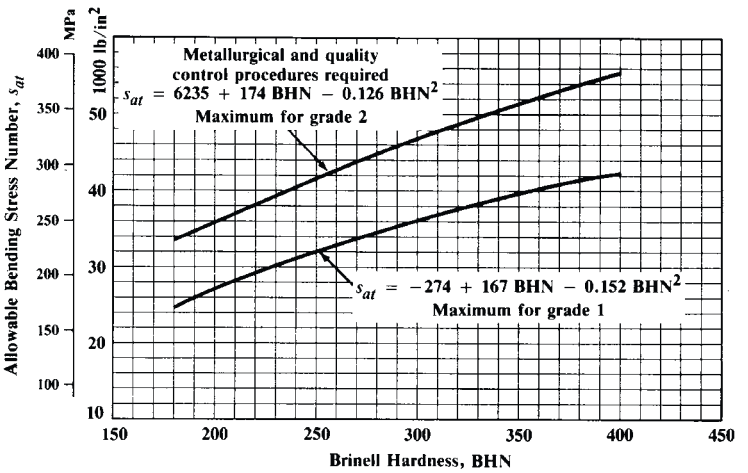

Fig. 2. *Allowable Bending Stress Number for Steel Gears* s_{at}

www.EngineeringEBooksPdf.com

Bending Strength Power Rating.—The bending strength power rating is

$$P_{at} = \frac{n_p \times d \times K_v}{126000 \times K_a} \frac{F}{P_d} \frac{J}{K_s \times K_m \times K_B} \frac{s_{at} \times K_L}{K_R \times K_T} \tag{14}$$

$$P_{at} = \frac{n_p \times d \times K_v}{1.91 \times 10^7 \times K_a} \frac{F \times m \times J}{K_s \times K_m \times K_B} \frac{s_{at} \times K_L}{K_R \times K_T} \tag{14a}$$

The ratings of both pinion and gear must be calculated to evaluate differences in geometry factors, number of load cycles, and material properties. The bending strength power rating is based on the lowest value of the term $S_{at}K_LJ/K_B$ for each of the mating gears.In some industries, the bending strength is rated in terms of unit load:

$$U_L = \frac{(W_t \times P_{nd})}{F} \tag{15}$$

$$U_L = \frac{W_t}{(F \times m)} \tag{15a}$$

The allowable unit load, U_{at}, is the lowest of the ratings calculated using the different values of S_{at}, K_B, K_L, and J for pinion and gear in Equation (16):

$$U_{at} = \frac{J}{\cos\psi} \frac{K_v}{K_a \times K_m \times K_s \times K_B} \frac{s_{at} \times K_L}{K_R \times K_T} \tag{16}$$

Values for Factors Applied in Fundamental Equations.—Values for the various factors used in the pitting resistance and bending strength rating equations are discussed and explained in greater detail in the Standard and its appendices than can be provided here. The following paragraphs are intended by the Editors to provide values for some of these factors suitable for making approximations to the ratings of pairs of mating gears without the refinements used by experienced gear designers.

Rim Thickness Factor K_B.—The rim thickness factor, K_B, is used to adjust the calculated bending stress number for thin rimmed gears, the value of the factor depending upon the backup ratio,

$$m_B = \frac{t_R}{h_t} \tag{17}$$

If m_B is equal to or greater than 1.2, then K_B may be taken as 1.0. For values of m_B less than 1.2, see the information in Appendix C following the Standard.

Geometry Factors *I* and *J*.—The geometry factors I and J for pitting resistance and bending strength, respectively, are described, along with selected typical values, beginning on page 3285.

Transmitted Tangential Load, W_t.—In most gear applications the torque is not constant, so the transmitted tangential load will vary. To obtain values of the operating transmitted tangential load, W_t, the values of power and speed at which the driven device will operate should be used. If the rating is calculated on the basis of uniform load, then the transmitted tangential load is

$$W_t = \frac{33000 \times P}{v_t} = \frac{2 \times T}{d} = \frac{126000 \times P}{n_p \times d} \tag{18}$$

$$W_t = \frac{1000 \times P}{v_t} = \frac{2000 \times T}{d} = \frac{1.91 \times 10^7 \times P}{n_p \times d} \tag{18a}$$

www.EngineeringEBooksPdf.com

where,

$$v_t = \frac{(\pi \times n_p \times d)}{12} \tag{19}$$

$$v_t = \frac{(\pi \times n_p \times d)}{60000} \tag{19a}$$

Nonuniform Load: When the transmitted load is not uniform, consideration should be given not only to the peak load and its anticipated number of cycles, but also to intermediate loads and their duration. This type of load is often considered a duty cycle and may be represented by a load spectrum. The cumulative fatigue effect of the duty cycle is then considered in rating the gearset, A method of calculating the effects of the loads under such conditions is given in Appendix B of the Standard.

Dynamic Factors, C_v and K_d.—Dynamic factors account for internally generated gear tooth loads, which are induced by nonconjugate meshing action of the gear teeth. Even if the input torque and speed are constant, significant vibration of the gear masses, and therefore dynamic tooth forces, can exist. These forces result from the relative displacements between the gears as they vibrate in response to an excitation known as "transmission error." Ideally, a gearset would have a uniform velocity ratio between the input and output rotation. Transmission error is defined as the departure from uniform relative angular motion of the pair of meshing gears. It is influenced by all the deviations from the ideal gear tooth form.

The dynamic factor relates the total tooth load, including internal dynamic effects, to the transmitted tangential tooth load:

$$C_v = K_v = \frac{W_t}{W_d \times W_t} \tag{20}$$

where W_d = incremental dynamic tooth load due to the dynamic response of the gear pair to the transmission error excitation, excluding the transmitted tangential load W_t.

Excitation: The transmission error contributing to the dynamic factors is influenced by:

1) Manufacturing variations such as spacing, profile, lead, and runout.

2) Gear mesh stiffness variation as the gear teeth pass through the meshing cycle. This source of excitation is especially pronounced in spur gears without profile modification. Spur gears with properly designed profile modification, and helical gears with axial contact ratios greater than 1.0, have a smaller stiffness variation.

3) Transmitted load. Since elastic deflections are load dependent, gear tooth profile modifications can be designed to give a uniform velocity ratio at only one load magnitude.

4) Pitchline velocity. The frequencies of the excitation depend on the pitchline velocity.

5) Dynamic imbalance of the gears and shafts.

6) Excessive wear and plastic deformation of the gear tooth profiles increase the amount of transmission error.

7) Shaft alignment. Gear tooth alignment is influenced by load and thermal distortions of the gears, shafts, bearings, and housings, and by manufacturing variations.

8) Tooth friction induced excitation.

Dynamic Response: The dynamic tooth forces are influenced by:

1) Mass of the gears, shafts, and other major internal components.

2) Stiffness of the gear teeth, gear blanks, shafts, bearings, and gear housings.

3) Damping. The principal source of coulomb or viscous damping is the shaft bearings. Generally, oil film bearings provide greater damping than rolling element bearings. Other sources of damping include the hysteresis of the gear shafts, and viscous damping at sliding interfaces and shaft couplings.

www.EngineeringEBooksPdf.com

Resonance: When an excitation frequency coincides with a natural frequency, the resonant response is limited only by the damping, and high dynamic loads may result. The dynamic factors C_v and K_d do not apply to resonance.

Gear Pair Resonance: If a particular frequency of the transmission error excitation is close to the natural frequency of the gear masses, or some multiple of the natural frequency such as ½ or 2, a resonant vibration may cause high dynamic tooth forces due to large relative displacements of the gear masses. The dynamic factors C_v and K_d do not account for gear pair resonance and operation in this regime is to be avoided.

Gear Blank Resonance: Gear blanks may have natural frequencies within the operating speed range. If the gear blank is excited by a frequency that is close to one of its natural frequencies, the resonant deflections may cause high dynamic tooth loads. This phenomenon occurs more frequently in high speed, light weight gear blanks, but can also occur in other thin rimmed or thinwebbed blanks. The dynamic factors C_v and K_d do not account for gear blank resonance. A separate investigation is recommended when these conditions arise.

System Resonance: The gearbox is one component of a system comprised of a power source, gearbox, driven equipment, and interconnecting shafts and couplings. The dynamic response of this system depends on the distribution of the masses, stiffness, and damping. In certain designs, a system may possess a torsional natural frequency close to an excitation frequency associated with an operating speed. Under these resonant conditions the dynamic tooth loads may be high, and operation near such a system resonance is to be avoided. The dynamic factors C_v and K_d do not include considerations of the dynamic loads due to torsional vibration of the gear system. These loads must be included with other externally applied forces in the application factors C_a and K_a. For critical drives, a separate dynamic analysis of the entire system is recommended.

Shaft Critical Speeds: Owing to their high bending stiffness, the natural frequency of lateral vibrations of the gear shafts are usually much higher than the operating speeds. However, for high speed gears it is recommended that the critical speeds be analyzed to ensure that they are well removed from the operating speed range. The dynamic factors C_v and K_d do not account for the dynamic tooth loads due to this mode of vibration.

Nonlinear Resonance: Large cyclical variation in gear mesh stiffness and impact loads may lead to additional regions of resonance and instability. This problem appears primarily with lightly loaded, lightly damped spur gears that do not have profile modifications.

Approximate Dynamic Factors: Fig. 3 shows dynamic factors that can be used in the absence of specific knowledge of the dynamic loads. The curves of Fig. 3 are based on equations in the Standard derived from empirical data and do not account for resonance.

Choice of which of curves 5 through 11 of Fig. 3 to use should be based on transmission error. When transmission error data are unavailable, it is reasonable to use pitch (spacing) and profile accuracy. Q_v is the transmission accuracy level number. It can be the same as the quality number for the lowest quality member in the mesh from AGMA 2000-A88 when manufacturing techniques ensure equivalent transmission accuracy, or when the pitch (spacing) and profile accuracy are the same as AGMA 2000-A88 tolerances.

Owing to the approximate nature of the empirical curves and the lack of measured tolerance values at the design stage, the dynamic factor curve should be selected based on experience with the manufacturing methods and operating considerations of the design.

The curves in Fig. 3 are referenced only by spacing and profile, and actual dynamic load is influenced by many other factors, so slight variations from the selected tolerances are not considered significant to the gearset rating.

www.EngineeringEBooksPdf.com

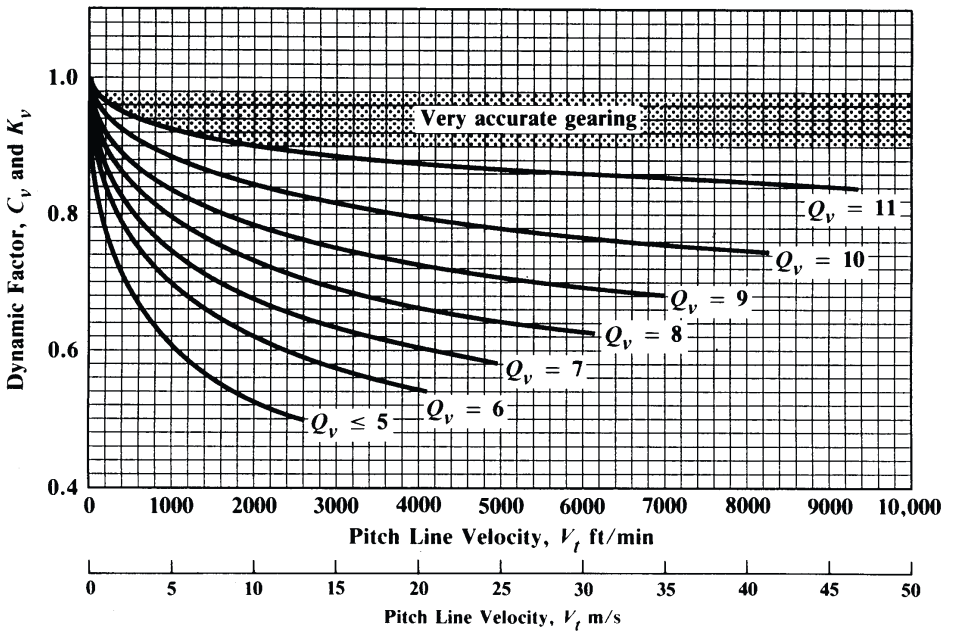

Fig. 3. Dynamic Factors, C_v and K_d

Very Accurate Gearing: Where gearing is manufactured using process controls that correspond to $Q_v \geq 12$ limits, or where the design and manufacturing techniques ensure a low transmission error equivalent to this accuracy, values of C_v and K_d between 0.90 and 0.98 may be used, depending on the specifier's experience with similar applications and the degree of accuracy actually achieved. To use these values, the gearing must be maintained in accurate alignment and adequately lubricated so that its accuracy is maintained under the operating conditions. Spur gears should have properly designed profile modification and helical gears should have an axial contact ratio greater than 1.0.

Curves Numbered 6 through 11 on Fig. 3: These curves are generated by equations in the Standard for values of Q_v such that $6 \leq Q_v \geq 11$.

Unity Dynamic Factor: When the known dynamic loads (from analysis or experience) are added to the nominal transmitted load, then the dynamic factor can be taken to be 1.0.

Application Factors, C_a and K_a.—These application factors make allowance for any externally applied loads in excess of the nominal tangential load W_t. Application factors can only be established after considerable field experience is gained in a particular application.

In determining the application factor, consideration should be given to the fact that many prime movers develop momentary peak torques appreciably greater than those determined by the nominal ratings of either the prime mover or the driven equipment. Many possible sources of overload should be considered. Some of these are system vibrations, acceleration torques, overspeeds, variations in system operation, split path load sharing among multiple prime movers, and changes in process load conditions. When operating near a critical speed of the drive system, a careful analysis of conditions must be made.

Service Factors, C_{SF} and K_{SF}.—These service factors have been used to include the combined effects of C_L, C_R, C_a and K_L, K_R, K_a, respectively, in an empirically determined single factor. The mathematical contribution of each of these factors has not been established, so that, in the absence of more specific load data, a service factor may be used. When a ser-

www.EngineeringEBooksPdf.com

vice factor is used, the power rating formulas [Equation (5) and (5a)] would be modified as follows:

$$P_{ac} = \frac{n_p \times F}{126000} \frac{I \times C_v}{C_{sf} \times C_s \times C_m \times C_f} \left(\frac{d \times s_{ac}}{C_p} \frac{C_H}{C_T} \right) \tag{21}$$

$$P_{ac} = \frac{n_p \times F}{1.91 \times 10^7} \frac{I \times C_v}{C_{sf} \times C_s \times C_m \times C_f} \left(\frac{d \times s_{ac}}{C_p} \frac{C_H}{C_T} \right) \tag{21a}$$

$$P_{at} = \frac{n_p \times d \times K_v}{126000 \times K_{SF}} \frac{F}{P_d} \frac{J}{K_s \times K_m \times K_B} \frac{s_{at}}{K_T} \tag{22}$$

$$P_{at} = \frac{n_p \times d \times K_v}{1.91 \times 10^7 \times K_{SF}} \frac{F \times m \times J}{K_s \times K_m \times K_B} \frac{s_{at}}{K_T} \tag{22a}$$

where C_{SF} and K_{SF} are service factors for pitting resistance and bending strength, respectively.

Teeth of both the pinion and the gear must be checked to account for differences in material properties, geometry factors, and the number of cycles under load. The power rating is then based on the lowest values of the following expressions for each of the mating gears:

for pitting resistance $\frac{(s_{ac} \times C_H)^2}{C_{SF}}$, and for bending strength $\frac{s_{at} \times J}{K_{SF}}$.

Elastic Coefficient, C_p.—The elastic coefficient, C_p, is defined by the equation

$$C_p = \sqrt{\frac{1.0}{\pi \left[\left(\frac{1.0 - \mu_P^2}{E_p} \right) \div \left(\frac{1.0 - \mu_G^2}{E_G} \right) \right]}} \tag{23}$$

The value of C_p for a steel gear meshing with a steel pinion is 2300 $[\text{lb/in.}^2]^{0.5}$, or 191 $(\text{MPa})^{0.5}$, approximately. Approximate values for other combinations of materials are given in the Standard.

Surface Condition Factor, C_f.—The surface finish factor used only in the pitting resistance formulas has not yet been established for conditions where there is a detrimental surface finish effect. Where such effects are encountered, a surface condition factor greater than unity should be used.

Size Factors, C_s and K_s.—The size factor reflects nonuniformity of material properties and depends primarily on tooth size, diameter of parts, ratio of tooth size to diameter of part, face width, area of stress pattern, ratio of case depth to tooth size, and hardenability and heat treatment of materials. Size factors have not yet been established for conditions where there is a detrimental size effect, but the factor may be taken as unity for most gears provided that a proper choice of steel is made for the size of the part and its heat treatment and hardening processes.

Load Distribution Factors, C_m and K_m.—The load distribution factor modifies the rating equations to reflect the nonuniform distribution of the load along the lines of contact. The amount of nonuniformity of the load distribution is caused by, and is dependent on the following influences:

1) The gear tooth manufacturing accuracy: lead, profile, and spacing;
2) alignment of the axes of rotation of the pitch cylinders of the mating gear elements;

www.EngineeringEBooksPdf.com

3) elastic deflections of gear unit elements: shafts, bearings, housings, and foundations that support the gear elements;

4) bearing clearances;

5) Hertzian contact and bending deformations at the tooth surface;

6) thermal expansion and distortion due to operating temperature (especially on wide face gearing);

7) centrifugal deflections due to operating speed;

8) tooth crowning and end relief.

Any of these influences that affect a given application should be evaluated by appropriate analysis when possible.

Values for C_m and K_m: The load distribution factor is defined to be the peak load intensity divided by the average, or uniformly distributed load intensity; i.e., the ratio of peak to mean loading. The magnitude is influenced by two components, namely, C_{mf} = face load distribution factor and C_{mt} = transverse load distribution factor that accounts for nonuniform load sharing among load sharing teeth. The load distribution factor is affected primarily by the correctness of the profiles of mating teeth, i.e., profile modification and profile error. The value of the factor may be taken as 1.0 because the Standard has not yet established procedures to evaluate its influence. If C_{mt} is taken as 1.0, then $C_m = K_m = C_{mf}$.

The face load distribution factor C_{mf} accounts for the nonuniform distribution of load across the gearing face width. The magnitude of C_{mf} is defined as the peak load intensity divided by the average load intensity across the face width. Two methods of determining C_{mf} are given in the Standard, an empirical method and an analytical method. These two methods sometimes yield significantly different results.

Empirical Method: The empirical method requires a minimum amount of information and is recommended for relatively stiff designs that meet the following requirements:

1) Ratio of net face width to pinion pitch diameter is less than or equal to 2.0; 2) the gear elements are mounted between bearings (not overhung); 3) face width up to 40 in.; and 4) contact across full face width of narrowest member when loaded.

Other restrictions apply to the use of this method. For details of these restrictions and how the method is applied, the Standard should be consulted.

Analytical Method: This method is based on theoretical calculation of values of elastic tooth deformation under load and lead mismatch. Knowledge of the design, manufacturing, and mounting are required to evaluate the load distribution factor. Calculated results should be compared with past experience as it may be necessary to reevaluate other rating factors to arrive at a rating consistent with past experience. As explained in the Standard, the analytical method assumes that mismatch between the teeth is a straight line. This approach usually yields load distribution factors larger than those used in the past. Another method, using true deflection between the teeth (which is not straight line deflection), has resulted in calculated values closer to those used in the past, but it has not been demonstrated that either method is more accurate. Further study may produce other, more accurate, methods.

In using the analytical method, if high values of the gear tooth stiffness constant are used (G = 2,000,000) or high values of total lead mismatch e_t are assumed, the C_{mf} values calculated will be much more conservative than those obtained by the empirical method. If C_{mf} values calculated are in excess of 2.0, indicating less than full face contact, it may be desirable to revise the design by improving the configuration of bearings, shaft diameters, aspect ratio, and center distance to lower C_{mf}. It may be possible to lower C_{mf} by modifying leads of the parts. The assumed values of e_t and G have a large effect on C_{mf}, so there are times when experimental verification of C_{mf} may be necessary.

www.EngineeringEBooksPdf.com

The analytical method is valid for any gear design and is recommended for the following conditions:

1) ratio of net face width to pinion pitch diameter, F/D, is equal or greater than 2.0 (for double helical gears the gap is not included in the face width); 2) applications with overhung gear elements; 3) applications with long shafts subject to large deflections or where deflections under load reduce width of contact; and 4) applications where contact does not extend across the full face of narrowest member when loaded.

For designs that have high crowns to centralize tooth contact under deflected conditions, the factors C_m and K_m may be conservatively approximated by this method. For the most commonly encountered condition, contact across the entire face width under normal operating load, the face load distribution factor expressions are

$$\text{for spur gearing:} \quad C_{mf} = 1.0 + \frac{G \times e_t \times F}{2 \times W_t} \tag{24}$$

$$\text{and, for helical gearing:} \quad C_{mf} = 1.0 + \frac{G \times e_t \times Z \times F}{1.8 \times W_t} \tag{25}$$

If the total contact length under normal operating load is less than the face width, the expressions for the load distribution factor are

$$\text{for spur gearing:} \quad C_{mf} = \sqrt{\frac{2.0 \times G \times e_t \times F}{W_t}} \tag{26}$$

$$\text{and, for helical gearing:} \quad C_{mf} = \sqrt{\frac{2.0 \times G \times e_t \times Z \times F}{W_t \times P_b}} \tag{27}$$

where G = tooth stiffness constant, lb/in./in. of face (MPa), the average mesh stiffness of a single pair of teeth in the normal direction. The usual range of this value that is compatible with this analysis is $1.5\text{-}2.0 \times 10^6$ lb/in.^{2} ($1.0\text{-}1.4 \times 10^4$ MPa). The most conservative value is the highest. e_t = total lead mismatch between mating teeth, in loaded condition, in. (mm). Z = length of action in transverse plane, from Equation (17) on page 3309, in. (mm). P_b = transverse base pitch, in. (mm).

The total mismatch, e_t, is a virtual separation between the tooth profiles at the end of the face width which is composed of the static, no load separation plus a component due to the elastic load deformations. This total mismatch is influenced by all the items listed under Load Distribution Factors except the Hertzian contact stress and bending deformations of the gear teeth, which are accounted for by the tooth stiffness constant G. Evaluation of e_t, is difficult but it is critical to the reliability of the analytical method. An iterative computer program may be used, but in critical applications full scale testing may be desirable.

Allowable Stress Numbers, S_{ac} and S_{at}.—The allowable stress numbers depend on 1) material composition and cleanliness; 2) mechanical properties; 3) residual stress; 4) hardness and; and 5) type of heat treatment, surface or through hardened.

An allowable stress number for unity application factor, 10 million cycles of load application, 99 per cent reliability and unidirectional loading, is determined or estimated from laboratory and field experience for each material and condition of that material. This stress number is designated S_{ac} and S_{at}.The allowable stress numbers are adjusted for design life cycles by the use of life factors.

The allowable stress numbers for gear materials vary with material composition, cleanliness, quality, heat treatment, and processing practices. For materials other than steel, a range is shown, and the lower values should be used for general design purposes. Data for materials other than steel are given in the Standard.

www.EngineeringEBooksPdf.com

Allowable stress numbers for steel gears are established by specific quality control requirements for each material type and grade. All requirements for the quality grade must be met in order to use the stress values for that grade. Details of these quality requirements are given in the Standard.

Reverse Loading: For idler gears and other gears where the teeth are completely reverse loaded on every cycle, 70 per cent of the S_{at} values should be used.

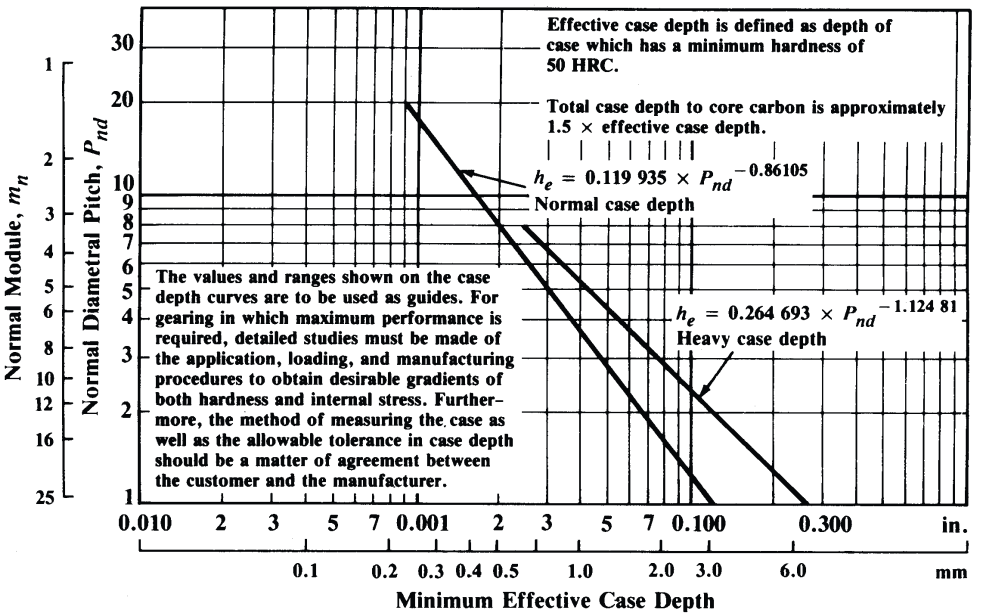

Fig. 4. Effective Case Depth for Carburized Gears, h_e

Case Depth of Surface-Hardened Gears.—The Standard provides formulas to guide the selection of minimum effective case depth at the pitchline for carburized and induction hardened teeth based on the maximum shear from contact loading.

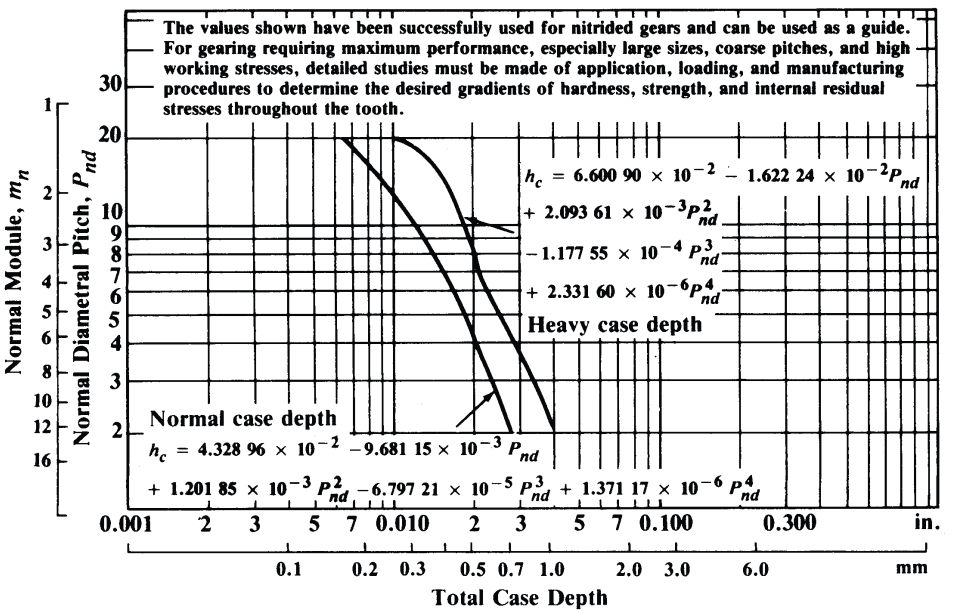

Fig. 5. Minimum Total Case Depth for Nitrided Gears, h_c

www.EngineeringEBooksPdf.com

Fig. 5 shows values that have a long history of successful use for carburized gears and can be used for such gears.

For nitrided gears, case depth is specified as the total case depth h_c, which is defined as the depth below the surface at which the hardness has dropped to110 per cent of the core hardness. Minimum total case depths for nitrided gears are shown in Fig. 5.

Momentary Overloads.—When the gear is subjected to less than 100 cycles of momentary overloads, the maximum allowable stress is determined by the allowable yield properties rather than the bending fatigue strength of the material. Fig. 6 shows suggested values of the allowable yield strength S_{ay} for through hardened steel. For case hardened gears, the core hardness should be used in conjunction with the table of metallurgical factors affecting the bending stress number for carburized gears shown in the Standard.

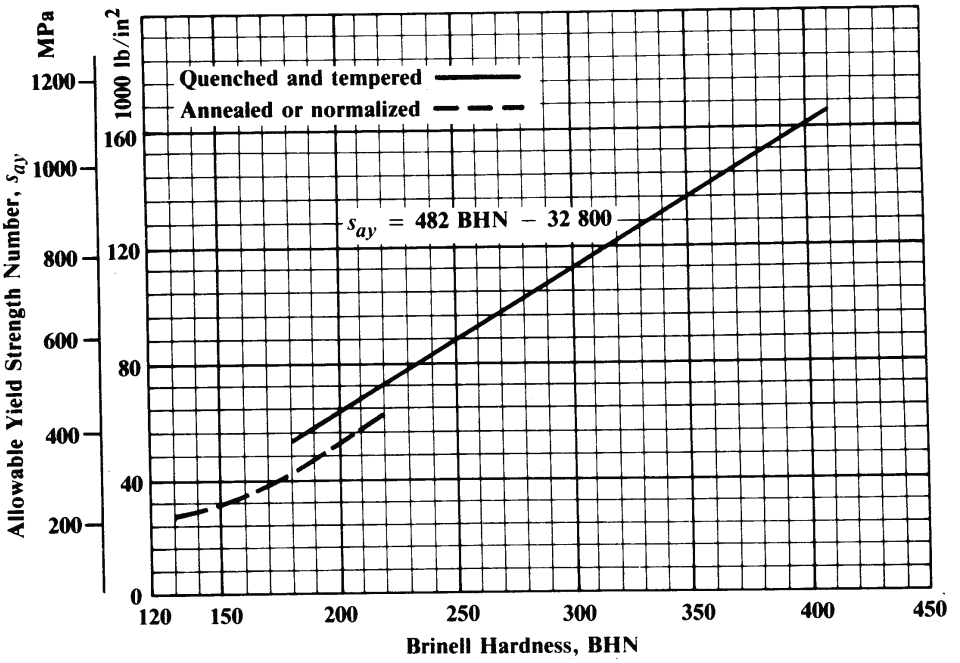

Fig. 6. Allowable Yield Strength Number for Steel Gears, S_{ay}

The design should be checked to make sure that the teeth are not permanently deformed. Also, when yield is the governing stress, the stress correction factor K_f is considered ineffective and therefore taken as unity.

Yield Strength.—For through hardened gears up to 400 BHN, a yield strength factor K_y can be applied to the allowable yield strength taken from Fig. 6. This factor is applied at the maximum peak load to which the gear is subjected:

$$S_{ay \times K_y} \geq \frac{W_{max} \times K_a}{K_v} \frac{P_d}{F} \frac{K_s \times K_m}{J \times K_f} \tag{28}$$

$$S_{ay \times K_y} \geq \frac{W_{max} \times K_a \times K_s \times K_m}{K_v \times F \times m \times J \times K_f} \tag{28a}$$

For conservative practice, K_y is taken as 0.5 and for industrial practice, K_y is 0.75.

Hardness Ratio Factor C_H.—The hardness ratio factor depends on (1) gear ratio and (2) Brinell hardness numbers of gear and pinion. When the pinion is substantially harder than the gear, the work hardening effect increases the gear capacity. Typical values of the hard-

www.EngineeringEBooksPdf.com

ness ratio factor, C_H, for through hardened gears are shown in Fig. 7. These values apply to the gear only, not to the pinion.

When surface hardened pinions (48 HRC or harder) are run with through hardened gears (180-400 BHN), a work hardening effect is achieved. The C_H factor varies with the surface finish of the pinion, K_p and the mating gear hardness as shown in Fig. 8.

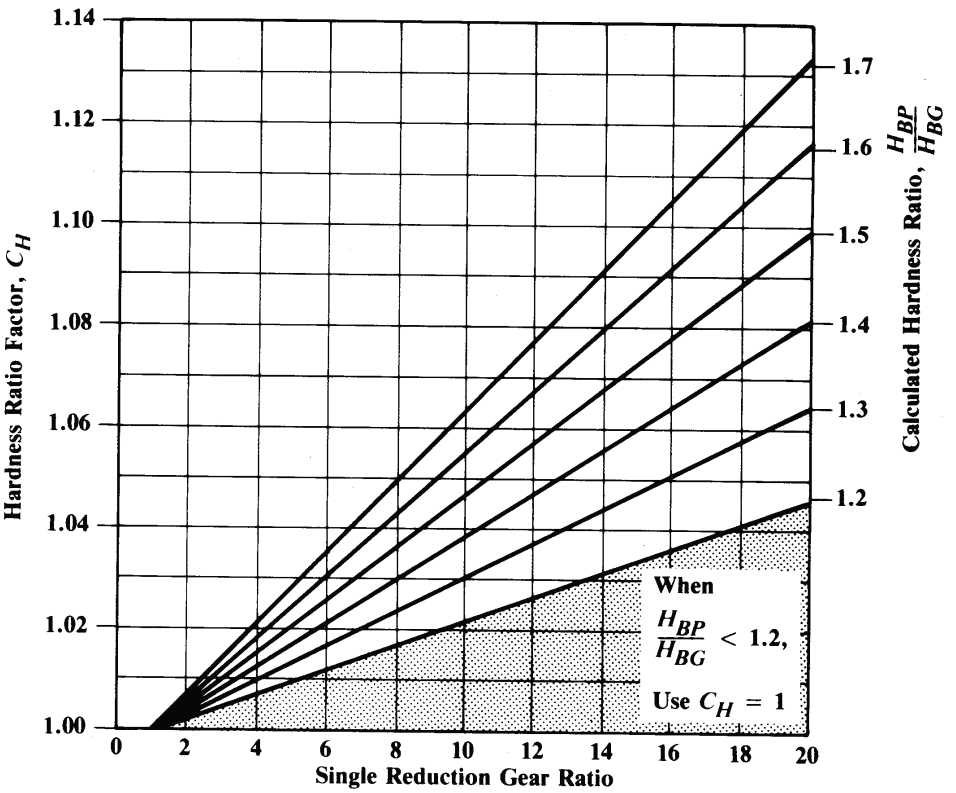

Fig. 7. Hardness Ratio Factor, C_H (Through Hardened)

Life Factors C_L and K_L.— These life factors adjust the allowable stress numbers for the required number of cycles of operation. In the Standard, the number of cycles, N, is defined as the number of mesh contacts under load of the gear tooth being analyzed. Allowable stress numbers are established for 10,000,000 tooth load cycles at 99 per cent reliability. The life cycle factors adjust the allowable stress numbers for design lives other than 10,000,000 cycles.

The life factor accounts for the *S/N* characteristics of the gear material as well as for the gradually increased tooth stress that may occur from tooth wear, resulting in increased dynamic effects and from shifting load distributions that may occur during the design life of the gearing. A C_L or K_L value of 1.0 may be used beyond 10,000,000 cycles, where justified by experience.

Life Factors for Steel Gears: Insufficient data exist to provide accurate life curves for every gear and gear application. However, experience suggests life curves for pitting and strength of steel gears are as shown in Figs. 9 and 10. These figures do not include data for nitrided gears. The upper portions of the shaded zones are for general commercial applications. The lower portions of the shaded zones are typically used for critical service applications where little pitting and tooth wear are permissible and where smoothness of operation and low vibration levels are required. When gear service ratings are established by the use

www.EngineeringEBooksPdf.com

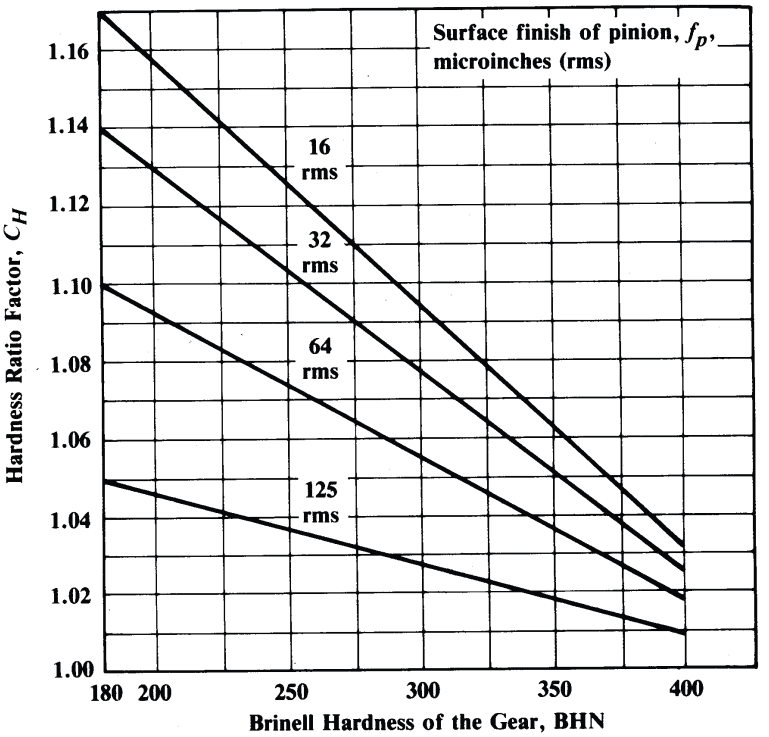

Fig. 8. Hardness Ratio Factor, C_H (Surface Hardened Pinions)

of service factors, life factors C_L and K_L should be set equal to 1.0 for the determination of the gear tooth rating.

Localized Yielding.—If the product of $S_{at} K_L$ exceeds the allowable yield stress S_{ay} of Fig. 6, localized yielding of the teeth may occur. In some applications this yielding is not acceptable. In others, where profile and motion transmission accuracies are not critical, the yielding may be acceptable for limited life.

Reliability Factors, C_R and K_R.—These reliability factors account for the effect of the normal statistical distribution of failures found in materials testing. The allowable stress numbers given in the tables in the Standard are based on a statistical probability of 1 failure in 100 at 10,000,000 cycles. Table 2 contains reliability factors which may be used to modify these allowable stresses to change that probability. These numbers are based on data developed for bending and pitting failure by the U.S. Navy. Other values may be used if specific data are available.

When strength rating is based on yield strength, S_{ay} the values of K_y given in the paragraph, Yield Strength, should be used instead of K_R.

Temperature Factors C_T and K_T.—The temperature factor is generally taken as 1 when gears operate with temperatures of oil or gear blank not over 250°F (120°C). At temperatures above 250°F, the factors are given a value greater than 1.0 to allow for the effect of temperature on oil film and material properties. Consideration must be given to the loss of hardness and strength of some materials due to the tempering effect of temperatures over 350°F (175°C).

www.EngineeringEBooksPdf.com

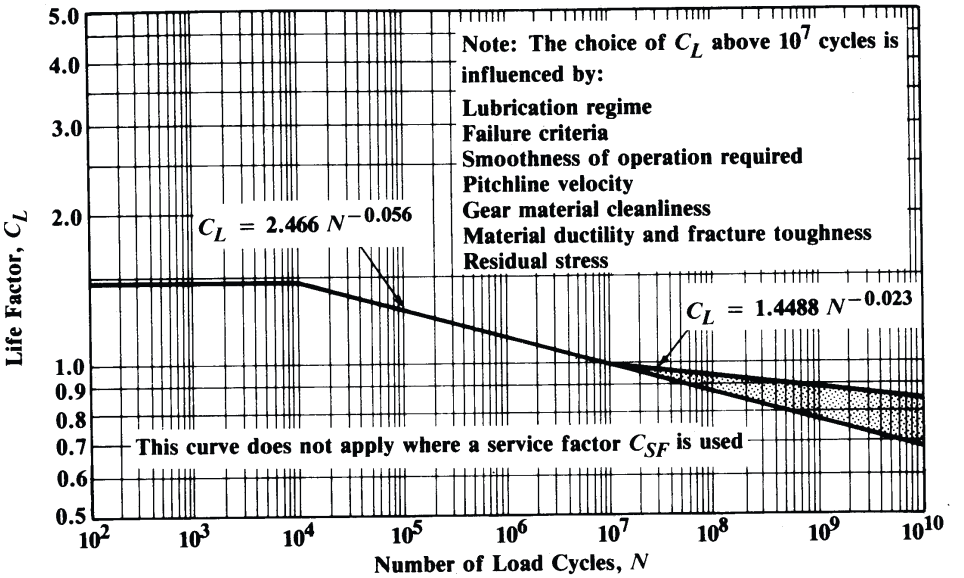

Fig. 9. Pitting Resistance Life Factor, C_L

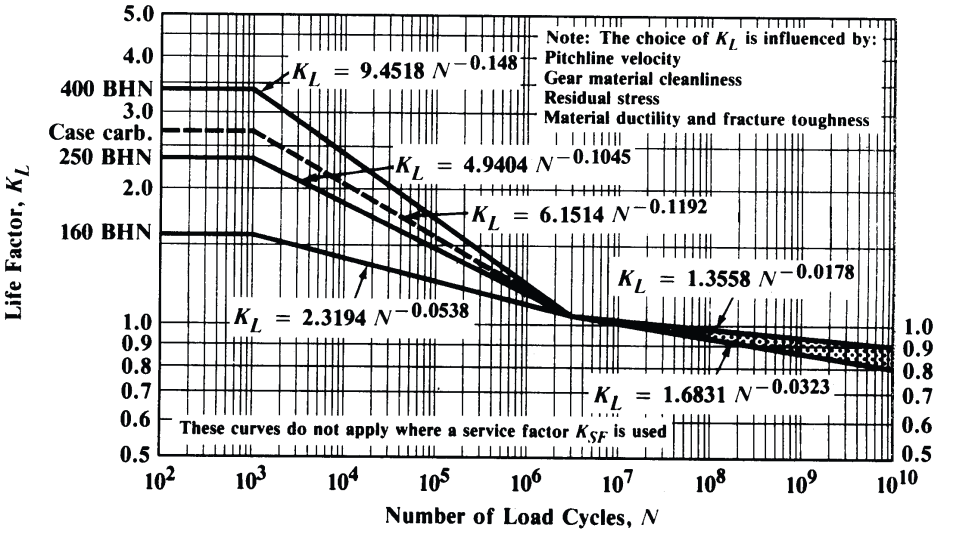

Fig. 10. Bending Strength Life Factor, K_L

Table 2. Reliability Factors, C_R and K_R

Requirement of Application	C_R, K_R[a]	Requirement of Application	C_R, K_R
Fewer than 1failure in 10,000	1.50	Fewer than 1failure in 100	1.00
Fewer than 1failure in 1,000	1.25	Fewer than 1failure in 10	0.85[b]

[a] Tooth breakage is sometimes considered a greater hazard than pitting. In such instances a value of K_R greater than C_R is selected.

[b] At this value plastic flow might occur rather than pitting.

www.EngineeringEBooksPdf.com

Worm Gearing

Worm-Gear Applications.—Worm gearing is employed for transmitting motion between two shafts which are at right angles to each other but which are not in the same plane. Strictly speaking, worm gearing is, therefore, a modified form of spiral or helical gearing, in which one gear takes the form of a screw or worm provided with threads, and the other of a gear with teeth inclined at the same angle as the threads in the worm.

Worm gearing may be employed (1) as an efficient, steady transmitter of power; (2) when a large reduction in velocity is desired; (3) when considerable increase in "mechanical advantage" is required, or, in other words, when a given applied force must overcome a comparatively high resistance to motion. Many worm-gears of the higher ratios are self-locking but very inefficient. Such gears, however, usually are applied to intermittent service, or where the waste of power due to the decreased efficiency of self-locking worm gearing is of little or no importance. The best material for worm gearing is hard phosphor-bronze for the worm-wheel and hardened steel for the worm. The next best materials are cast iron for the worm-wheel and hardened steel or cast iron for the worm. Steel or steel castings for both the worm-wheel and worm are only allowable for slow speeds. The teeth in the worm-wheel and the thread on the worm should always be cut, whenever the gearing is to be used steadily or at a reasonably high speed.

Worm Gearing Classification.—Worm gearing may be divided into two general classes, fine-pitch worm gearing, and coarse-pitch worm gearing. Fine-pitch worm gearing is segregated from coarse-pitch worm gearing for the following reasons:

1) Fine-pitch worms and wormgears are used largely to transmit motion rather than power. Tooth strength except at the coarser end of the fine-pitch range is seldom an important factor; durability and accuracy, as they affect the transmission of uniform angular motion, are of greater importance.

2) Housing constructions and lubricating methods are, in general, quite different for fine-pitch worm gearing.

3) Because fine-pitch worms and wormgears are so small, profile deviations and tooth bearings cannot be measured with the same accuracy as can those of coarse pitches.

4) Equipment generally available for cutting fine-pitch wormgears has restrictions which limit the diameter, the lead range, the degree of accuracy attainable, and the kind of tooth bearing obtainable.

5) Special consideration must be given to top lands in fine-pitch hardened worms and wormgear-cutting tools.

6) Interchangeability and high production are important factors in fine-pitch worm gearing; individual matching of the worm to the gear, as often practiced with coarse-pitch precision worms, is impractical in the case of fine-pitch worm drives.

American Standard Design for Fine-pitch Worm Gearing (ANSI B6.9-1977).—This standard is intended as a design procedure for fine-pitch worms and wormgears having axes at right angles. It covers cylindrical worms with helical threads, and wormgears hobbed for fully conjugate tooth surfaces. It does not cover helical gears used as wormgears.

Hobs: The hob for producing the gear is a duplicate of the mating worm with regard to tooth profile, number of threads, and lead. The hob differs from the worm principally in that the outside diameter of the hob is larger to allow for resharpening and to provide bottom clearance in the wormgear.

Pitches: Eight standard axial pitches have been established to provide adequate coverage of the pitch range normally required: 0.030, 0.040, 0.050, 0.065, 0.080, 0.100, 0.130, and 0.160 inch.

www.EngineeringEBooksPdf.com

Axial pitch is used as a basis for this design standard because: 1) Axial pitch establishes lead which is a basic dimension in the production and inspection of worms; 2) the axial pitch of the worm is equal to the circular pitch of the gear in the central plane; and 3) only one set of change gears or one master lead cam is required for a given lead, regardless of lead angle, on commonly-used worm-producing equipment.

Lead Angles: Fifteen standard lead angles have been established to provide adequate coverage: 0.5, 1, 1.5, 2, 3, 4, 5, 7, 9, 11, 14, 17, 21, 25, and 30 degrees.

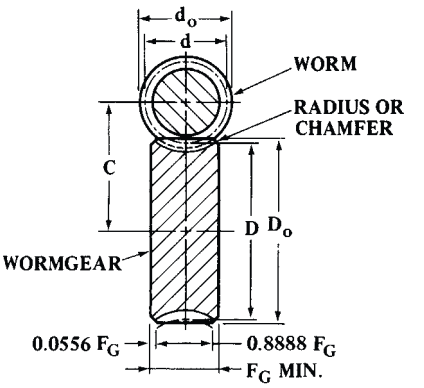
This series of lead angles has been standardized to: 1) Minimize tooling; 2) permit obtaining geometric similarity between worms of different axial pitch by keeping the same lead angle; and 3) take into account the production distribution found in fine-pitch worm gearing applications.

For example, most fine-pitch worms have either one or two threads. This requires smaller increments at the low end of the lead angle series. For the less frequently used thread numbers, proportionately greater increments at the high end of the lead angle series are sufficient.

Table 1. Formulas for Proportions of American Standard Fine-pitch Worms and Wormgears *ANSI B6.9-1977*

LETTER SYMBOLS

P = Circular pitch of wormgear
P = axial pitch of the worm, P_x, in the central plane
P_x = Axial pitch of worm
P_n = Normal circular pitch of worm and wormgear = $P_x \cos \lambda = P \cos \psi$
λ = Lead angle of worm
ψ = Helix angle of wormgear
n = Number of threads in worm
N = Number of teeth in wormgear
$N = nm_G$
m_G = Ratio of gearing = $N \div n$



Item	Formula	Item	Formula
WORM DIMENSIONS		WORMGEAR DIMENSIONS[a]	
Lead	$l = nP_x$	Pitch Diameter	$D = NP \div \pi = NP_x \div \pi$
Pitch Diameter	$d = l \div (\pi \tan \lambda)$	Outside Diameter	$D_o = 2C - d + 2a$
Outside Diameter	$d_o = d + 2a$	Face Width	$F_{G\min} = 1.125 \times \sqrt{(d_o + 2c)^2 - (d_o - 4a)^2}$
Safe Minimum Length of Threaded Portion of Worm[b]	$F_W = \sqrt{D_o^2 - D^2}$		
DIMENSIONS FOR BOTH WORM AND WORMGEAR			
Addendum	$a = 0.3183P_n$	Tooth thickness	$t_n = 0.5P_n$
Whole Depth	$h_t = 0.7003P_n + 0.002$	Approximate normal pressure angle[c]	$\phi_n = 20$ degrees
Working Depth	$h_k = 0.6366P_n$		
Clearance	$c = h_t - h_k$	Center distance	$C = 0.5\,(d + D)$

www.EngineeringEBooksPdf.com

[a] Current practice for fine-pitch worm gearing does not require the use of throated blanks. This results in the much simpler blank shown in the diagram which is quite similar to that for a spur or helical gear. The slight loss in contact resulting from the use of non-throated blanks has little effect on the load-carrying capacity of fine-pitch worm gears. It is sometimes desirable to use topping hobs for producing wormgears in which the size relation between the outside and pitch diameters must be closely controlled. In such cases the blank is made slightly larger than D_o by an amount (usually from 0.010 to 0.020) depending on the pitch. Topped wormgears will appear to have a small throat which is the result of the hobbing operation. For all intents and purposes, the throating is negligible and a blank so made is not to be considered as being a throated blank.

[b] This formula allows a sufficient length for fine-pitch worms.

[c] As stated in the text on page 3323, the actual pressure angle will be slightly greater due to the manufacturing process.

All dimensions in inches unless otherwise indicated.

Pressure Angle of Worm: A pressure angle of 20 degrees has been selected as standard for cutters and grinding wheels used to produce worms within the scope of this Standard because it avoids objectionable undercutting regardless of lead angle.

Although the pressure angle of the cutter or grinding wheel used to produce the worm is 20 degrees, the normal pressure angle produced in the worm will actually be slightly greater, and will vary with the worm diameter, lead angle, and diameter of cutter or grinding wheel. A method for calculating the pressure angle change is given under the heading *Effect of Production Method on Worm Profile and Pressure Angle*.

Pitch Diameter Range of Worms: The minimum recommended worm pitch diameter is 0.250 inch and the maximum is 2.000 inches.Pitch diameters for all possible combinations of lead and lead angle, together with the number of threads for each lead, are given in Table 2a and 2b.

Tooth Form of Worm and Wormgear: The shape of the worm thread in the normal plane is defined as that which is produced by a symmetrical double-conical cutter or grinding wheel having straight elements and an included angle of 40 degrees.

Because worms and wormgears are closely related to their method of manufacture, it is impossible to specify clearly the tooth form of the wormgear without referring to the mating worm. For this reason, worm specifications should include the method of manufacture and the diameter of cutter or grinding wheel used. Similarly, for determining the shape of the generating tool, information about the method of producing the worm threads must be given to the manufacturer if the tools are to be designed correctly.

The worm profile will be a curve that departs from a straight line by varying amounts, depending on the worm diameter, lead angle, and the cutter or grinding wheel diameter. A method for calculating this deviation is given in the Standard. The tooth form of the wormgear is understood to be made fully conjugate to the mating worm thread.

Proportions of Fine-pitch Worms and Wormgears.—Hardened worms and cutting tools for wormgears should have adequate top lands. To automatically provide sufficient top lands, regardless of lead angle or axial pitch, the addendum and whole depth proportions of fine-pitch worm gearing are based on the normal circular pitch. Tooth proportions based on normal pitch for all combinations of standard axial pitches and lead angles are given in Table 3. Formulas for the proportions of worms and worm gears are given in Table 1.

Example 1: Determine the design of a worm and wormgear for a center distance of approximately 3 inches if the ratio is to be 10 to 1; axial pitch, 0.1600 inch; and lead angle, 30 degrees.

From Table 2a and 2b it can be determined that there are eight possible worm diameters that will satisfy the given conditions of lead angle and pitch. These worms have from 3 to 10 threads.

www.EngineeringEBooksPdf.com

To satisfy the 3-inch center distance requirement it is now necessary to determine which of these eight worms, together with its mating wormgear, will come closest to making up this center distance. One way of doing this is as follows:

First use the formula given below to obtain the approximate number of threads necessary. Then from the eight possible worms in Table 2a and 2b, choose the one whose number of threads is nearest this approximate value:

Approximate number of threads needed for required center distance =

$$\frac{2\pi \times \text{ required center distance}}{P_x(\cot\lambda + m_G)} = \frac{2 \times 3.1416 \times 3}{0.1600 \times (1.7320 + 10)} = 10.04 \text{ threads}$$

Of the eight possible worms in Table 2a and 2b, the one having a number of threads nearest this value is the 10-thread worm with a pitch diameter of 0.8821 inch. Since the ratio of gearing is given as 10, N may now be computed as follows: $N = 10 \times 10 = 100$ teeth (from Table 1)

Other worm and wormgear dimensions may now be calculated using the formulas given in Table 1 or may be taken from the data presented in Table 2a, 2b, and 3.

$l = 1.600$ inches (from Table 2b)

$d = 0.8821$ inch (from Table 2b)

$D = 100 \times 0.1600 + 3.1416 = 5.0930$ inches (from Table 1)

$C = 0.5(0.8821 + 5.0930) = 2.9876$ inches (from Table 1)

$P_n = 0.1386$ inch (from Table 3)

$a = 0.0441$ inch (from Table 3)

$h_t = 0.0990$ inch (from Table 3)

$h_k = 0.6366 \times 0.1386 = 0.0882$ inch (from Table 1)

$c = 0.0990 - 0.0882 = 0.0108$ inch (from Table 1)

$t_n = 0.5 \times 0.1386 = 0.0693$ inch (from Table 1)

$d_0 = 0.8821 + (2 \times 0.0441) = 0.9703$ inch (from Table 1)

$D_0 = (2 \times 2.9876) - 0.8821 + (2 \times 0.0441) = 5.1813$ (from Table 1)

$$F_G = 1.125\sqrt{(0.9703 + 2 \times 0.0108)^2 - (0.9703 - 4 \times 0.0441)^2} = 0.6689 \text{ inch}$$

$$F_W = \sqrt{5.1813^2 - 5.0930^2} = 0.9525 \text{ inch}$$

Example 2: Determine the design of a worm and wormgear for a center distance of approximately 0.550 inch if the ratio is to be 50 to 1 and the axial pitch is to be 0.050 inch.

Assume that $n = 1$ (since most fine-pitch worms have either one or two threads). The lead of the worm will then be $nP_x = 1 \times 0.050 = 0.050$ inch. From Table 2a and 2b it can be determined that there are six possible lead angles and corresponding worm diameters that will satisfy this lead. The approximate lead angle required to meet the conditions of the example can be computed from the following formula:

$$\text{Cotangent of approx. lead angle} = \frac{2\pi \times \text{ approximate center distance required}}{\text{assumed number of threads} \times \text{ axial pitch}} - m_G$$

Using letter symbols, this formula becomes:

$$\cot\lambda = \frac{2\pi \times C}{n \times P_x} - m_G = \frac{2 \times 3.1416 \times 0.550}{1 \times 0.050} - 50 = 19.1152$$

$$\lambda = 2°59'$$

Of the six possible worms in Table 2a and 2b, the one with the 3-degree lead angle is closest to the calculated 2°59′ lead angle. This worm, which has a pitch diameter of 0.3037

www.EngineeringEBooksPdf.com

inch, is therefore selected.The remaining worm and wormgear dimensions may now be determined from the data in Table 2a, 2b, and 3 and by use of the formulas given in Table 1.

$N = 50 \times 1 = 50$ teeth (from Table 1)

$d = 0.3037$ inch (from Table 2b)

$D = 50 \times 0.050 \div 3.1416 = 0.7958$ inch (from Table 1)

$C = 0.5(0.3037 + 0.7958) = 0.5498$ inch (from Table 1)

$P_n = 0.0499$ inch (from Table 3)

$a = 0.0159$ inch (from Table 3)

$h_t = 0.0370$ inch (from Table 3)

$h_k = 0.6366 \times 0.0499 = 0.0318$ inch (from Table 1)

$c = 0.0370 - 0.0318 = 0.0052$ inch (from Table 1)

$t_n = 0.5 \times 0.0499 = 0.0250$ inch (from Table 1)

$d_0 = 0.3037 + (2 \times 0.0159) = 0.3355$ inch (from Table 1)

$D_0 = (2 \times 0.5498) - 0.3037 + (2 \times 0.0159) = 5.1813$ (from Table 1)

$$F_{G\min} = 1.125\sqrt{(0.3355 + 2 \times 0.0052)^2 - (0.3355 - 4 \times 0.0159)^2} = 0.2405 \text{ inch (from Table 1)}$$

$$F_W = \sqrt{0.8277^2 - 0.7958^2} = 0.2276 \text{ inch (from Table 1)}$$

Effect of Production Method on Worm Profile and Pressure Angle.—In worm gearing, tooth bearing is usually used as the means of judging tooth profile accuracy since direct profile measurements on fine-pitch worms or wormgears is not practical. According to AGMA 370.01, Design Manual for Fine-Pitch Gearing, a minimum of 50 per cent initial area of contact is suitable for most fine-pitch worm gearing, but in some cases, such as when the load fluctuates widely, a more restricted initial area of contact may be desirable.

Except where single-pointed lathe tools, end mills, or cutters of special shape are used in the manufacture of worms, the pressure angle and profile produced by the cutter are different from those of the cutter itself. The amounts of these differences depend on several factors, namely, diameter and lead angle of the worm, thickness and depth of the worm thread, and diameter of the cutter or grinding wheel. Fig. 1 shows the curvature and pressure angle effects produced in the worm by cutters and grinding wheels, and how the amount of variation in worm profile and pressure angle is influenced by the diameter of the cutting tool used.

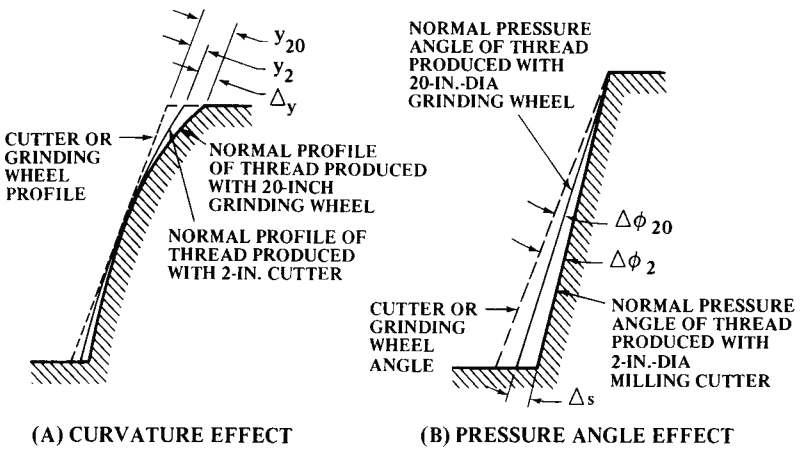


Fig. 1. Effect of Diameter of Cutting on Profile and Pressure Angle of Worms

Calculating Worm Deviations and Pressure Angle Changes.—Included in American Standard ANSI B6.9-1977 is an extensive tabulation of profile deviations and pressure angle changes produced by cutters and grinding wheels of 2-inch and 20-inch diameters. These diameters represent the limits of the range commonly used, and the data given are useful in specifying worm profile tolerances. The data also aid in the selection of the method to be used in producing the worm and in specifying the hobs for wormgears. The formulas used to compute the data in the Standard are given here in slightly modified form, and may be used to calculate the profile deviations and pressure angle changes produced in the worm by cutters or grinding wheels.

$$\rho_{ni} = \frac{r\sin\phi_n}{(\sin\lambda)^2} \text{ inches} \tag{1}$$

$$\rho_n = \rho_{ni} + \frac{r\rho_{ni}}{R(\cos\lambda)^2} \text{ inches} \tag{2}$$

$$\Delta\phi = \frac{5400r(\sin\lambda)^3}{n(R(\cos\lambda)^2 + r)} \text{ minutes} \tag{3}$$

$$q = a\sec\phi_n \text{ inches} \tag{4}$$

$$y = \frac{q^2}{2\rho_n} \text{ inches} \tag{5}$$

$$s = 0.000582q\Delta\phi \text{ inches} \tag{6}$$

$$\Delta y = y_w - y_c \text{ inches} \tag{7}$$

$$\Delta s = s_c - s_w \text{ inches} \tag{8}$$

In these formulas,

ρ_{ni} = radius of curvature of normal thread profile for involute thread;

r = pitch radius of worm;

Φ_n = normal pressure angle of cutter or grinding wheel;

λ = lead angle of worm;

ρ_n = radius of curvature of normal thread profile;

R = radius of cutter or grinding wheel;

$\Delta\Phi$ = difference between the normal pressure angle of the thread and the normal pressure angle of the cutter or grinding wheel in minutes (see diagram). Subscripts c and w are used to denote the cutter and grinding wheel diameters, respectively;

n = number of threads in worm;

a = addendum of worm;

q = slant height of worm addendum;

y = amount normal worm profile departs from a straight side (see diagram). Subscripts c and w are used to denote the cutter and grinding wheel diameters, respectively;

s = effect along slant height of worm thread caused by change in pressure angle $\Delta\Phi$

Δy = difference in y values of two cutters or grinding wheels of different diameter (see diagram);

Δs = effect of $\Delta\Phi_c - \Delta\Phi_w$ along slant height of thread (see diagram).

www.EngineeringEBooksPdf.com

Example 3: Assuming the worm dimensions are the same as in Example 1, determine the corrections for two worms, one milled by a 2-inch diameter cutter, the other ground by a 20-inch diameter wheel, both to be assembled with identical wormgears.

To make identical worms when using a 2-inch cutter and a 20-inch wheel, the pressure angle of either the cutter or the wheel must be corrected by an amount corresponding to Δs and the profile of the cutter or wheel must be a curve which departs from a straight line by an amount Δy. The calculations are as follows:

For the 2-inch diameter cutter, using Formula (1) to (6),

$$\rho_{ni} = \frac{0.4410 \times 0.3420}{0.5000^2} = 0.6033 \text{ inch} \quad (1)$$

$$\rho_n = 0.6033 + \frac{0.4410 \times 0.6033}{1 \times 0.8660^2} = 0.9581 \text{ inch} \quad (2)$$

$$\Delta\phi_c = \frac{5400 \times 0.4410 \times 0.5000^3}{10(1 \times 0.8660^2 + 0.4410)} = 24.99 \text{ inches} \quad (3)$$

$$q = 0.0441 \times 1.0642 = 0.0469 \text{ inch} \quad (4)$$

$$y_c = \frac{0.0469^2}{2 \times 0.6387} = 0.00172 \text{ inches} \quad (5)$$

$$s_c = 0.000582 \times 0.0469 \times 24.99 = 0.000682 \text{ inch} \quad (6)$$

For the 20-inch diameter wheel, using Formula (1) to (6)

$$\rho_{ni} = \frac{0.4410 \times 0.3420}{0.5000^2} = 0.6033 \text{ inch} \quad (1)$$

$$\rho_n = 0.6033 + \frac{0.4410 \times 0.6033}{10 \times 0.8660^2} = 0.6387 \text{ inch} \quad (2)$$

$$\Delta\phi_w = \frac{5400 \times 0.4410 \times 0.5000^3}{10(10 \times 0.8660^2 + 0.4410)} = 3.749 \text{ inches} \quad (3)$$

$$q = 0.0441 \times 1.0642 = 0.0469 \text{ inch} \quad (4)$$

$$y_w = \frac{0.0469^2}{2 \times 0.6387} = 0.00172 \text{ inches} \quad (5)$$

$$s_w = 0.000582 \times 0.0469 \times 3.749 = 0.000102 \text{ inch} \quad (6)$$

Applying Formula (7) to (8):

$$\Delta y = 0.00172 - 0.00115 = 0.00057 \text{ inch} \quad (7)$$

$$\Delta s = 0.000682 - 0.000102 = 0.000580 \text{ inch} \quad (8)$$

Therefore the pressure angle of either the cutter or the wheel must be corrected by an amount corresponding to a Δs of 0.00580 inch and the profile of the cutter or wheel must be a curve which departs from a straight line by 0.00057 inch.

Industrial Worm Gearing.—The primary considerations in industrial worm gearing are usually:

1) To transmit power efficiently; 2) to transmit power at a considerable reduction in velocity; and 3) to provide a considerable "mechanical advantage" when a given applied force must overcome a comparatively high resisting force.

www.EngineeringEBooksPdf.com

Worm gearing for use in such applications is usually of relatively coarse pitch. The notation in the table that follows is used in the formulas on the following pages.

Notation for Worm Gearing

a	addendum, worm thread	m	module = 0.3183 × axial pitch
A	addendum, wormgear tooth	N	revolutions per minute of wormgear
B	dedendum, wormgear tooth	n	revolutions per minute of worm
b	dedendum, worm thread	P	axial pitch of worm and circular pitch of wormgear
C	center distance (Fig. 2, page 3335)	P_n	normal pitch of worm
c	clearance	Q	arc length of wormgear tooth measured along root
D	pitch diameter of wormgear	R	ratio of worm gearing = No. of wormgear teeth ÷ No. of worm threads.
d	pitch diameter of worm	S_c	surface stress factor (Table 4)
d_0	outside diameter of worm	S_b	bending stress factors, lbs. per sq. in. (Table 4)
D_0	outside or over-all diameter of wormgear	T	number of teeth on wormgear
D_t	throat diameter of wormgear	t	number of threads or “starts” and on worm-2 for double thread, 3 for triple thread, 4 for quadruple thread, etc.
E	efficiency of worm gearing, per cent	U	radius of wormgear throat (Fig. 2)
F	nominal face width of wormgear rim	V	rubbing speed of worm in feet per minute
F_e	effective face width (Fig. 2, p. 1928)	W	whole tooth depth (worm and-wormgear)
f	coefficient of friction	X_{cp} and X_{cw}	speed factor when load rating is limited by wear (Fig. 2)
G	length of worm threaded section	X_{bp} and X_{bw}	speed factor when load rating is limited by strength (Table 5)
H	horsepower rating	ϕ	angle of friction (tan ϕ = coeffi- cient of friction)
L	lead of worm thread = pitch × number of threads or “starts”		
L_a	lead angle of worm = helix angle measured from a plane perpendicular to worm axis		
M	torque applied to wormgear, pound inches		

Materials for Worm Gearing.—Worm gearing, especially for power transmission, should have steel worms and phosphor bronze wormgears. This combination is used extensively. The worms should be hardened and ground to obtain accuracy and a smooth finish.

The phosphor bronze wormgears should contain from 10 to 12 per cent of tin. The S.A.E. phosphor gear bronze (No. 65) contains 88-90% copper, 10-12% tin, 0.50% lead, 0.50% zinc (but with a maximum total lead, zinc and nickel content of 1.0 percent), phosphorous 0.10-0.30%, aluminum 0.005%. The S.A.E. nickel phosphor gear bronze (No. 65 + Ni) contains 87% copper, 11% tin, 2% nickel and 0.2% phosphorous.

Single-thread Worms.—The ratio of the worm speed to the wormgear speed may range from 1.5 or even less up to 100 or more. Worm gearing having high ratios are not very effi-

www.EngineeringEBooksPdf.com

cient as transmitters of power; nevertheless high as well as low ratios often are required. Since the ratio equals the number of wormgear teeth divided by the number of threads or "starts" on the worm, single-thread worms are used to obtain a high ratio. As a general rule, a ratio of 50 is about the maximum recommended for a single worm and wormgear combination, although ratios up to 100 or higher are possible. When a high ratio is required, it may be preferable to use, in combination, two sets of worm gearing of the multi-thread type in preference to one set of the single-thread type in order to obtain the same total reduction and a higher combined efficiency.

Single-thread worms are comparatively inefficient because of the effect of the low lead angle, see *Efficiency of Worm Gearing*, page 3337; consequently, single-thread worms are not used when the primary purpose is to transmit power as efficiently as possible but they may be employed either when a large speed reduction with one set of gearing is necessary, or possibly as a means of adjustment, especially if "mechanical advantage" or self-locking are important factors.

Multi-thread Worms.—When worm gearing is designed primarily for transmitting power efficiently, the lead angle of the worm should be as high as is consistent with other requirements and preferably between, say, 25 or 30 and 45 degrees. This means that the worm must be multi-threaded. To obtain a given ratio, some number of wormgear teeth divided by some number of worm threads must equal the ratio. Thus, if the ratio is 6, combinations such as the following might be used:

$$\frac{24}{4}, \frac{30}{5}, \frac{36}{6}, \frac{42}{7}$$

The numerators represent the number of wormgear teeth and the denominators, the number of worm threads or "starts." The number of wormgear teeth may not be an exact multiple of the number of threads on a multi-thread worm in order to obtain a "hunting tooth" action.

Number of Threads or "Starts" on Worm: The number of threads on the worm ordinarily varies from one to six or eight, depending upon the ratio of the gearing. As the ratio is increased, the number of worm threads is reduced, as a general rule. In some cases, however, the higher of two ratios may also have a larger number of threads. For example, a ratio of $6\frac{1}{5}$ would have 5 threads whereas a ratio of $6\frac{5}{6}$ would have 6 threads. Whenever the ratio is fractional, the number of threads on the worm equals the denominator of the fractional part of the ratio.

Ratio for Obtaining "Hunting Tooth" Action.—In designing wormgears having multi-thread worms, it is common practice to select a number of wormgear teeth that is not an exact multiple of the number of worm threads. To illustrate, if the desired ratio is about 5 or 6, the actual ratio might be $5\frac{1}{6}$, $5\frac{5}{6}$, $5\frac{2}{7}$, $6\frac{1}{5}$, etc., so that combinations such as $\frac{31}{6}$, $\frac{35}{6}$, $\frac{37}{7}$ or $\frac{31}{5}$ would be obtained. Since the number of wormgear teeth and number of worm threads do not have a common divisor, the threads of the worm will mesh with all of the wormgear teeth in succession, thus obtaining a "hunting tooth" or self-indexing action. This progressive change will also occur during the wormgear hobbing operation, and its primary purpose is to produce more accurate wormgears by uniformly distributing among all of the teeth, any slight errors which might exist in the hob teeth. Another object is to improve the "running-in" action between the hardened and ground worm and the phosphor bronze wormgear, but in order to obtain this advantage, the threads on the worm must be accurately or uniformly spaced by precise indexing. With a "hunting tooth ratio," if the thread spacing of a multi-thread worm is inaccurate, load distribution on the threads will be unequal and some threads might not even make contact with the wormgear teeth. For this reason, if the indexing is inaccurate, it is preferable to avoid a hunting tooth ratio, but in that case, if the gearing is disassembled, the same worm and wormgear teeth should be mated when reassembled.

Table 4. Rules and Formulas for Worm Gearing

No.	To Find	Rule	Formula
1	Addendum	Addendum may be affected by lead angle. See paragraph, Addendum and Dedendum.	
2	Center Distance	Add pitch diameter of wormgear to pitch diameter of worm, and divide sum by 2	$C = \frac{D+d}{2}$
3		Divide number of worm threadsby tangent lead angle, add number of wormgear teeth and multiply sum by quotient obtained by dividing pitch by 6.2832	$C = \frac{P}{6.2832}\left(\frac{t}{\tan L_a} + T\right)$
4	Dedendum	Dedendum may be affected by lead angle. See paragraph, *Addendum and Dedendum* on page 3335.	
5	Clearance	British Standard-multiply cosine lead angle by 0.2 times module.	$c = 0.2m\cos L_a$
6	Face Width Wormgear	For single and double thread worms, multiply pitch by 2.38 and add 0.25. (shell type worm.)	$F = 2.38P + 0.25$
7		For triple and quadruple thread multiply pitch by 2.15 and add 0.2. (shell type)	$F = 2.15P + 0.20$
8		When worm threads are integral with shaft, face width of wormgear may be equal $C^{0.875}$ divided by 3.	$F = \frac{C^{0.875}}{3}$
9	Lead of Worm Thread	Multiply pitch by number of worm threads or “starts”	$L = lP$
10		Multiply pitch circumference of worm by tangent of lead angle.	$L = \pi d \times \tan L_a$
11		Divide pitch circumference of wormgear by ratio.	$L = \pi D \div R$
12	Lead Angle, Worm	Divide lead by pitch circumference of worm; quotient is tangent of lead angle.	$\tan L_a = \frac{L}{3.1416d}$
13	Outside Diam., Worm	Add to pitch diameter twice the addendum. see paragraph, pitch diameter of worm; also see *Addendum and Dedendum* on page 3335.	$d_0 = d + 2a$
14	Outside Diam., Wormgear	For outside or over-all diameter of wormgear, see paragraph, outside diameter of wormgear.	
15	Pitch of Worm and Wormgear	Divide lead by number of threads or “starts” on worm = axial pitch of worm and circular pitch of wormgear.	$P = \frac{L}{t}$
16		Subtract the worm pitch diameter from twice the center distance. Multiply by 3.1416 and divide by number of wormgear teeth.	$P = \frac{(2C-d)3.1416}{T}$

www.EngineeringEBooksPdf.com

Table 4. *(Continued)* **Rules and Formulas for Worm Gearing**

No.	To Find	Rule	Formula
17	Pitch of Worm, Normal	Multiply axial pitch by cosine of lead angle to find normal pitch.	$P_n = P \times \cos L_a$
18	Pitch Diameter, Worm	Subtract pitch diameter of worm gear from twice the center distance.	$d = 2C - D$
19		Subtract twice the addendum from outside diameter. See *Addendum and Dedendum*.	$D = d_0 - 2a$
20		Multiply lead by cotangent lead angle and divide product by 3.1416	$d = \frac{L \times \cot L_a}{3.1416}$
21	Pitch Diameter, Wormgear	Subtract pitch diameter of worm from twice the center distance.	$D = 2C - d$
22		Multiply number of wormgear teeth by axial pitch of worm and divide product by 3.1416.	$D = \frac{TP}{3.1416}$
23	Radius of Rim Corner, Wormgear	Multiply pitch by 0.25	Radius $= 0.25P$
24		British Standard: Radius = 0.5 × module.	Radius $= 0.50m$
25	Ratio	Divide number of wormgear teeth by by number of worm threads.	$R = T \div t$
26	Rubbing Speed, Ft. per Minute	Divide wormgear pitch diameter by ratio; square quotient and add to square of worm pitch diameter; multiply square root of this sum by 0.262 × R.P.M. of worm.	$V = 0.262n\sqrt{d^2 + \left(\frac{D}{4}\right)^2}$
27		Multiply 0.262 × Pitch diameter of worm by worm R.P.M. of worm; then multiply product by secant of lead angle.	$V = 0.262dn \times \sec L_a$
28	Throat Diameter Wormgear	Add twice the addendum to pitch diameter. See *Addendum and Dedendum* on page 3335.	$D_t = D + 2A$
29	Throat Radius Wormgear	Subtract twice the addendum from outside radius of worm.	$U = \frac{d_0}{2} - 2a$
30	Total Depth	Whole depth equals addendum + dedendum. See *Addendum and Dedendum* on page 3335.	$W = a + b$ or $A + B$
31	Worm Thread Length	Multiply the number of wormgear teeth by 0.02, add 4.5 and multiply sum by pitch.	$G = P(4.5 + 0.02T)$
32		British Standard subtract square of wormgear pitch diameter from square of outside diameter and extract square root of remainder.	$G = \sqrt{D_0^2 - D^2}$

www.EngineeringEBooksPdf.com

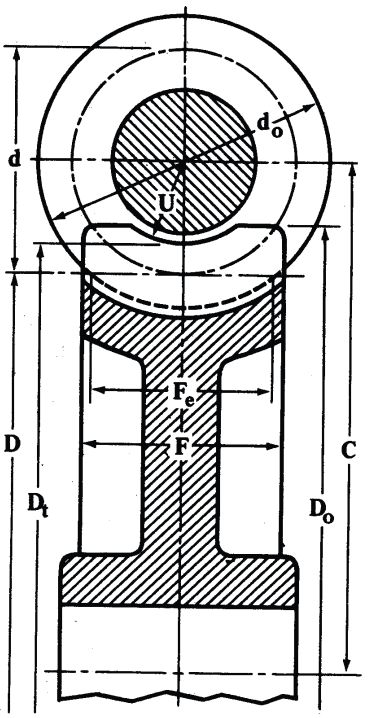

Fig. 2.

Pitch Diameter of Worm.—The worm must be strong enough to transmit its maximum load without excessive deflection but the diameter should be as small as is consistent with the necessary strength in order to minimize the rubbing speed. It is impracticable to give a rule or formula that is generally applicable, but the following empirical rules are based upon actual practice and may prove useful as a general guide. They apply to casehardened alloy steel worms which are integral with the shaft.

For ratios of 5, 6, or 7, the pitch diameter ranges approximately from 0.38 *C* when center distance *C* is 4 inches to 0.33 *C* when *C* is 20 inches.

For ratios of 8, 9,10, the pitch diameter ranges approximately from 0.38 *C* when center distance *C* is 4 inches to 0.25 *C* when *C* is 30 inches.

For ratios of 10 to 20, the pitch diameter ranges approximately from 0.37 *C* when center distance *C* is 4 inches to 0.24 *C* when *C* is 30 inches.

For ratios of 20 to 40, the pitch diameter ranges approximately from 0.36 *C* when center distance *C* is 4 inches to 0.23 *C* when C is 30 inches.

According to another empirical formula pitch diameter $d = C^{0.75} + 2.2$.

Addendum and Dedendum.—The following A.G.M.A. formulas are applicable to industrial worm gearing. For single and double thread worms, addendum $a = 0.318\ P$ and whole depth $W = 0.686\ P$; for triple and quadruple threads, addendum $a = 0.286\ P$ and whole depth $W = 0.623\ P$.

According to the British standard, a = module; $m = 0.3183\ P$; $b = m(2.2 \cos L_a - 1)$; $A = m(2.2 \cos L_a - 1)$; $B = m(1 + 0.2 \cos L_a)$.

Outside Diameter of Wormgear.—Practice varies somewhat in determining the outside or over-all diameter of the wormgear, as indicated by the following formulas. For usual rim shape, see Fig. 2.

1) For lead angles up to about 15 or 20 degrees, $D_0 = D + (3 \times 0.3183\ P)$

2) For lead angles over 20 degrees, $D_0 = D + (3 \times 0.3\ 183\ P \times \cos L_a)$

www.EngineeringEBooksPdf.com

3) For single and double thread, $D_0 = D_t + 0.4775P$

4) For triple and quadruple thread, $D_0 = D_t + 0.3183\,P$

Pressure Angles.—The pressure angle (one-half the included thread angle) ranges from 14½ to 30 degrees. While the practice varies somewhat, the following relationship between lead angle and pressure angle may be used as a general guide.

For lead angles up to about 10 or 12 degrees, pressure angle = 14½ degrees.

For lead angles from 10 or 12 to about 20 or 25 degrees, pressure angle = 20 degrees.

For lead angles from 25 to about 35 degrees, pressure angle= 25 degrees.

For lead angles over 35 degrees, pressure angle = 30 degrees.

In the British Standard specifications, the recommended thread form has a normal pressure angle of 20 degrees.

Designing Worm Gearing Relative to Center Distance and Ratio.—In designing worm gearing, three general cases or types of problems may be encountered in establishing the proportions of the worm and wormgear.

When Center Distance is Fixed and Ratio may be Varied: The ratio in this case is nominal and may be varied somewhat to meet other conditions. Assume that the required center distance is 6 inches, the desired ratio is about 7, and the pitch of the worm and wormgears is to be approximately 1 inch. Combinations of wormgears and worms such as the following might be used in this case:

$$\frac{28}{4}, \frac{35}{5}, \frac{42}{6}, \frac{56}{8}, \text{ etc.}$$

Suppose we select the $^{28}/_{4}$ combination for trial but change the number of worm-gear teeth from 28 to 29 to obtain a self-indexing or "hunting tooth" action. The ratio now equals $^{29}/_{4}$ or 7.25. Then, for trial purposes

$$\text{Pitch diameter } D \text{ of wormgear} = \frac{T \times P}{\pi} = \frac{29 \times 1}{3.1416} = 9.231 \text{ inches}$$

$$\text{Pitch diameter } d \text{ of wormgear} = 2C - D = 2 \times 6 - 9.231 = 2.769 \text{ inches}$$

Assume that experience, tests, or calculations show that a worm of smaller diameter will have the necessary bending and torsional strength and that a pitch of 1.0625 will be satisfactory. Then the pitch diameter of the worm will be decreased to 2.192 inches and the pitch diameter of the wormgear will be increased to 9.808 inches. A check of the lead-angle will show that it equals 31°41′ which is conducive to high efficiency.

When Ratio is Fixed and Center Distance may be Varied: Assume that the required ratio is 7¼ and that the center distance may be any value consistent with approved designing practice. This ratio may be obtained with a number of different worm and wormgear sizes. For example, in a series of commercial wormgears, the following combinations are employed for gearing having a ratio of 7¼ with center distances varying from 4 to 8.25 inches. The number of worm threads is 4 and the number of teeth on the wormgear is 29 in all cases.

When C = 4 inches, d = 1.654; D = 6.346; P = 0.6875; L_a = 27°54′

When C = 5 inches, d = 1.923; D = 8.077; P = 0.875; L_a = 30°5′

When C = 6 inches, d = 2.192; D = 9.808; P = 1.0625; L_a = 31°41′

When C = 7 inches, d = 2.461; D = 11.539; P = 1.25; L_a = 32°53′

When C = 8.25 inches, d = 2.942; D = 13.558; P = 1.4687; L_a = 32°27′

www.EngineeringEBooksPdf.com

The horsepower rating increases considerably as the proportions of the worm gearing increase; hence if the gears are intended primarily for power transmission, the general proportions must be selected with reference to the power-transmitting capacity, and, usually the smallest and most compact design that will give satisfactory performance should be selected. The power capacity of the transmission, however, does not depend solely upon the proportions of the worm and wormgear. For example, the quality and viscosity of the lubricant is an important factor. The load transmitting capacity of the lubricant may also be increased decidedly when excessive temperature rises are prevented by special means such as forced air cooling. (See *Water and Forced-Air Cooling*, page 3339)

When Both Ratio and Center Distance are Fixed: When both ratio and center distance are fixed, the problem usually is to obtain the best proportions of worm and wormgear conforming to these fixed values.

Example: The required ratio is 6 (6 to 1) and the center distance is fixed at 3.600 inches. Assume that experience or tests show that an axial pitch of 0.50 inch will meet strength requirements. If normal pitch P_n is given, change to axial pitch ($P = P_n \div \text{Cos } L_a$). With a ratio of 6, some of the combinations for trial are: $\frac{30}{5}, \frac{36}{6}, \frac{42}{7}$

Trial calculations will show that the $\frac{36}{6}$ combination gives the best proportions of worm and wheel for the center distance and pitch specified. Thus

$$D = \frac{TP}{\pi} = \frac{36 \times 0.5}{3.1416} = 5.729 \qquad d = 2C - D = 2 \times 3.6 - 5.729 = 1.471$$

The lead angle is about 33 degrees. The effect of lead angle on efficiency is dealt with in a following paragraph. The total obtained by adding the number of worm-gear teeth to the number of worm threads, equals 36 + 6 = 42 (a total of 40 is a desirable minimum). With the 42/7 combination of the same pitch, the worm would be too small (0.516 inch); and with the 30/5 combination it would be too large (2.426 inches). The present trend in gear designing practice is to use finer pitches than in the past. In the case of worm gearing, the pitch may, in certain instances, be changed somewhat either to permit cutting with available equipment or to improve the proportions of worm and wheel.

When Ratio, Pitch and Lead Angle are Fixed: Assume that $R = 10$, axial pitch $P = 0.16$ inch, $L_a = 30$ degrees and $C = 3$ inches, approximately.

The first step is to determine for the given ratio, pitch and lead angle, the number of worm threads t which will give a center distance nearest 3 inches.

The whole number nearest 10.04, or 10, is the required number of worm threads; hence number of teeth on wormgear equals $R \times 10 = 100$

$$d = (L \cot L_a) \div \pi = (10 \times 0.16 \times 1.732) \div \pi = 0.8821 \text{ inches}$$

$$D = (TP) \div \pi = (100 \times 0.16) \div \pi = 5.0929 \text{ inches}$$

$$C = (D + d) \div 2 = (5.0929 + 0.8821) \div 2 = 2.9875 \text{ inches}$$

Efficiency of Worm Gearing.— The efficiency at a given speed, depends upon the worm lead angle, the workmanship, the lubrication, and the general design of the transmission. When worm gearing consists of a hardened and ground worm running with an accurately hobbed wormgear properly lubricated, the efficiency depends chiefly upon the lead angle and coefficient of friction between the worm and worm-gear. In the lower range of lead angles, the efficiency increases considerably as the lead angle increases, as shown by Tables 5 and 6. This increase in efficiency remains practically constant for lead angles between 30 and 45 degrees. Several formulas for obtaining efficiency percentage follow:

www.EngineeringEBooksPdf.com

With worm driving:

$$E = 100 - \frac{R}{2}(\text{empirical rule}); E = \frac{100 \times \tan L_a}{\tan(L_a + \phi)}\ ;\ E = \frac{100 \times L}{L + f\pi d}$$

With wormgear driving

$$E = 100 - 2R(\text{empirical rule}); E = \frac{100 \times \tan(L_a - \phi)}{\tan L_a}$$

The efficiencies obtained by these formulas and other modifications of them differ somewhat and do not take into account bearing and oil-churning losses. The efficiency may be improved somewhat after the "running in" period.

[a] These values for different rubbing speeds are based upon the use of phosphor bronze wormgears with case-hardened ground and polished steel worms lubricated with mineral oil.

Self-locking or Irreversible Worm Gearing.—Neglecting friction in the bearings, worm gearing is irreversible when the efficiency is zero or negative, the lead angle being equal to or less than the angle ϕ of friction ($\tan \phi$ = coefficient of friction). When worm gearing is self-locking or irreversible, this means that the worm-gear cannot drive the worm. Since the angle of friction changes rapidly with the rubbing speed, and the static angle of friction may be reduced by external vibration, it is usually impracticable to design irreversible worm gearing with any security. If irreversibility is desired, it is recommended that some form of brake be employed.

Worm Gearing Operating Temperatures.—The load capacity of a worm gearing lubricant at operating temperature is an important factor in establishing the continuous power-transmitting capacity of the gearing. If the churning or turbulence of the oil generates excessive heat, the viscosity of the lubricant may be reduced below its load-supporting capacity. The temperature measured in the oil sump should not, as a rule, exceed 180 to 200 degrees F. or rise more than 120 to 140 degrees F. above a surrounding air temperature of 60 degrees F. In rear axle motor vehicle transmissions, the maximum operating temperature may be somewhat higher than the figures given and usually is limited to about 220 degrees F.

Thermal Rating.—In some cases, especially when the worm speed is comparatively high, the horsepower capacity of worm gearing should be based upon its thermal rating instead of the mechanical rating. To illustrate, worm gearing may have a thermal rating of, say, 60 H.P., and mechanical ratings which are considerably higher than 60 for the higher speed ranges. This means that the gearing is capable of transmitting more than 60 H.P. so far as wear and strength are concerned but not without overheating; hence, in this case a rating of 60 should be considered maximum. Of course, if the power to be transmitted is less than the thermal rating for a given ratio, then the thermal rating may be ignored.

Water and Forced-Air Cooling.—One method of increasing the thermal rating of a speed-reducing unit of the worm gearing type, is by installing a water-cooling coil through which water is circulated to prevent an excessive rise of the oil temperature. According to one manufacturer, the thermal rating may be increased as much as 35 per cent in this man-

www.EngineeringEBooksPdf.com

ner. Much larger increases have been obtained by means of a forced air cooling system incorporated in the design of the speed-reducing unit. A fan which is mounted on the worm shaft draws air through a double walled housing, thus maintaining a comparatively low oil bath temperature. A fan cooling system makes it possible to transmit a given amount of power through a worm-gearing unit that is much smaller than one not equipped with a fan.

Double-enveloping Worm Gearing.—Contact between the worm and wormgear of the conventional type of worm gearing is theoretically a line contact; however, due to deflection of the materials under load, the line is increased to a narrow band or contact zone. In attempting to produce a double-enveloping type of worm gearing (with the worm curved longitudinally to fit the curvature of the gear as shown Fig. 3), the problem primarily was that of generating the worm and worm-gear in such a manner as to obtain area contact between the engaging teeth. A practical method of obtaining such contact was developed by Samuel I. Cone at the Norfolk Navy Yard, and this is known as “Cone-Drive” worm gearing. The Cone generating method makes it possible to cut the worm and wormgear without any interference which would alter the required tooth form. The larger tooth bearing area and multiple tooth contact obtained with this type of worm gearing, increases the load-carrying or horsepower capacity so that as compared with a conventional worm drive a double-enveloping worm drive may be considerably smaller in size. Table 9, which is intended as a general guide, gives input horsepower ratings for Cone-Drive worm gearing for various center distances of from 2 to 12 inches. These ratings are based on AGMA specifications 341, 441, and 641. They allow for starting and momentary peak overloads of up to 300 per cent of the values shown in Table 5 using a service factor of 1. Factors for various types of service are given in Table 8. To obtain the mechanical horsepower rating required, multiply the appropriate rating given in Table 9 by the service factor taken from Table 8.

[a] Horsepower ratings are for Class 1 service, using spalsh lubrication, except for that shown in italics, for which force feed lubrication is required. Other ratios and center distances are available. *Source*: Ex-Cell-O Corp., Cone Drive Operations

Thermal Horsepower Rating: When the operation is to be continuous, consideration must be given to the possibility of overheating. For this possibility, the thermal horsepower rating given in Ex-Cell-O Corporation, Cone Drive Operations catalog must be checked. The thermal rating defines the maximum horsepower which can be transmitted continuously (30 minutes or longer). This is based on an oil sump temperature rise of 100 deg. F above the ambient temperature. This rise must not exceed 200 deg. F. If the thermal rating is lower than the mechanical rating, the unit must be selected on the basis of the thermal rating.

Type of Drive Connection: If either input or output shaft is connected to driver or driven mechanism by other than a direct shaft coupling, the overhead load requirement (chain pull) must be calculated by dividing the torque demand by the pitch radius of the sprocket, sheave, spur gear, or helical gear used. The result is multiplied by the overhung load factor which is: for a chain sprocket, 1.00; for spur or helical gearing, 1.25; for a V-belt sheave, 1.50; and for a flat belt sheave, 2.50. As modified by the applicable overhung load factor, this load may not exceed the overhung load rating given in the company catalog.

Locking Considerations: It is a common misconception that all worm gears are self-locking or non-overhauling. Actually, wormgear ratios up 15 to 1 will overhaul quite freely. Ratios from 20:1 to 40:1 can generally be considered as overhauling with difficulty, particularly from rest. Ratios above 40:1 may or may not overhaul depending on the loading, lubrication, and amount of vibration present. Therefore it is not acceptable to rely on a wormgear to prevent movement in a system. Whenever a load must be stopped or held in

www.EngineeringEBooksPdf.com

place, a positive mechanical device must be incorporated into the system to prevent rotation of the gearset.

Backdriving or Overhauling: Applications such as wheel drives that require a brake on the motor or input shaft to decelerate a high inertial load require special attention to brake selection. Wherever possible, these applications should utilize freely overhauling ratios (15:1 or less). If higher ratios are used with a brake, the gearset can, under certain conditions, lockup during deceleration and impose severe shock loading on the reducer and driven equipment.

Stairstepping: Self-locking ratios (generally 40:1 and higher) are susceptible to the phenomenon of "stair stepping" when back driving or overhauling. This erratic rotation of the gear set occasionally occurs when the gear set is back driven at worm speeds less than the theoretical lockup speed of the gear set and can be amplified by the rest of the drive train creating a very undesirable operating condition. "Stair stepping" can occur on drives where there is a high inertial load at the output shaft.

Backlash: Defined as the amount of movement at the pitch line of the gear with the worm locked and the gear set on exact center distance, backlash normally ranges from 0.003 to 0.008 inch for a 2-inch center distance set up to 0.012 to 0.020 inch for a 12-inch center distance set. When the gear set is assembled into a machine or reducer, the assembled backlash may fall outside these limits depending upon worm and gear bearing looseness and the actual center distance used.

Lubrication: Lubricating oils for use in double-enveloping worm drive units should be well refined petroleum oils of high quality. They should not be corrosive to gears or bearings and they must be neutral in reaction and free from grit or abrasives. They should have good defoaming properties and good resistance to oxidation. For worm gears, add up to 3 to 10 per cent of acid less tallow or similar animal fat.

The oil bath temperature should not exceed 200 degrees F. Where worm speed exceeds 3600 revolutions per minute, or 2000 feet per minute rubbing speed, a force feed lubrication may be required. Auxiliary cooling by forced air, water coils in sump, or an oil heat exchanger may be provided in a unit where mechanical horsepower rating is in excess of the thermal rating, if full advantage of mechanical capacity is to be realized. The rubbing speed (V), in feet per minute, may be calculated from the formula:

$$V = 0.262 \times \text{worm throat diameter in inches} \times \text{worm RPM} \div \cos \text{lead angle}$$

Worm Thread Cutting.—Worm threads are cut either by using some form of thread-cutting lathe and a single-point tool, by using a thread milling machine and a disk type of cutter, or by using a gear-hobbing machine. Single-thread worms usually have an included angle of 29 degrees. Many worm gears used at the present time, especially for power transmission, have thread angles larger than 29 degrees because multiple-thread worms are used to obtain higher efficiency, and larger thread angles are necessary in order to avoid excessive under-cutting of the worm-wheel teeth. According to the recommended practice of the American Gear Manufacturers' Association, worms having triple and quadruple threads should have a thread angle of 40 degrees, and some manufacturers of worm gearing, especially when the helix or lead angle of the thread is quite large, use a thread angle of 60 degrees.

If the helix or lead angle of the worm thread exceeds 15 or 20 degrees, it is common practice to reduce the depth of the thread by using the normal instead of the axial pitch of the worm in the formulas. Thus, if P_n equals normal pitch, the total depth equals $P_n \times 0.6866$ instead of $P_n = 0.6866$. This normal pitch P_n, equals $P_n \times$ cosine of the helix angle. According to the recommended practice of the American Gear Manufacturers' Association, the whole depth for single- and double-thread worms equals $P_n \times 0.686$, and for triple and quadruple-thread worms equals $P_n \times 0.623$.

www.EngineeringEBooksPdf.com

Hobs for Gearing

Wormgear Hobs.—An ideal hob would have exactly the same pitch diameter and lead angle as the worm; repeated sharpening, however, would reduce the hob size because of the form-relieved teeth. Hence, the general practice is to make hobs (especially the radial or in-feed type) "over-size" to provide a grinding allowance and increase the hob life. An over-size hob has a larger pitch diameter and smaller lead angle than the worm, but repeated sharpenings gradually reduce these differences. To compensate for the smaller lead angle of an over-size hob, the hob axis may be set 90-degrees relative to the wormgear axis plus the difference between the lead angle of the worm at the pitch line, and the lead angle of the over-size hob at its pitch line. This angular adjustment is in the direction required to increase the inclination of the wormgear teeth so that the axis of the assembled worm will be 90 degrees from the wormgear axis. ("Lead angle" is measured from a plane perpendicular to worm or hob axis.)

Hob Diameter Formulas: If

D = pitch diameter of worm;
D_h = pitch diameter of hob;
A = addendum of worm and wormgear;
C = clearance between worm and worm-gear;
S = increase in hob diameter or "over-size" allowance for sharpening.

Outside diameter O of hob= $D + 2A + 2C + S$

Root diameter of hob = $D - 2A$

Pitch diameter D_h of hob = O–$(2A + 2C)$

Sharpening Allowance: Hobs for ordinary commercial work are given the following sharpening allowance, according to the recommended practice of the AGMA: In this formula, h = helix angle of hob at outside diameter measured from axis; H= helix angle of hob at pitch diameter measured from axis.

$$\text{Sharpening allowance} = 0.075 \times \text{normal pitch} \times \left[\frac{16 - (h - H)}{16}\right] + 0.010$$

Number of Flutes or Gashes in Hobs: For finding the approximate number of flutes in a hob, the following rule may be used: Multiply the diameter of the hob by 3, and divide this product by twice the linear pitch. This rule gives suitable results for hobs for general purposes. Certain modifications, however, are necessary as explained in the following paragraph.

It is important that the number of flutes or gashes in hobs bear a certain relation to the number of threads in the hob and the number of teeth in the wormgear to be hobbed. In the first place, avoid having a common factor between the number of threads in the hob and the number of flutes; that is, if the worm is double-threaded, the number of gashes should be, say, 7 or 9, rather than 8. If it is triple threaded, the number of gashes should be 7 or 11, rather than 6 or 9. The second requirement is to avoid having a common factor between the number of threads in the hob and the number of teeth in the wormgear. For example, if the number of teeth in the wheel is 28, it would be best to have the hob triple-threaded, as 3 is not a factor of 28. Again, if there were to be 36 threads in the wormgear, it would be preferable to have 5 threads in the hob.

The cutter used in gashing hobs should be from $\frac{1}{8}$ to $\frac{1}{4}$ inch thick at the periphery, according to the pitch of the thread of the hob. The width of the gash at the periphery of the hob should be about 0.4 times the pitch of the flutes. The cutter should be sunk into the hob blank so that it reaches from $\frac{3}{16}$ to $\frac{1}{4}$ inch below the root of the thread.

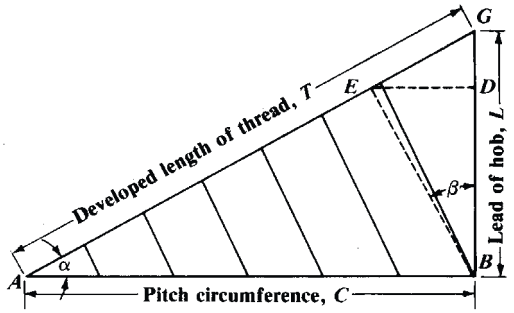
Helical Fluted Hobs.—Hobs are generally fluted parallel with the axis, but it is obvious that the cutting action will be better if they are fluted on a helix at right angles with the

www.EngineeringEBooksPdf.com

thread helix. The difficulty of relieving the teeth with the ordinary backing-off attachment is the cause for using a flute parallel with the axis. Flutes cut at right angles to the direction of the thread can, however, also be relieved, if the angle of the flutes is slightly modified. In order to relieve hobs with a regular relieving attachment, it is necessary that the number of teeth in one revolution along the thread helix be such that the relieving attachment can be geared to suit it. The following method makes it possible to select an angle of flute that will make the flute come approximately at right angles to the thread, and at the same time the angle is so selected that the relieving attachment can be properly geared for relieving the hob.

Let

C = pitch circumference
T = developed length of thread in one turn;
N = number of teeth in one turn along thread helix;
F = number of flutes;
α = angle of thread helix.



Then $C \div F$= length of each small division on pitch circumference;
$(C \div F) \times \cos \alpha$ = length of division on developed thread;
$C \div \cos \alpha = T$
Hence

$$\frac{T}{(C \div F)\cos\alpha} = N = \frac{F}{\cos\alpha^2}$$

Now, if

$$\alpha = 30 \text{ degrees}, N = 1\tfrac{1}{3}F;$$
$$\alpha = 45 \text{ degrees}, N = 2F;$$
$$\alpha = 60 \text{ degrees}, N = 4F.$$

In most cases, however, such simple relations are not obtained. Suppose for example that $F = 7$, and $\alpha = 35$ degrees. Then $N = 10.432$, and no gears could be selected that would relieve this hob. By a very slight change in the helix angle of the flute, however, we can change N to 10 or $10\frac{1}{2}$; in either case we can find suitable gears for the relieving attachment.

The rule for finding the modified helical lead of the flute is: Multiply the lead of the hob by F, and divide the product by the difference between the desired values of N and F.

Hence, the lead of flute required to make N = 10 is:

Lead of hob $\times (7 \div 3)$.

To make $N = 10\frac{1}{2}$, we have:

Lead of flute = lead of hob $\times (7 \div 3.5)$.

From this the angle of the flute can easily be found.

www.EngineeringEBooksPdf.com

That the rule given is correct will be understood from the following consideration. Change the angle of the flute helix β so that *AG* contains the required number of parts *N* desired. Then *EG* contains *N*–*F* parts. But cotβ = *BD*÷ *ED* and by the law of similar triangles,

$$BD = \frac{F}{N} \times BG, \text{ and } ED = \frac{N-F}{N} C$$

The lead of the helix of the flute, however, is $C \times \cot \beta$.

Hence, the required lead of the helix of the flute:

$$C \times \cot\beta = \frac{F}{N-F} L$$

This formula makes it possible always to flute hobs so that they can be conveniently relieved, and at the same time have the flutes at approximately right angles to the thread.

Gear Shaving.—The purpose of gear shaving is to correct errors in indexing, helix angle, tooth profile, and eccentricity by removing small amounts of material from the working surfaces of gear teeth. Special shaving cutters are used and have tooth flanks with sharp-edged grooves that traverse the tooth surfaces of the gear to be corrected as the hardened, driven cutter and the softer (30-35 Rockwell C) free-running gear are rotated in mesh on crossed axes in a special machine. The crossed angle is usually between 10 and 15 degrees, or half the difference between the helix angles of cutter and gear. In conventional shaving, the gear is held between live centers on the machine table, which is moved parallel to the gear axis, and is fed into contact with the cutter at each successive stroke of the table. Cutter speeds of up to 450 surface feet/min are commonly used.

The crossed axes cause the sharp-edged grooves on the cutter to traverse the tooth surfaces on the gear as cutter and gear rotate, resulting in a shearing action that cuts fine slivers from the gear tooth surfaces. At the same time, contact between the meshing sets of teeth has a burnishing action on the gear teeth, improving the surface finish. Shaving can remove 60-80 per cent of errors in a gear, and can produce accuracies of 0.0002 in. on the involute profile, 0.0003 in. on tooth-to-tooth spacing, and 0.0002 in. on lead or parallelism.

Gear-shaving machines have built-in mechanisms that can be used to rock the table as it traverses, producing crowned gear teeth that are slightly thicker at the center than at the ends. In the faster diagonal shaving method, the traversing movement of the table is at an angle to the gear axis, so that the cutter grooves move more rapidly across the gear, increasing the shaving action.

Speeds and Feeds for Gear Cutting

Speeds and Feeds for Gear Cutting.—The variations in speed and feed, owing to limiting conditions, are probably greater for gear cutting than for most other machining operations. The important factors governing the speed arid feed, aside from the design and condition of the machine, are the pitch of the gear to be cut, the hardness of the metal, the kind of steel used for making the cutter, the form and condition of the cutter, the rigidity of the gear blank when mounted for cutting, the accuracy and finish required for the gear, and the cutting lubricant used in the case of steel gears. The following speeds are given by Gould & Eberhardt as a fair average for cutting medium grades of cast iron and steel, when using carbon and high-speed steel cutters;

Material	Carbon Steel Cutters			High-speed Steel Cutters		
	Min.	Average	Max.	Min.	Average	Max.
Cast iron, feet per minute	35	45	60	60	70	80
Steel, feet per minute	25	30	40	45	50	55

www.EngineeringEBooksPdf.com

While these figures are based upon gear-cutting practice, they are merely intended to serve as a guide until the most economical speed for a given case can be determined by actual tests. More specific data on speeds and feeds are given in the table *Speeds and Feeds for Gear Cutting*. This table applies to machines of the rotary cutter type and covers diametral pitches varying from 1 to 20. The feeds and speed listed are for cast iron and steel gears of medium grade, with suitable variation for carbon or high-speed steel cutters. The first column gives the maximum capacity of the machine, in diametral pitch; it will be noted that the values vary somewhat for a gear of given pitch, for machines of different capacity. For example when a cast-iron gear of 6 diametral pitch is cut on a machine having a capacity 3 diametral pitch, the feed per minute is given as 4.5 inches; but when the sane pitch is cut on a larger machine of 2 diametral pitch capacity, the feed can be increased to 11.5 inches per minute, high-speed steel cutters being used in each case.

[a] Compiled by Gould & Eberhardt.

Feeds for Hobbing.— The feeds for hobbing usually vary from about 0.020 to 0.200 inch per revolution of the gear. Gould & Eberhardt recommend th following feeds for hobbing spur gears. The figures give the movement of the hob per revolution of the gear.

Material	Feed Inches	Material	Feed Inches	Material	Feed Inches
Tool Steel	0.010	Soft Steel	0.040	Roughing Soft Steel	0.080
Tough Steel	0.020	Average Cast Iron	0.050	Roughing Average Cast Iron	0.100
Average Steel	0.030	Soft Cast Iron	0.060	Roughing Soft Cast Iron	0.150

When hobbing helical gears, the feed depends somewhat upon the angle of the teeth. For angles varying trom 0 to 36 degrees the feed should be about the same a for spur gears; for angles from 36 to 48 degrees, the feed should equal $\frac{4}{5}$ of that for spur gears; from 48 to 60 degrees, $\frac{2}{3}$ of the spur gear feed; from 60 to 70 degrees $\frac{1}{2}$ of the spur gear feed; for angles above 70 degrees, $\frac{1}{8}$ of the spur gear feed. The feed is diminished in the case of helical gears, because when the hob is set to conform to the helix angle, the feed of the cutter, per revolution, is increased by the turning movement of the gear blank necessary for generating the helical teeth.

Feeds for Given Pitch and Material.— The table *Feeds for Gear Cutting* contain practical data on the feeds to use for different materials and pitches. The data in the table apply to high-speed steel cutters and are intended as a general guide only. The feeds listed vary according to diametral pitch, kind of material an nature of cut. The shearing-tooth cutter for roughing, referred to in the tables, an ordinary gear cutter having faces of alternate teeth ground at an angle of 11 degrees, so that the teeth have rake and cut similar to a side turning tool. Cast iron gears up to $2\frac{1}{2}$ diametral pitch can usually be finished in one cut with a rotar formed cutter. Cast-iron gears coarser than 2 diametral pitch should, as a rule have the teeth roughened or "blocked out" prior to finishing.

Compiled by the Cincinnati Gear Cutting Machine Co. The gears are assumed to be of substantial design, and the belts on the machine to be in good condition. For steel gears, a lard oil lubricant is used. For teeth coarser than 1 3/4 diametral pitch, feeds are not given for finishing in one cut, because satisfactory results cannot be obtained with a single cut on the No. 7 machine.

Other Gear Topics

Hunting Tooth Gear Ratios.— When the numbers of teeth in a pair of meshing gears are such that they do not have a common divisor, the ratio of the tooth numbers is said to be a "hunting tooth" or non-factorizing ratio. Each gear in such a pair must make as many revolutions as its mating gear has teeth for a particular tooth on that gear to "hunt" or mesh once with every tooth on the mating gear. For example, with a pair having 73/24 teeth, a particular tooth on the 73-tooth gear will mesh once with every tooth on the 24-tooth gear when the 73-tooth gear has made 24 revolutions. In the same way, a particular tooth on the

www.EngineeringEBooksPdf.com

24-tooth gear will mesh once with every tooth on the 73-tooth gear in 73 revolutions of the 24-tooth gear.

When several pairs of gears operating at the same center distance are required to have hunting ratios, this can be accomplished by having the sum of the teeth in each pair equal to a prime number. Thus $^{77}/_{20}$, $^{76}/_{21}$, $^{75}/_{19}$, etc., are all hunting ratios and each pair sum is 97, a prime number.

Origin of Hunting Tooth Use: Whenever the number of teeth on a gear is equal to some whole number multiplied by the number of teeth on the mating pinion, then any tooth on the gear meshes with the same tooth on the pinion during each revolution of the gear. For example, with a $^{72}/_{24}$ pair, one tooth on the 24-tooth pinion will always mesh with the same three teeth on the gear. Changing the ratio to $^{72}/_{24}$ produces the hunting tooth condition described previously.

The practice of using "hunting" ratios was common when gears of high accuracy were not available as was the case with the cast iron gears used by millwrights. The theory was that, with a hunting tooth, gear wear would be evenly distributed among all the teeth and they would eventually wear into some indefinite but comparatively true (conjugate) tooth form which operated more quietly and lasted longer than gears of even ratios.

When to Use Hunting Ratios: The following conditions favor hunting tooth ratios:

1. Both gears are hardened or hardened and ground. In this case the gears are too hard to wear in much, but use of the hunting tooth prevents high dynamic tooth loads from being confined to a single pair of teeth thus increasing gear life.

2. The gear pair is subject to high cyclic loads such as in a crankshaft. In this case a hunting ratio distributes the high loads to all the teeth evenly and prevents early breakage of certain teeth resulting when integral ratios are used.

When Not to Use Hunting Ratios: Hunting ratios should not be used in the following situations:

1. For multiple-start worm drives that require long life. If a hunting ratio is used, the hard material of the worm would continually shave particles from the softer worm gear throughout the life of the drive whereas an integral ratio would bed itself in after a short time, and further wear would be small.

2. When gears are repeatedly assembled and disassembled as in the case of change gears; it is of no importance whether they have a common factor or are hunting ratios.

3. If gears are finished by lapping as in the case of automotive bevel gears, even ratios may be used provided the gears are assembled meshed as they were in the lapping process. If this is not practical, then a hunting ratio is more satisfactory.

Maag Gearing.—In the design of the Maag system of gearing, a 15-degree pressure angle is maintained for large gears, but for relatively small gears the angles and also the blank diameters or positions of the teeth relative to the pitch circles, are varied with the idea of obtaining the most satisfactory operation for gearing of a given ratio. This is a departure from standardization and the use of gears which are interchangeable at standard center distances. Those advocating this system, however, believe that what is lost in this respect is more than gained by so forming the teeth of a gear and pinion of given ratio as to obtain more rolling and less sliding action combined with stronger teeth without under-cutting, even when the gears are very small. When necessary or desirable to use gears having possibly not more than five or six teeth, a practical tooth form may be obtained by changing the pressure angle and the relation of the tooth to its pitch circle, to suit the conditions. It has long been the practice to obtain an improvement of tooth shape by the enlargement of small spur and bevel pinions but with the Maag system, the plan is to so modify the relations between addenda, dedenda, and pressure angle as to secure what is considered the best tooth form for each particular ratio.

www.EngineeringEBooksPdf.com

MACHINE ELEMENTS

Bearings

Percentages of Radial and Thrust Loads.—There are three types of bearing that are combined load carriers: First, the annular ball bearing, which is primarily designed for radial loads and has no angle of contact incorporated in its design, therefore having minimum thrust capacity (approximately 20 per cent of its radial capacity). Second, the one-direction angular contact bearing, which has a thrust capacity depending upon race design and the angle incorporated, which is generally made so that the thrust capacity is 100 per cent of the radial capacity. (This bearing, however, when used for combined loads, can only be used in pairs, and must have a threaded or shim adjustment incorporated in the mounting design to allow for initial adjustment.) Third, the double angular type bearing which is really two of the previously mentioned bearings built as a self-contained unit. The functioning of this bearing is not dependent on any exterior adjustment, and the angle of contact is generally such that it will sustain approximately 150 per cent of its radial capacity as thrust.

Roller Bearing.—The load on roller bearings is supported by cylindrical or conical rollers interposed between two races, one race being mounted on the shaft and one other in the bearing proper. There are three principal designs of roller bearings. One is for straight radial loads, the lines of contact of the rollers with the races being parallel with the shaft axis, as shown by the left-hand diagram; another design is for combined radial and thrust loads (See Fig. 1b.). With this design, the rollers are tapering so that the lines of contact of the rollers with the races, and the axis of the rollers, will intersect, if extended, at the same point on the shaft axis. A third design is intended for thrust or axial loads exclusively. Bearings for radial loads may have solid rollers, or the hollow helically-wound type such as is used in the Hyatt bearing. Although anti-friction bearings have replaced a great many plain or sliding bearings, the trend is toward a much wider application, and evidently will include eventually the heaviest classes of service since modern anti-friction bearings not only greatly reduce friction losses, but lower maintenance and repair costs.

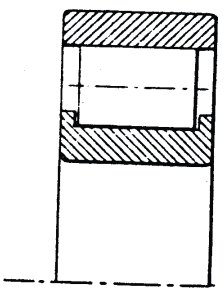

Fig. 1a. Bearing for Radial Load

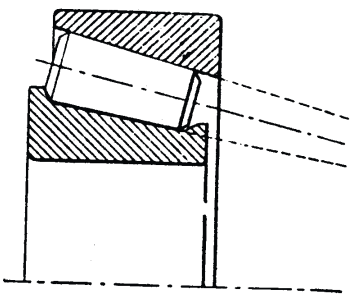

Fig. 1b. Bearing for Radial and Thrust Loads

Ball Bearing Lubrication.—To obtain the full measure of efficiency and service from ball and roller bearing equipment, the kind and quality of the lubricant, as well as the system of applying it, must be adapted to the design of the bearing, the design of the machine, and the operating conditions.

Operating Temperatures: Under ordinary conditions the temperature of a bearing while running will be from 10 to 60 degrees F. above that of the room. If it exceeds 125 degrees F., ordinary greases will frequently prove unsatisfactory. They will tend to soften and flow continuously into the path of the rolling elements, causing a rise in the normal operating temperature due to the increased frictional resistance introduced. This may eventually result in the separation of the oil and soap base, with a complete loss of lubricating qualities. In some cases, greases developed for use at high temperatures may be employed. Care

www.EngineeringEBooksPdf.com

should be taken, however, to see that they meet all the requirements for adequate lubrication.

Mineral oil of proper physical and chemical properties is an ideal lubricant for ball and roller bearings when the housing is designed to control the quantity entering the bearing and to prevent leakage and protect the bearing from the entrance of foreign matter. A ball or roller bearing should not be subjected to temperature in excess of 300 degrees F., because of the danger of drawing the temper of the hardened steel races and balls.

Quantity of Lubricant Required: In no case does a ball or roller bearing require a large quantity of lubricant. On the contrary, a few drops of oil, or a corresponding amount of grease, properly distributed over the running surfaces of the bearing, will provide satisfactory lubrication for a considerable period of time. A large volume of lubricant within a bearing will usually result in high operating temperatures, due to the working or churning of the lubricant by the rolling elements and retainer. This may seriously impair the useful life of the lubricant through oxidation or sludging of the oil or actual disintegration of greases.

Use of Grease: If grease is used, the housing should not be kept more than one-fourth to one-half full of the lubricant. Unlike oil, there is no way of controlling with any degree of exactness the quantity of grease in a housing, and greater care must therefore be taken to avoid overloading. A bearing that runs at too high a temperature will often return to normal temperature if some of the lubricating grease is removed.

Grease is being used successfully for the lubrication of ball bearings at high speeds, but great care is necessary, both from the standpoint of housing design and selection of the lubricant, in order to obtain satisfactory results. Any system employed must be designed to feed only a limited amount of grease to the bearing. For the average application at operating speeds up to 3600 revolutions per minute, a grease of soft consistency, such as a No. 2 grease, will usually be found satisfactory, provided it is suitable in other respects. Hard greases, such as No. 3, may be used if the grease is to serve as a packing medium around the shaft to prevent the entrance of dirt, water, or other corrosive substances.

Sealed Bearings: : Bearings for certain classes of service must operate over long periods without relubrication, as, for example, a motor installation on an airplane beacon; hence the efforts of ball-bearing manufacturers to produce bearings so completely sealed as to enable them to retain their original charge of grease for many months. In appreciation of this requirement, the petroleum industry has developed lubricants that will maintain lubrication for a long period without change in structure, homogeneity, lubricating properties, or leakage.

Oilless Bearings.—Oilless or self-lubricating bearings are especially adapted for applications in places where oiling is undesirable, or where the bearings are difficult of access, or likely to be neglected. They are of particular value in such plants as canneries, textile mills, etc., where the product is liable to harm from dripping oil, and oilless bearings are applied in many other classes of service. A number of different types of oilless bearings have been developed, each of which doubtless has its advantages when applied under suitable conditions. One type consists of wood impregnated with wax, oil or paraffin; another is made of bronze and has graphite inserts; another type is formed of graphite impregnated with some bearing metal such as a white alloy or bronze; and still another consists of hard maple reinforced by babbitt metal, the wood shell of which is impregnated with lubricants and thus serves as an oil reservoir.

Another group of oilless bearings are porous bearings. These are usually of plain or leaded bronze, sometimes of iron, stainless steel and more rarely, aluminum and are made from powdered metal that has been pressed into the desired shape and then sintered, producing a sponge-like structure capable of absorbing fairly large quantities of oil, usually about 25 per cent of the volume of the bearing material. These bearings are used where lubrication supply is difficult, inadequate, or infrequent. This type of bearing should be

www.EngineeringEBooksPdf.com

flooded from time to time to resaturate the metal. In bearings of these materials the allowable rubbing speed may range up to 2000 fpm with very light loads. The usual operating speed range would be, however, from 75 to 1500 fpm. For porous bearings impregnated with oil the maximum operating temperature is about 150 degrees F. Tests have shown that applied loads should be steady and unidirectional and clearances between shaft and bearing should be between 0.0007 and 0.0012 inches. These materials are generally employed as bushings rather than in split shell bearings.

Thermoil-Granodine.—A coating material developed to prevent wear and rust of machine parts. Applied by immersing the machine parts, after thorough cleaning, in a boiling solution of the coating material. The solution transforms the surface into a layer of iron and manganese phosphates, which becomes an integral part of the metal beneath. Suitable for treating automobile engine parts, such as pistons, valves, and camshafts; gears; and any machine parts having bearing surfaces.

Knife-Edge Bearings.—So-called "knife-edge" bearings are used on weighing and testing machines. When the knife-edge bearing as well as the seat are made of the proper material, the knife-edge will sustain loads up to 10,000 pounds per inch of length; but ordinarily about 5000 pounds is the usual limit of pressure. The knife-edge, as well as the seat bearing upon it, should be made from tool steel having a carbon content of from 0.9 to 1 per cent. The knife-edge should be properly supported underneath its whole length in order to prevent deflection. The angle of the knife-edge should be 90 degrees for heavy loads. It should have a very slight flat at the extreme point, so small, however, that it is barely visible, because a pronounced flat or radius at the edge decreases the accuracy of the device. This flat may be obtained by rubbing with an oilstone. The seat against which the knife-edge bears, if made of an angular form, should be provided with a small round at the vertex of the angle.

Kerosene Lubrication.—Kerosene has proved effective as a lubricant for the plain bearings of grinding wheel spindles. The following information is based upon the experience of the Norton Co. This type of lubrication is recommended only for plain bearings to which an ample flow of lubricant is delivered. It is not recommended for drip-lubricated bearings. The spindle journals of machines intended for kerosene lubrication are finished by methods that give them a highly reflective mirror-like surface. The surfaces thus finished are accurate in size and straightness to 0.0001 inch, and show readings from 1 to 2 microinches on the profilometer.

While kerosene has been used for many years as a spindle lubricant in the high-speed internal spindles supplied with Norton tool and cutter grinders, a high-quality oil with a Saybolt viscosity rating of from 60 to 185 at 100 degrees F. has previously been employed for the spindles of external grinders which operate at speeds ranging from about 800 to 1800 R.P.M., depending on the grinding wheel diameter. From 0.001 to 0.002 inch clearance for oil was provided in the bearings, and a bearing temperature of about 140 degrees F. was considered normal. With kerosene lubrication, these clearances can be safely reduced to approximately one-fifth of that formerly provided, and the temperature of the bearing will not rise much, if any, above 100 degrees F. The kerosene temperature does not rise above 100 degrees F. and with kerosene lubrication the fluctuations in temperature are very slight. Consequently, the repetitive expansion and contraction changes of the grinding wheel unit elements are greatly reduced.

Standard Metal Balls

American National Standard ANSI/AFBMA Std 10-1989 provides information for the user of metal balls permitting them to be described readily and accurately. It also covers certain measurable characteristics affecting ball quality.

On the following pages, tables taken from this Standard cover standard balls for bearings and other purposes by type of material, grade, and size range; preferred ball sizes; ball hardness corrections for curvature; various tolerances, marking increments, and maximum surface roughnesses by grades; total hardness ranges for various materials; and minimum case depths for carbon steel balls. The numbers of balls per pound and per kilogram for ferrous and nonferrous metals are also shown.

Definitions and Symbols.—The following definitions and symbols apply to American National Standard metal balls.

Nominal Ball Diameter, D_w*:* The diameter value that is used for the general identification of a ball size, e.g., ¼ inch, 6 mm, etc.

Single Diameter of a Ball, D_{ws}*:* The distance between two parallel planes tangent to the surface of a ball.

Mean Diameter of a Ball, D_{wm}*:* The arithmetical mean of the largest and smallest single diameters of a ball.

Ball Diameter Variation, V_{Dws}*:* The difference between the largest and smallest single diameters of one ball.

Deviation from Spherical Form, ΔR_w*:* The greatest radial distance in any radial plane between a sphere circumscribed around the ball surface and any point on the ball surface.

Lot: A definite quantity of balls manufactured under conditions that are presumed uniform, considered and identified as an entirety.

Lot Mean Diameter, D_{wmL}*:* The arithmetical mean of the mean diameter of the largest ball and that of the smallest ball in the lot.

Lot Diameter Variation, V_{DwL}*:* The difference between the mean diameter of the largest ball and that of the smallest ball in the lot.

Nominal Ball Diameter Tolerance: The maximum allowable deviation of any ball lot mean diameter from the Nominal Ball Diameter.

Container Marking Increment: The Standard unit steps in millionths of an inch or in micrometers used to express the Specific Diameter.

Specific Diameter: The amount by which the lot mean diameter (D_{wmL}) differs from the nominal diameter (D_w), accurate to the container marking increment for that grade; the specific diameter should be marked on the unit container.

Ball Gage Deviation, ΔS*:* The difference between the lot mean diameter and the sum of the nominal mean diameter and the ball gage.

Surface Roughness, R_a*:* Surface roughness consists of all those irregularities that form surface relief and are conventionally defined within the area where deviations of form and waviness are eliminated. (See Handbook Surface Texture Section.)

Ordering Specifications.—Unless otherwise agreed between producer and user, orders for metal balls should provide the following information: quantity, material, nominal ball diameter, grade, and ball gage. A *ball grade* embodies a specific combination of dimensional form, and surface roughness tolerances. A *ball gage(s)* is the prescribed small amount, expressed with the proper algebraic sign, by which the lot mean diameter (arithmetic mean of the mean diameters of the largest and smallest balls in the lot) should differ from the nominal diameter, this amount being one of an established series of amounts as shown in the table below. The 0 ball gage is commonly referred to as “OK”.

500	13	13	[a]	25	50	[a]
1000	25	25	[a]	50	125	[a]

[a] Not applicable.

Allowable ball gage (see text) deviation is for Grade 3: + 0.000030, – 0.000030 inch (+0.75, – 0.75 μm); for Grades 5, 10, and 16: + 0.000050, – 0.000040 inch (+ 1.25, – 1 μm); and for Grade 24: + 0.000100, – 0.000100 inch (+ 2.5, – 2.5 μm). Other grades not given.

Examples: A typical order, in inch units, might read as follows: 80,000 pieces, chrome alloy steel, ¼-inch Nominal Diameter, Grade 16, and Ball Gage to be –0.0002 inch.

www.EngineeringEBooksPdf.com

A typical order, in metric units, might read as follows: 80,000 pieces, chrome alloy steel, 6 mm Nominal Diameter, Grade 16, and Ball Gage to be –4 µm.

Package Marking: The ball manufacturer or supplier will identify packages containing each lot with information provided on the orders, as given above. In addition, the specific diameter of the contents shall be stated. Container marking increments are listed in Table 1.

Examples: Balls supplied to the order of the first of the previous examples would, if perfect size, be D_{wmL} = 0.249800 inch. In Grade 16 these balls would be acceptable with D_{wmL} from 0.249760 to 0.249850 inch. If they actually measured 0.249823 (which would be rounded off to 0.249820), each package would be marked: 5,000 Balls, Chrome Alloy Steel, ¼″ Nominal Diameter, Grade 16, –0.0002 inch Ball Gage, and –0.000180 inch Specific Diameter.

Balls supplied to the order of the second of the two previous examples would, if perfect size, be D_{wmL} = 5.99600 mm. In Grade 16 these balls would be acceptable with a D_{wmL} from 5.99500 to 5.99725 mm. If they actually measured 5.99627 mm (which would be rounded off to 5.99625 mm), each package would be marked: 5,000 Balls, Chrome Alloy Steel, 6 mm Nominal Diameter, Grade 16, –4 µm Ball Gage, and –3.75 µm Specific Diameter.

For complete details as to material requirements, quality specifications, quality assurance provisions, and methods of hardness testing, reference should be made to the Standard.

Table 2. AFBMA Standard Balls — Typical Nominal Size Ranges by Material and Grade

Tungsten carbide	JIC Carbide Classification	…	84-91.5 "A"

[a] Rockwell Hardness Tests shall be conducted on parallel flats in accordance with ASTM Standard E18 unless otherwise specified.

[b] Hardness readings taken on spherical surfaces are subject to the corrections shown in Table 5. Hardness readings for carbon steel balls smaller than 5 mm (¼ inch) shall be taken by the microhardness method (detailed in ANSI/AFBMA Std 10-1989) or as agreed between manufacturer and purchaser.

[c] Hardness of balls in any one lot shall be within 3 points on Rockwell C scale.

[d] When microhardness method (see ANSI/AFBMA Std 10-1989 is used, the Rockwell hardness values given are converted to DPH in accordance with ASTM Standard E 140, "Standard Hardness Conversion Tables for Metals."

[e] Choice of carbon steels shown to be at ball manufacturer's option.

[f] Hardness of balls in any one lot shall be within 4 points on Rockwell C scale.

[g] Annealed hardness of 75-90 "B" is available when specified.

Cement

The cements used in concrete construction are classified as:

1) Portland cements,
2) Natural cements,
3) Pozzuolanic, pozzuolan, or slag cements.

These different classes are all hydraulic cements as they will set or harden under water. When the powdered cement is mixed with water to a plastic condition, the cement sets or solidifies as the result of chemical action. After the preliminary hardening or initial set, the cement slowly increases in strength, the increase extending over months or years.

In the United States, portland cements are manufactured to comply with ASTM C 150, which defines five main types of portland cement. Type I, which is made in the greatest quantity, is intended for general use when the special properties of the other types are not required. The special properties of the other types when used in concrete are: Type II, moderate sulfate resistance or moderate heat of hydration; Type III, high early strength; Type IV, low heat of hydration; Type V, high sulfate resistance. The chemical and physical differences between the types that produce special properties lie in the proportions of the cement compounds and in the fineness to which the cement is ground (Table 1). A description and applications of various cement types, along with compressive strength acheived versus cure time, is given in Table 2.

Table 1. Approximate Composition and Fineness Ranges for ASTM Standard Types of Portland Cement

Compound/property	Composition, wt%/property value				
	Type I	Type II	Type III	Type IV	Type V
C_3S	42-65	35-60	45-70	20-30	40-60
C_2S	10-30	15-35	10-30	50-55	15-40
C_3A	0-17	0-8	0-15	3-6	0-5
C_4AF	6-18	6-18	6-18	8-15	10-18
CH_2	3-6	3-6	3-6	3-6	3-6
Specific surface area, m^2/kg (ft^2/lb)	300-400 (1465-1955)	280-380 (1365-1855)	450-600 (2195-2930)	280-320 (1365-1560)	290-350 (1415-1710)

Table 2. Compressive Strength Data for Typical Cements vs. Time

Cement type	Description	Applications
Type I	General use	Pavement, sidewalks, buildings, bridges, other structures, tanks
Type II	Moderate heat of hydration	Piers, heavy retaining walls
Type III	High early strength	Structures put into service quickly
Type IV	Low heat of hydration	Large gravity dams
Type V	Sulfate-resistant	Structures in areas with high sulfate levels
White portland	Limited iron content	Architectural applications
Portland/blast-furnace	Contains blast furnace slag	General construction applications

Cement type	Strength									
	1-day		3-day		7-day		28-day		91-day	
	MPa	ksi	MPa	ksi	MPa	ksi	MPa	ksi	MPa	ksi
Type I	9.3	1.3	22.5	3.3	32.0	4.6	42.0	6.1	50.5	7.3
Type II	14.0	2.0	27.0	3.9	36.6	5.3	46.3	6.7	52.5	7.6
Type III	21.0	3.0	37.5	5.4	44.2	6.4	52.3	7.6	56.0	8.1
Type IV	. . .	. . .	9.6	1.4	13.9	2.0	34.3	5.0	. . .	. . .

White portland	. . .	. . .	26.5	3.8	36.2	5.3	46.5	6.7	. . .	. . .
Portland/blast-furnace	8.6	1.2	13.1	1.9	25.3	3.7	45.0	6.5	53.3	. . .

Cement Pastes.—Cement and concrete technology have shown important advances in recent years. Two remarkable new products are densified with small particles (DSP) cement and macro-defect-free (MDF) cement. Both DSP and MDF cements are cement

www.EngineeringEBooksPdf.com

pastes rather than concretes, in that they do not contain aggregates. The DSP cements are pastes with low water-cement ratios that contain portland cement, fly ash, silica fume, water, and a superplasticizer. Low porosity is an important factor in helping them achieve compressive and flexural strengths that are unusually high for cementitious materials. The MDF cements also have low water-cement ratios, but they include a small quantity of polymeric material. They require special processing to avoid the inclusion of macrodefects such as air bubbles, and the best performance appears to be obtained using a calcium aluminate cement rather than a portland cement. Table 3 lists some mechanical properties of these materials.

Table 3. Mechanical Properties of Cements

Material	Strength MPa	Fracture toughness, MPa	Material	Strength MPa	Fracture toughness, MPa
Conventional cement paste	7–10	0.2–0.4	Glass-fiber-reinforced MDF cement	70–124	1.2–2.5
Conventional concrete	2–3	0.2	Polymer-fiber-reinforced MDF cement	54–120	1.7–2.8
Conventional fiber-reinforced concrete	6–13	5–21	Kevlar-fiber-reinforced MDF cement	58–128	2.1–5.3
High-strength concrete	8–11	0.7–1.5	Carbon-fiber-reinforced MDF cement	91–123	2.7–3.2
Densified-with-small-particles (DSP) cement	15–25	0.4–0.5	Aluminum-fiber-reinforced MDF cement	94–127	2.5–2.8

Use of Portland Cement.— Portland cement should be used for all structures which must withstand stresses and for masonry that is either under water or heavily exposed to water or the weather. According to the specifications of the American Society for Testing Materials, the specific gravity of Portland cement must be not less than 8:1. If the tested cement is below this requirement. A second test should be made on a sample ignited at a low red heat. The ignited cement should not lose more than four per cent of its weight. A satisfactory Portland cement must not develop initial set in less than 30 minutes; it must not develop hard set in less than 1 hour; but the time required for developing hard set must not exceed 10 hours. The minimum requirements for tensile strength in pounds, for briquettes one square inch in cross-section, should be as follows:

For cement 24 hours old in moist air, 175 pounds.

For cement 7 days old, one day in moist air and six days in water, 500 pounds.

For cement 28 days old, one day in moist air and 27 days in water, 600 pounds.

For one part of cement and three parts of standard Ottawa sand, 7 days old, one day in moist air and six days in water, 200 pounds.

For one part of cement and three parts of standard Ottawa sand, 28 days old, one day in moist air and 27 days in water, 275 pounds.

The cements must under no circumstances show a decrease in strength during the time periods specified.

Natural Cement.—Natural cement is used in mortar for ordinary brick work and stone masonry, street sub-pavements, as a backing or filling for massive concrete or stone masonry, and for similar purposes. Natural cement does not develop its strength as quickly and is not as uniform in composition as Portland cement. It should not be used for columns, beams, floors or any structural members which must withstand considerable stress. Natural cement is also unsuitable for work that is exposed to water. Foundations which are subjected to moderate compressive stresses may be made of natural cement, which is also satisfactory for massive masonry where weight rather than strength is the essential feature.

The American Society for Testing Materials gives the following specifications for natural cement: An initial set must not develop in less than 10 minutes, and the hard set must not develop in less than 30 minutes, but must develop in less than three hours. The minimum requirements for tensile strength in pounds, for briquettes one inch in cross-section, are as follows:

For natural cement 24 hours old in moist air, 75 pounds.

www.EngineeringEBooksPdf.com

For natural cement 7 days old, one day in moist air and six days in water, 150 pounds.
For natural cement 28 days old, one day in moist air and 27 days in water, 250 pounds.
For one part of cement and three parts of standard Ottawa sand, 7 days old, one day in moist air and six days in water, 50 pounds.
For one part of cement and three parts of standard Ottawa sand, 28 days old, one day in moist air and 27 days in water, 125 pounds.

Pozzuolanic or Slag Cement.—This cement is adapted for structures which are constantly exposed to fresh or salt water and for drains, sewers, foundation work underground, etc. It is not suitable where masonry is exposed to dry air for long periods. Pozzuolanic cement sets slowly but its strength increases considerably with age. While this cement is relatively cheap, it is not as strong, uniform, or reliable as Portland and natural cements, and is not used extensively.

Concrete

Concrete.—The principal ingredients of concrete are the matrix or mortar and the "coarse aggregate." The matrix consists of cement and sand mixed with water, and the coarse aggregate is usually broken stone or gravel. What is known as *rubble concrete* or cyclopean masonry contains large stones which are used for reducing the cost of massive dams and walls. These rubble stones may vary from a few per cent to over one-half the volume. When concrete without much strength but light in weight is required, cinders may be used. This cinder concrete is porous and is used for light floor construction or fire-proofing.

Concrete Mixtures.—In the mixing of concrete, it is desirable to use as little cement as is consistent with the required strength, because the cement is much more expensive than the other ingredients. The proportioning of the ingredients is usually by volume and mixtures are generally designated by giving the amount of each ingredient in a fixed order, as 1 : 2: 5, the first figure indicating the amount of cement by volume, the second the amount of sand, and the third the amount of broken stone or gravel.

For ordinary machine foundations, retaining walls, bridge abutments, and piers exposed to the air, a 1: 2½ : 5 concrete is satisfactory; and for ordinary foundations, heavy walls, etc., a lean mixture of 1 : 3: 6 may be used. For reinforced floors, beams, columns, and arches, as well as for machine foundations which are subjected to vibration, a 1 : 2 : 4 concrete is generally used. This composition is also employed when concrete is used under water. For water tanks and similar structures subjected to considerable pressure and required to be water-tight, mixtures rich in cement and composed of either 1 : 1 : 2 or 1 : 1½: 3 concrete are used. Portland cement should preferably be used in concrete construction.

Sand, Gravel, and Stone for Concrete.—The sand used must be free from dust, loam, vegetable, or other organic matter; it should pass, when dry, through a screen with holes of ¼-inch mesh. The gravel should consist of clean pebbles free from foreign matter and should be of such coarseness that it will not pass through a screen of ¼-inch mesh. Gravel containing loam or clay should be washed by a hose before mixing. The broken stone should be of a hard and durable kind, such as granite or limestone. This stone should pass through a 2½-inch screen.

Amount of Water for Mixing Concrete.—The amount of water required to combine chemically with cement is about 16 per cent by weight, but in mixing concrete a greater amount than this must be used, because of losses and the difficulty of uniformly distributing the water. In hot weather more water is required than in cool weather because of the loss due to evaporation. The same applies when absorbent sand is used, or when the concrete is not rammed tightly. An excess of water is not desirable, because this excess will flow away and carry some of the cement with it. The water must be free from oils, acids, and impurities that would prevent a proper chemical combination with the cement. It is important to

www.EngineeringEBooksPdf.com

mix the ingredients thoroughly. Lime cement, sand and stone should be mixed while dry, preferably using a machine. Enough water should then be added to produce a mixture which will flow readily and fill different parts of the form.

Reinforced Concrete.—Concrete reinforced with steel is widely used, especially where the concrete must resist tensile as well as compressive stresses. This reinforcement may be in the form of round bars twisted square bars, corrugated bars, expanded metal, steel mesh, or wire fabric. The proportions for reinforced concrete structures are usually 1 : 2 : 4, or 1 barrel of portland cement, 2 barrels of sand, and 4 barrels of broken stone or gravel. The lateral spacing between reinforcement bars should not be less than three times the bar diameter from center to center, with a clear space between the bars of at least one inch. The distance from the side of a beam to the center of the nearest bar should be not less than two diameters.

Strength of Concrete.—The strength varies greatly depending upon the quality and proportions of the ingredients and the care in mixing and depositing in the forms. The compressive strength of concrete which, after having been mixed and laid, has set 28 days, varies from 1000 to 3300 pounds per square inch, according to the mixture used. If made in the proportion 1 : 3 : 6, using soft limestone and sandstone a compressive strength of only 1000 pounds per square inch may be expected, whereas a mixture of 1 : 1 : 2, made with soft limestone and sandstone, will show a strength of 2200 pounds per square inch. A mixture of 1 : 3 : 6, made from granite or trap rock, will have a compressive strength of 1400 pounds per square inch, while a mixture of 1 : 1 : 2, made from granite or trap rock, will have a strength of 3300 pounds per square inch. Other mixtures will have values between those given. The richer in cement in proportion to sand, gravel, and stone, the stronger will be the concrete. The strongest concretes are also obtained by using granite or trap rock. A medium strength is obtained by using gravel, hard limestone, or hard sandstone, whereas the least strength is obtained by using soft limestone or sandstone. Concrete may also be mixed with cinders, but, in this case, very inferior strength is obtained; the richest mixtures will only give a strength of about 800 pounds per square inch.

Durability of Concrete in Sea Water.—Experiments have been made to determine the durability of different mixtures of concrete when exposed to sea water. It has been found that the mixtures that give the best results are those that are richest in cement. Mixtures of 1 : 1 : 2, for example, will give much better results than mixtures of 1 : 3 : 6. Also, very wet mixtures seem to give better results than those that are comparatively dry when deposited. It has also been found that, in order to insure the permanence of Portland cement concrete in sea water, the cement must contain as little lime and alumina as possible and must also be free from sulfates, and the proportion of sand and stones in the concrete must be such that the structure is practically non-porous. Natural cement should never be used for concrete exposed to sea water.

Waterproofing Concrete.—Several formulas for making concrete waterproof have been successfully used but some of them are too expensive for general application. One of the simplest, cheapest, and most effective is that developed by the U.S. Geological Survey. A heavy residual mineral oil of 0.93 specific gravity, mixed with Portland cement, makes it waterproof and does not weaken when the concrete consists of, say, cement, 1 part, sand, 3 parts, and oil, not more than 10 per cent, by weight, of the cement. Concrete mixed with oil requires about fifty per cent longer time to set hard, and the compressive strength is slightly decreased but not seriously. The bond or grip of oil concrete on steel is much decreased when plain bars are used, but formed bars, wire mesh, or expanded metal act as effectively in it as in ordinary concrete.

Resistance to Acids and Oils.—Concrete of a good quality, that has thoroughly hardened, resists the action of acids and mineral oils as well as other building materials, but vegetable oils containing fatty acids produce injurious effects by combining with the lime in the cement and causing disintegration of the concrete.

www.EngineeringEBooksPdf.com

Lutes and Cements

Luting and cementing materials for various purposes in the laboratory and shops may be classified as follows: water- and steam-proof; oil-proof; acid-proof; proof to hydrocarbon gases; chlorine-proof; elastic; general purposes; marine glue; gaskets; machinists; leather (belting); crucible; iron; and stone.

Water-proof Compositions.—The asphalt fluid coatings for reservoir wall, concrete foundations, brick, wood, etc., are often of use to engineers. Asphalt only partly dissolves in petroleum naphtha, but when heated in a steam-jacketed kettle and not thinned out too much, a mixture of the two may be obtained in which the part of the asphalt not dissolved is held in suspension. Asphalt is entirely soluble in benzol or toluol, which are about the cheapest solvents for all the constituents of asphalt. Tar and pitch are sometimes used in this connection, but tar contains water, light oils and free carbon, and does not wear as well as good refined asphalt; pitch also contains free carbon, which is sometimes objectionable when it is thinned out with a solvent. Asphalt alone is somewhat pervious to water, but it can be improved in this respect by adding about one-fourth its weight of paraffin; it is also well to add a little boiled linseed oil. For thicker compositions, where body is required, asbestos, stone powder, cement, etc., may be added as filters. Lutes of linseed oil thickened with clay, asbestos, red or white lead, etc., arc waterproof if made thick enough. These are much used for steam joints. Flaxseed meal made into a paste with water is often serviceable, the oil contained serving as a binder as the water evaporates.

Oil-proof Cements.—The well-known "hektograph composition" is the most useful lute for small leaks, etc. It consists of the following ingredients: Good glue or gelatin, 2 parts; glycerin, 1 part; water, 7 parts. This preparation is applied warm and stiffens quickly on cooling. Another very useful composition is a stiff paste of molasses and flour. Another preparation, impervious to oil vapors, is the "flaxseed poultice," mentioned in *Water-proof Compositions*, which is proof to oil vapors. One of the strongest cements, and one which is really oil-proof, waterproof and acid-proof, is a stiff paste of glycerin and litharge. These form a chemical combination which sets in a few minutes. If a little water is added, it sets more slowly, which is often an advantage. This cement is mixed when required for use. A mixture of plaster-of-paris and water is useful, and it is sometimes advantageous to mix straw or hair with it. A solution of silicate of soda made into a stiff paste with carbonate of lime gets hard in six to eight hours.

Acid-proof Cements.—The asphalt compositions already mentioned, compositions of melted sulphur with fillers of stone powder, cement, sand, etc., may be used, and also the following, which withstands hydrochloric acid vapors: rosin, 1 part; sulphur, 1 part; fireclay, 2 parts. The lute composed of boiled linseed oil and fireclay acts well with most acid vapors. The composition of glycerin and litharge previously referred to is useful in this connection, especially when made up according to the following formula: Litharge, 80 pounds; red lead, 8 pounds; "flock" asbestos, 10 pounds. It should be fed into a mixer, a little at a time, with small quantities of boiled oil (about six quarts of oil being used). Sockets in 3-inch pipes carrying nitric acid, calked with this preparation, showed no leaks in nine months.

A particularly useful cement for withstanding acid vapors, which is tough and elastic, is composed of crude rubber, cut fine, 1 part; linseed oil, boiled, 4 parts; fireclay, 6 parts. The rubber is dissolved in carbon disulphide to the consistency of molasses and is then mixed with the oil. Other acid-proof cements are as follows: "Black putty" made by carefully mixing equal portions of china-clay, gas-tar and linseed oil. The china-clay must be well dried by placing it over a boiler or by other means. Barytes cement is composed of pure, finely ground sulfate of barium, and is made into a putty with a solution of silicate of soda. This sets very hard when moderately heated, and is then proof against acids. The gravity of the silicate of soda should be between 1.2 and 1.4, 24 degrees to 42 degrees Baume. If too thin, it does not hold; and when thicker than 1.4, it expands and breaks.

www.EngineeringEBooksPdf.com

Gasket Compositions.— Almost any cementing substance may be used with rings of asbestos, etc., for gaskets, but some are especially adapted for the purpose. Asphalt, tar, petroleum residuum and soft or hard pitch are recommended. Silicate of soda is much used, and is sometimes advantageously mixed with casein, fine sand, clay, carbonate of lime, caustic lime, magnesia, oxides of heavy metals, such as lead, zinc, iron and powdered barytes. A few mixtures that might be selected are: Silicate of soda and asbestos; silicate of soda, asbestos and slaked lime; silicate of soda and fine sand; silicate of soda and fireclay.

Machinists Cements.— These are also known as red and white leads. The red lead is often diluted with an equal bulk of silica or other inert substance to make it less powdery. The best way to do this is to add rubber or gutta-percha to the oil as follows: Linseed oil, 6 parts, by weight; rubber or gutta-percha, 1 part by weight. The rubber or gutta-percha is dissolved in sufficient carbon disulphide to give it the consistency of molasses, mixed with the oil, and left exposed to the air for about twenty-four hours. The red lead is then mixed to a putty. Oxide of iron makes a less brittle cement than red lead.

Leather Cements.— a) Equal parts of good hide glue and American isinglass, softened in water for ten hours and then boiled with pure tannin until the whole mass is sticky. The surface of the joint should be roughened and the cement applied hot.

b) 1 pound of finely shredded gutta-percha digested over a water-bath with 10 pounds of benzol, until dissolved, and 12 pounds of linseed oil varnish stirred in.

c) 7 ½ pounds of finely shredded india-rubber is completely dissolved in 10 pounds of carbon disulphide by treating while hot; 1 pound of shellac and 1 pound of turpentine are added, and the hot solution heated until the two latter ingredients are also dissolved.

d) another leather cement is as follows: gutta-percha, 8 ounces; pitch, 1 ounce; shellac, 1 ounce; sweet oil, 1 ounce. These are melted together.

e) still another is as follows: fish glue is soaked in water twenty-four hours, allowed to drain for a like period, boiled well, and a previously melted mixture of 2 ounces of rosin and ½ ounce of boiled oil is added to every two pounds of glue solution.

Iron and Stone Cements.— When finely divided iron, such as filings or cast iron borings that have been powdered, is mixed with an oxidizing agent, such as manganese dioxide, or a substance electro-negative to iron, such as sulphur, in a good conducting solution like salt or sal-ammoniac, galvanic action sets in very rapidly and the iron swells, by forming iron oxide, and cements the mass together. It is best diluted with Portland cement, the proportions being as follows: iron filings, 40 parts; manganese dioxide or flowers of sulphur, 10 parts; sal-ammoniac, 1 part; Portland cement, 23 to 40 parts; water to form a paste. A hard stone-like composition is made as follows: zinc oxide, 2 parts; zinc chloride, 1 part; water to make a paste. Magnesium oxide and chloride may also be used in like proportions. When used in considerable quantity, this cement is mixed with powdered stone, for reasons of economy, the proportions depending upon the character of the work.

Cement Proof to Hydrocarbon Gases.— Compositions of plaster and cement, the former setting more quickly, are used; also compositions of casein, such as finely powdered casein, 2 parts; fresh slaked lime, 50 parts; fine sand, 50 parts. Water is added, when used, to form a thick mass. Various mixtures of silicate of soda are employed in which the thick silicate is absorbed in some inert material such as clay, sand or asbestos.

Cements Proof to Chlorine.— The best and only reliable compositions are a few made with Portland cement, and the following is used for electrolytic and chemical plants: powdered glass, 1 part; Portland cement, 1 part; silicate of soda, 1 part; a small amount of powdered slate. This lute withstands acids and alkalies, as well as the influences of chlorine. Linseed oil made into a paste with fireclay serves for a time.

Elastic Cements.— The various cements containing rubber are elastic, if the rubber is in a predominating amount; many containing boiled linseed oil and the hektograph composition, see *Oil-proof Cements*, are quite elastic. The rubber and linseed-oil cement, given in *Acid-proof Cements* on page 3367, is very tough and useful for nearly all purposes except

www.EngineeringEBooksPdf.com

when oil vapors are to be confined. The most useful single rubber lute is probably the so-called Hart's india-rubber cement. Equal parts of raw linseed oil and pure masticated rubber are digested together by heating, and this mixture is made into a stiff putty with fine "paper stock" asbestos. It is more convenient, however, to dissolve the rubber first in carbon disulphide, and, after mixing the oil with it, to let the solvent evaporate spontaneously.

General Purposes.—Plaster-of-paris, especially when mixed with straw, flush trimmings, hair, broken stone, etc., and used according to temperature strain and other conditions, is one of the most useful preparations for general purposes. A putty of flour and molasses is a good composition to keep in a works ready for quick application when needed. It serves, for a time, almost any purpose at moderate temperatures. Casein compositions have great strength. the white of an egg made into a paste with slaked lime is strong and efficient, but must be used promptly on account of its quick setting qualities.

Acid-proof Lining.—A lining for protecting tanks from the influence of acids is made from a mixture consisting of 75 parts (by weight), of pitch; 9 parts plaster-of-paris; 9 parts ochre; 15 parts beeswax; and 3 parts litharge. The tanks are covered on the inside with a thick coat of this mixture.

Cements for Pipe Joints.—A strong cement which is oil-proof, waterproof, and acid-proof, consists of a stiff paste of glycerin and litharge. These form a chemical combination which sets in a few minutes. If a little water is added, it sets more slowly, which is often an advantage. This cement is mixed when required for use.

Mixture for Threaded Pipe Joints: A good material to apply to pipe threads before making up the joints, in order to obtain a tight joint that will resist the action of gases or liquids, is made of red lead mixed with pure boiled linseed oil. This mixture has been widely used and is very satisfactory. It should have a heavy fluid-like consistency, and if applied to a clean, well-cut thread will give an excellent joint.

Shellac for Pipe Connections: Shellac has proved to be a very satisfactory substitute for lead in sealing air and gas pipe connections. It is applied with a brush to the joints and hardens very rapidly, and being brittle, the pipes can be readily disconnected.

Graphic, Litharge, Chalk Cement: A good cement for use in making steam pipe joints is made in the following manner: Grind and wash in clean cold water 15 parts of chalk and 50 parts of graphite; mix the two together thoroughly and allow to dry. When dry regrind to a fine powder, to which add 20 parts of ground litharge and mix to a stiff paste with 15 parts of boiled linseed oil. The preparation may be set aside for future use, as it will remain plastic for a long time if placed in a cool place. It is applied to the joint packing as any ordinary cement.

White and Red Lead Mixture: Mix in ordinary white lead, enough powdered red lead to make a paste the consistency of putty. Spread this mixture on the joint, and when it hardens, the joint will be water tight. This mixture was used on stand-pipe flanges after testing all kinds of rubber gaskets without success. The mixture hardened and made a tight joint, never leaking afterward.

Adhesives and Sealants

Adhesives Bonding.—By strict definition, an adhesive is any substance that fastens or bonds materials to be joined (adherends) by means of surface attachment. However, besides bonding a joint, an adhesive may serve as a seal against attack by or passage of foreign materials. When an adhesive performs both bonding and sealing functions, it is usually called an adhesive sealant.

Where the design of an assembly permits, bonding with adhesives can replace bolting, welding, and riveting. When considering other fastening methods for thin cross-sections, the joint loads might be of such an unacceptable concentration that adhesives bonding may provide the only viable alternative. Properly designed adhesive joints can minimize or

www.EngineeringEBooksPdf.com

eliminate irregularities and breaks in the contour of an assembly. Adhesives can also serve as dielectric insulation. An adhesive with dielectric properties can act as a barrier against galvanic corrosion when two dissimilar metals such as aluminum and magnesium are joined together. Conversely, adhesive products are available which also conduct electricity.

An adhesive can be classified as structural or non-structural. Agreement is not universal on the exact separation between both classifications. But, in a general way, an adhesive can be considered structural when it is capable of supporting heavy loads; non-structural when it cannot. Most adhesives are found in liquid, paste, or granular form, though film and fabric-backed tape varieties are available. Adhesive formulations are applied by brush, roller, trowel, or spatula. If application surfaces are particularly large or if high rates of production are required, power-fed flow guns, brushes, or sprays can be used.

The hot-melt adhesives are relatively new to the assembly field. In general, they permit fastening speeds that are much greater than water- or solvent-based adhesives. Supplied in solid form, the hot-melts liquefy when heated. After application, they cool quickly, solidifying and forming the adhesive bond. They have been used successfully for a wide variety of adherends, and can greatly reduce the need for clamping and lengths of time for curing storage.

If an adhesive bonding agent is to give the best results, time restrictions recommended by the manufacturer, such as shelf life and working life must be observed. The shelf life is considered as the period of time an adhesive can be stored after its manufacture. Working or "pot" life is the span of time between the mixing or making ready of an adhesive, on the job, and when it is no longer usable.

The actual performance of an adhesive-bonded joint depends on a wide range of factors, many of them quite complex. They include: the size and nature of the applied loads; environmental conditions such as moisture or contact with other fluids or vapors; the nature of prior surface treatment of adherends; temperatures, pressures and curing times in the bonding process.

A great number of adhesives, under various brand names, may be available for a particular bonding task. However, there can be substantial differences in the cost of purchase and difficulties in application. Therefore, it is always best to check with manufacturers' information before making a proper choice. Also, testing under conditions approximating those required of the assembly in service will help assure that joints meet expected performance.

Though not meant to be all-inclusive, the information which follows correlates classes of adherends and some successful adhesive compositions from the many that can be readily purchased.

Bonding Metal: Epoxy resin adhesives perform well in bonding metallic adherends. One type of epoxy formulation is a two-part adhesive which can be applied at room temperature. It takes, however, seven days at room temperature for full curing, achieving shear strengths as high as 2500 psi (17.2 MPa). Curing times for this adhesive can be greatly accelerated by elevating the bonding temperature. For example, curing takes only one hour at 160°F (71°C).

A structural adhesive-filler is available for metals which is composed of aluminum powder and epoxy resin. It is made ready by adding a catalyst to the base components, and can be used to repair structural defects. At a temperature of 140°F (60°C) it cures in approximately one hour. Depending on service temperatures and design of the joint, this adhesive-filler is capable of withstanding flexural stresses above 10,000 psi (69 MPa), tension above 5,000 psi (34 MPa), and compression over 30,000 psi (207 MPa).

Many non-structural adhesives for metal-to-metal bonding are also suitable for fastening combinations of types of materials. Polysulfide, neoprene, or rubber-based adhesives are used to bond metal foils. Ethylene cellulose cements, available in a selection of colors, are used to plug machined recesses in metal surfaces, such as with screw insets. They harden

www.EngineeringEBooksPdf.com

within 24 hours. Other, stronger adhesive fillers are available for the non-structural patching of defects in metallic parts. One variety, used for iron and steel castings, is a cement that combines powdered iron with water-activated binding agents. The consistency of the prepared mix is such that it can be applied with a trowel and sets within 24 hours at room temperature. The filler comes in types that can be applied to both dry and wet castings, and is able to resist the quick changes of temperature during quenching operations.

Polyester cement can replace lead and other fillers for dents and openings in sheet metal. One type, used successfully on truck and auto bodies, is a two-part cement consisting of a paste resin that can be combined with a paste or powder extender. It is brushed or trowelled on, and is ready for finishing operations in one hour.

Adhesives can be used for both structural and non-structural applications which combine metals with non-metals. Structural polyester-based adhesives can bond reinforced plastic laminates to metal surfaces. One type has produced joints, between glass reinforced epoxy and stainless steel, that have tensile strengths of over 3000 psi (21 MPa). Elevated temperature service is not recommended for this adhesive. However, it is easily brushed on and bonds under slight pressure at room temperature, requiring several days for curing. The curing process accelerates when heat is added in a controlled environment, but there results a moderate reduction in tensile strength.

Low-density epoxy adhesives are successful in structurally adhering light plastics, such as polyurethane foam, to various metals. Applied by brush or spatula, the bonds cure within 24 hours at room temperatures

Metals can be bonded structurally to wood with a liquid adhesive made up of neoprene and synthetic resin. For the best surface coverage, the adhesive should be applied in a minimum of two coats. The joints formed are capable of reaching shear stresses of 125 psi, and can gain an additional 25 percent in shear strength with the passage of time. This adhesive also serves as a strong, general purpose bonding agent for other adherend combinations, including fabrics and ceramics.

For bonding strengths in shear over 500 psi (3.4 MPa) and at service temperatures slightly above 160°F (71°C), one- and two-part powder and jelly forms of metal-to-wood types are available.

Besides epoxy formulations, there are general purpose rubber, cellulose, and vinyl adhesives suitable for the non-structural bonding of metals to other adherends, which include glass and leather. These adhesives, however, are not limited only to applications in which one of the adherends is metal. The vinyl and cellulose types have similar bonding properties, however the vinyls are less flammable and are weaker in resistance to moisture than the comparable cellulosics. Rubber-based adhesives, in turn, have good resistance to moisture and lubricating oil. They can form non-structural bonds between metal and rubber.

One manufacturer has produced an acrylic-based adhesive that is highly suitable for rapidly bonding metal with other adherends at room temperature. For some applications it can be used as a structural adhesive, in the absence of moisture and high temperature. It cures within 24 hours and can be purchased in small bottles with dispenser tips.

A two-part epoxy adhesive is commercially available for non-structural bonding of joints or for patchwork in which one of the adherends is metal. Supplied in small tubes, it performs well even when temperatures vary between –50° to 200°F (–46° to 93°C). However, it is not recommended for use on assemblies that may experience heavy vibrations.

Bonding Plastic: Depending on the type of resin compound used in its manufacture, a plastic material can be classified as one of two types: a thermoplastic or a thermoset.

Thermoplastic materials have the capability of being repeatedly softened by heat and hardened by cooling. Common thermoplastics are nylon, polyethylene, acetal, polycarbonate, polyvinyl chloride, cellulose nitrate and cellulose acetate. Also, solvents can easily dissolve a number of thermoplastic materials. Because of these physical and chemical

www.EngineeringEBooksPdf.com

characteristics of thermoplastics, heat or solvent welding may in many instances offer a better bonding alternative than adhesives.

Thermoplastics commonly require temperatures between 200° and 400°F (93° and 204°C) for successful heat welding. However, if the maximum temperature limit for a particular thermoplastic formulation is exceeded, the plastic material will experience permanent damage. Heat can be applied directly to thermoplastic adherends, as in hot-air welding. More sophisticated joining techniques employ processes in which the heat generated for fusing thermoplastics is activated by electrical, sonic, or frictional means.

In the solvent welding of thermoplastics, solvent is applied to the adherend surfaces with the bond forming as the solvent dries. Some common solvents for thermoplastics are: a solution of phenol and formic acid for nylon; methylene chloride for polycarbonate; and methyl alcohol for the cellulosics.

Many adhesive bonding agents for thermoplastics are "dope" cements. Dope or solvent cements combine solvent with a base material that is the same thermoplastic as the adherend. One type is used successfully on polyvinyl chloride water (PVC) pipe. This liquid adhesive, with a polyvinyl chloride base, is applied in at least two coats. The pipe joint, however, must be closed in less than a minute after the adhesive is applied. Resulting joint bonds can resist hydrostatic pressures over 400 psi (28 MPa), for limited periods, and also have good resistance to impact.

Previously mentioned general purpose adhesives, such as the cellulosics, vinyls, rubber cements, and epoxies are also used successfully on thermoplastics.

Thermoset plastics lack the fusibility and solubility of the thermoplastics and are usually joined by adhesive bonding. The phenolics, epoxies, and alkyds are common thermoset plastics. Epoxy-based adhesives can join most thermoset materials, as can neoprene, nitrile rubber, and polyester-based cements. Again, these adhesives are of a general purpose nature, and can bond both thermoplastics and thermosets to other materials which include ceramics, fabric, wood, and metal.

Bonding Rubber: Adhesives are available commercially which can bond natural, butyl, nitrile, neoprene, and silicone rubbers. Natural and synthetic rubber cements will provide flexible joints; some types resist lubricating and other oils. Certain general purpose adhesives, such as the acrylics or epoxies, can bond rubber to almost anything else, though joints will be rigid. Depending on the choice of adhesive as well as adherend types, the bonds can carry loadings that vary from weak non-structural to mild structural in description. One type of natural rubber with a benzene-naphtha solvent can resist shear stresses to 1252.5 psi (83 kPa).

Bonding Wood: Animal glues, available in liquid and powder form, are familiar types of wood-to-wood adhesives, commonly used in building laminated assemblies. Both forms, however, require heavy bonding pressures for joints capable of resisting substantial loadings. Also, animal glues are very sensitive to variations in temperature and moisture.

Casein types of adhesive offer moderate resistance to moisture and high temperature, but also require heavy bonding pressures, as much as 200 psi, for strong joints. Urea resin adhesives also offer moderate weather resistance, but are good for bonding wood to laminated plastics as well as to other wooden adherends. For outdoor service, under severe weather conditions, phenol-resorcinol adhesives are recommended.

Vinyl-acetate emulsions are excellent for bonding wood to other materials that have especially non-porous surfaces, such as metal and certain plastic laminates. These adhesives, too, tend to be sensitive to temperature and moisture, but are recommended for wooden pattern making.

Rubber, acrylic, and epoxy general-purpose adhesives also perform well with wood and other adherend combinations. Specific rubber-based formulations resist attack by oil.

Fabric and Paper Bonding: The general purpose adhesives, which include the rubber cements and epoxies previously mentioned, are capable of bonding fabrics together and

www.EngineeringEBooksPdf.com

fabrics with other adherend materials. A butadiene-acrylonitrile adhesive, suitable also for fastening metals, glass, plastic, and rubber, forms joints in fabric that are highly resistant to oil and which maintain bonding strength at temperatures up to 160°F (70°C). This adhesive, however, requires a long curing period, the first few hours of which are at an elevated temperature.

Commonly, when coated fabric materials must be joined, the base material forming the suitable adhesive is of the same type as that protecting the fabric. For example, a polyvinyl chloride-based adhesive is acceptable for vinyl-coated fabrics; and neoprene-based cements for neoprene-coated materials.

Rubber cements, gum mucilages, wheat pastes, and wood rosin adhesive can join paper as well as fabric assemblies. Solvent-based rosins can be used on glass and wood also. Rosin adhesives can also be treated as hot-melt adhesives for rapid curing. Generally, the rosins are water resistant, but usually weak against attack by organic solvents.

Sealants.—Normally, the primary role of a sealant composition is the prevention of leakage or access by dust, fluid, and other materials in assembly structures. Nevertheless, many products are currently being manufactured that are capable of performing additional functions. For example, though a sealant is normally not an adhesive, there exists a family of adhesive sealants which in varying degrees can bond structural joints as well. Besides resisting chemical attack, some sealant surface coatings can protect against physical wear. Sealants can also dampen noise and vibration, or restrict the flow of heat or electricity. Many sealant products are available in decorative tints that can help improve the appearance of an assembly.

Most sealants tend to be limited by the operating temperatures and pressures under which they are capable of sustained performance. Also, before a suitable choice of sealant formulation is made, other properties have to be examined; these include: strength of the sealant; its degree of rigidity; ease of repair; curing characteristics; and even shelf and working life.

Dozens of manufacturers supply hundreds of sealant compounds, a number of which may fill the requirements for a particular application. The following information, however, lists common uses for sealants, along with types of compositions that have been employed successfully within each category.

Gasket Materials: Silicone rubber gasket compositions are supplied in tubes in a semiliquid form ready for manual application. They can also be obtained in larger containers for power-fed applications. Suppliers offer a silicone rubber-based composition that can replace preformed paper, cork, and rubber gaskets for many manufacturing operations. This composition has performed successfully in sealing water pumps, engine filter housings, and oil pans. It can also seal gear housings and other joints that require a flexible gasket material that besides resisting shock can sustain large temperature changes. Silicone rubber compositions can withstand temperatures that vary from –100°F to 450°F (–73°C to 232°C).

Gasket tapes, ropes, and strips can also be readily purchased to fit many assembly applications. One type of sealant tape combines a pressure-sensitive adhesive with a strip of silicone-rubber sponge. This tape has good cushioning properties for vibration damping and can stick to metal, plastic, ceramic, and glass combinations.

TFE-based gasketing strips are also available. This non-stick gasketing material can perform at pressures up to 200 psi (1.4 MPa) and temperatures to 250°F (120°C). Because of the TFE base, the strip does not adhere to or gum joint surfaces.

Sealing Pipe Joints: Phenolic-based sealants can seal threaded joints on high-pressure steam lines. One type, that is available in liquid or paste form, resists pressure up to 1200 psi (8.3 MPa) and temperatures to 950°F (510°C). This compound is brushed on and the joint closed and tightened to a torque of 135 in.-lb. (15.3 N m). The connection is then subjected to a 24-hour cure with superheated steam.

www.EngineeringEBooksPdf.com

The joining and sealing of plastic pipe is covered under the previous adhesives bonding section.

Sulfur-based compounds, though lacking the durability of caulking lead, can be used on bell and spigot sewer pipe. Available in a formulation that can resist temperatures up to 200°F (93°C), one sulfur-based sealant is applied as a hot-melt and allowed to flow into the bell and spigot connection. It quickly solidifies at room temperature, and can develop a joint tensile strength over 300 psi (2.1 MPa).

There are asphalt, coal-tar and plastic-based compositions that can be used on both cast-iron and ceramic bell and spigot pipe. Portland cement mortars also seal ceramic piping.

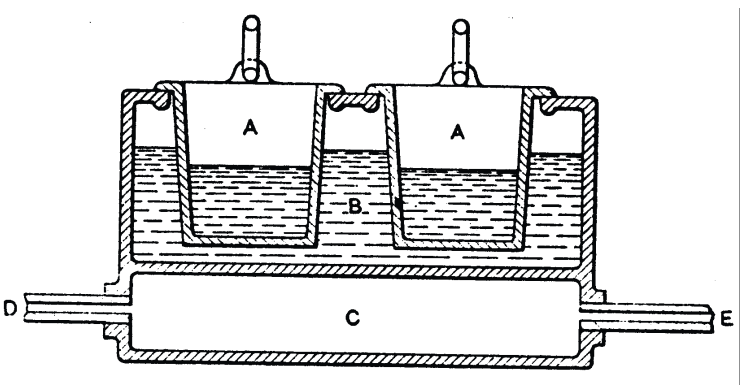
Waterproof Compositions.—The asphalt fluid coatings for reservoir walls, concrete foundations, brick, wood, etc., are often of use to engineers. Asphalt only partly dissolves in petroleum naphtha, but when heated in a steam-jacketed kettle and not thinned out too much, a mixture of the two may be obtained in which the part of the ashpalt not dissolved is held in suspension. Asphalt is entirely soluble in benzol or toluol, which are about the cheapest solvents for all the constituents of asphalt. Tar and pitch are sometimes used in this connection, but tar contains water, light oils, and free carbon, and does not wear as well as good refined asphalt; pitch also contains free carbon, which is sometimes objectionable when it is thinned out with a solvent. Asphalt alone is somewhat pervious to water, but it can be improved in this respect by adding about one-fourth its weight of paraffin; it is also well to add a little boiled linseed oil. For thicker compositions, where body is required, asbestos, stone powder, cement, etc., may be added as fillers. Lutes of linseed oil thickened with clay, asbestos, red or white lead, etc., are waterproof if made thick enough. These are much used for steam joints. Flaxseed meal made into a paste with water is often serviceable, the oil contained serving as a binder as the water evaporates.

Marine Glue.—Marine glue, proof against the action of salt water, consists of 1 part of crude rubber, 2 parts of shellac, and 3 parts of pitch. The rubber is first dissolved in carbon disulphide or turpentine, and is then mixed with the heated combination of the two other ingredients.

Glues for Wood.—The glues that are adapted for gluing wood according to a report of the Forest Products Laboratory, U. S. Forest Service, Madison, Wis., may be conveniently divided into nve classes as follows:

1. Animal glues, which are made from the hides, hoofs, horns, bones, and fleshings of animals, mostly cattle. These glues come in dry form, and must be mixed with water and melted.

2. Casein glues, which are made from casein, lime, and certain other chemical ingredients. They are commonly sold in prepared form, requiring only the addition of water, but may be mixed by the addition of the separate materials to the water.



Steam Glue Heater

www.EngineeringEBooksPdf.com

3. Vegetable glues, which are made from starch, usually cassava starch, and sold in powdered form. They may be mixed cold with water and alkali, but heat is commonly used in their preparation.

4. Blood-albumin glues, which are made from soluble blood albumin, a product recovered from the blood of animals. These glues must be mixed just before use, since they deteriorate rapidly on standing.

5. Liquid glues, which are commonly made from the heads, skins, bones, and swimming bladders of fish. Some liquid glues are made from animal glue and from other materials. They come in prepared form ready for immediate use.

Animal Glue: Animal glue, frequently referred to as "hotglue," is familiar to all woodworkers. The principal desirable properties of animal glue are its great strength and reliability in the higher grades, its free-flowing consistency, and the fact that it does not stain wood. So far no glue has been found to be as suitable as animal glue for handspreading on irregular shaped joints. The price of animal glue is the chief factor that limits its use. The fact that it is not highly water-resistant is occasionally a drawback.

Casein Glue: Casein glue has sufficient strength for either veneer or joint work. It is used cold, and when properly mixed it can be spread with a brush. The property most featured is its high water-resistance, which makes it suitable for gluing articles to be used under moist conditions. Not all casein glues are water-resistant, however; there are some on the market which are made to compete with vegetable glue, and for which no great water-resistance is claimed. Among the disadvantages of casein glues are their tendency to stain thin veneer and the relatively short working life of some kinds. It is claimed that this trouble has been overcome to a certain extent in some glues. They are somewhat harder on tools than animal and vegetable glues.

Vegetable Glue: Vegetable glues have found wide use because they are cheap, can be used cold, and remain in good working condition free from decomposition for many days. They are extremely viscous, and it is not practicable to spread them by hand. Their lack of water-resistance and the fact that they usually cause staining in thin fancy veneer are factors limiting their use. They set relatively slowly, and for this reason are not so well adapted for joint work.

Blood-albumin Glue: Blood-albumin glue has shown notably high resistance to moisture, especially in the boiling test. This makes it particularly suitable for gluing plywood which is later to be softened in hot water and molded. The production of molded plywood articles has been very limited, but it offers a good field tor future development. In the past the chief drawback to the use of blood glues has been the necessity for hot-pressing, but tests have shown that a highly water-resistant blood glue may be developed which can be cold-pressed successfully.

Liquid Glue: Liquid glues are, in general, similar in properties to animal glue. Some brands are quite equal in strength to good joint glues, but other brands are very weak and unreliable. Their great advantage is that they come in prepared form, ready for immediate use. This makes them particularly suitable for patch work and small gluing jobs. The factors that limit their use are their high price, their lack of water-resistance, and the difficulty in distinguishing between good and poor brands.

Veneer and Joint Glues: Generally speaking, present vegetable and blood-albumin glues are veneer glues, while animal and casein glues are used both as veneer and as joint glues. As between animal and casein glue for joint work, if freedom from staining is important, animal glue is preferable; if water-resistance is of importance, then a casein glue should be selected. Because of the necessity of heat in the preparation and use of animal glue, the casein cold glue will probably be favored if both glues are otherwise equally well adapted.

Rust Prevention.—When the atmosphere, sea water, acids. or similar substances with which iron or steel comes into contact, attack the iron by forming oxides or rust upon its surface, corrosion is said to take place. Iron and steel cannot stand exposure to the atmosphere, particularly when excessive moisture is contained in the air, for any length of time,

www.EngineeringEBooksPdf.com

without the protection of some covering or coating which excludes the moisture and which, in itself, is not attacked by the influence of the atmosphere. The various preventives which follow have been recommended by different men in the mechanical field.

Resin and Oil: Melt 4 ounces of resin in 1 quart of linseed oil and mix with 2 gallons of kerosene oil. The mixture is readily applied with a cloth or brush, and can be easily removed.

Caoutchouc, Turpentine and Oil: To preserve steel from rust, dissolve 1 part caoutchouc and 16 parts turpentine with a gentle heat, then add 8 parts boiled oil, and mix by bringing them to the heat of boiling water. Apply to the steel with a brush, the same as varnish. It can be removed again with a cloth soaked in turpentine.

Varnish and Turpentine: To make a mixture that will prevent hardware and machinists' tools from rusting, take one-half pint of Demar white varnish and mix it well with one gallon of turpentine. When the polished surfaces are thoroughly covered with a thin coat, the varnish will scarcely show, but will preserve the polish for years, if it is not scraped off with something very hard.

Vaseline and Blue Ointment: In one pound of vaseline melt 2 ounces of blue ointment-what druggists call one-third-and add, to give it a pleasant odor, a few drops of oil of wintergreen, cinnamon, or sassafras. When thoroughly mixed, pour into a tin can.

Alcohol and Sperm Oil: To make a preservative oil, use high test grain alcohol and best grade of sperm oil, equal parts. Keep in a tightly-corked bottle, and shake well before using, as the alcohol and oil separate after standing. Any moisture on a tool or gun at the time of application is quickly absorbed by the alcohol, which in a short time evaporates, leaving a good coat of sperm oil to protect the surface from rust.

Soda Solution: Rust formation takes place on tools within a few hours after they have been hardened in brine or in any of the numerous hardening solutions containing different salts used for this purpose. To counteract this rusting of tools, they should be boiled in a strong solution of soda water for fifteen or twenty minutes after having been hardened. Sal soda (common washing soda) is the kind to use for the solution. A kettle holding about six or eight gallons of water may be used. About five pounds of soda are put in at the start, and after that about one to one and one-half pounds is added every day. In this way the strength of the solution is kept about right.

The addition of soda is necessary on account of the overflow which is required because of the method used for heating, the solution being brought to the boiling point by introducing steam. The work should always be boiled before being put into the tempering furnace and the latter should be at a temperature of about 212 degrees F., when the tools are changed from the soda kettle to the furnace. A basket arrangement with windlass may be used for raising and lowering the work, to prevent scalding the hands. The direction given, if followed, will prove of advantage in hardening and tempering tools, in that the formation of rust will be prevented.

Oil and Graphite: To prevent screws from getting rusty and sticking tight, instead of using ordinary oil only, add some graphite. After years you will be able to unscrew them with ease, and find them as bright as new, even if they have been exposed to very damp air.

Camphor, Lard and Black Lead: A formula for an anti-rust compound is made as follows: Dissolve 1 ounce of camphor in 1 pound of melted lard; take off the scum, and mix in as much fine black lead as will give it color. Clean the machinery, and smear it with the mixture, and after 24 hours rub clean with a soft linen cloth. The machinery will keep clean, under ordinary circumstances, for a long time.

White Lead and Tallow: In order to keep white lead and tallow soft in winter and summer alike, so that it can be applied with a brush to finished parts of machinery before shipping them, and for use in fitting keys, etc., prepare a mixture composed of five pounds of white lead and fifteen pounds of tallow. Heat this in a suitable receptacle, and stir until the ingredients are thoroughly mixed. Then remove the mixture to a cool place, and add two quarts of linseed oil, continuing to stir the composition until it becomes cold, as otherwise the

www.EngineeringEBooksPdf.com

white lead will settle at the bottom. This mixture will always remain of the same consistency at all temperatures.

Red-lead Paint for Structural Steel: Structural steel is generally protected from rust by painting. A rust-retarding coat of paint may be suitably compounded from red lead mixed with pure linseed oil. The average stock mixture consists of from 25 to 30 pounds of red lead to a gallon of oil. This mixture can be reduced to the proper consistency at the time of application. A small amount of turpentine added to this brush coating will greatly assist in its manipulation, and will also provide for proper penetration. Red lead should be mixed at the time of its application, as it settles quite readily, being an extremely heavy pigment.

Keys and Keyways

British Standard Metric Keys and Keyways.—This British Standard, BS 4235:Part 1:1972 (R1986), covers square and rectangular parallel keys and keyways, and square and rectangular taper keys and keyways. Plain and gib-head taper keys are specified. There are three classes of fit for the square and rectangular parallel keys and keyways, designated free, normal, and close. A *free fit* is applied when the application requires the hub of an assembly to slide over the key; a *normal fit* is employed when the key is to be inserted in the keyway with the minimum amount of fitting, as may be required in mass-production assembly work; and a *close fit* is applied when accurate fitting of the key is required under maximum material conditions, which may involve selection of components.

The Standard does not provide for misalignment or offset greater than can be accommodated within the dimensional tolerances. If an assembly is to be heavily stressed, a check should be made to ensure that the cumulative effect of misalignment or offset, or both, does not prevent satisfactory bearing on the key. Radii and chamfers are not normally provided on keybar and keys as supplied, but they can be produced during manufacture by agreement between the user and supplier.

Unless otherwise specified, keys in compliance with this Standard are manufactured from steel made to BS 970 having a tensile strength of not less than 550 MN/m^2 in the finished condition. BS 970, Part 1, lists the following steels and maximum section sizes, respectively, that meet this tensile strength requirement: 070M20, 25×14 mm; 070M26, 36×20 mm; 080M30, 90×45 mm; and 080M40, 100×50 mm.

At the time of publication of this Standard, the demand for metric keys was not sufficient to enable standard ranges of lengths to be established. The lengths given in the accompanying table are those shown as standard in ISO Recommendations R773: 1969, "Rectangular or Square Parallel Keys and their Corresponding Keyways (Dimensions in Millimeters)," and R 774: 1969, "Taper Keys and their Corresponding Keyways—with or without Gib Head (Dimensions in Millimeters)."

Tables 1 through 4 on the following pages cover the dimensions and tolerances of square and rectangular keys and keyways, and square and rectangular taper keys and keyways. Table 5 on page 3382 provides preferred lengths of metric keys.

[a] The tolerance on the width and thickness of square taper keys is h9, and on the width and thickness of rectangular taper keys, h9 and h11 respectively, in accordance with ISO metric limits and fits. Does not apply to gib head dimensions.

British Standard Keys and Keyways, Inch.—Tables 6 through 11 from BS 46:Part 1:1958 (1985) (obsolescent) provide data for rectangular parallel keys and keyways, square parallel keys and keyways, plain and gib head rectangular taper keys and key-ways, plain and gib head square taper keys and keyways, and Woodruff keys and keyways.

Parallel Keys: These keys are used for transmitting unidirectional torques in transmissions not subject to heavy starting loads and where periodic withdrawal or sliding of the hub member may be required. In many instances, particularly couplings, a gib-head cannot be accommodated, and there is insufficient room to drift out the key from behind. It is then necessary to withdraw the component over the key and a parallel key is essential. Parallel square and rectangular keys are normally side fitting with top clearance and are usually retained in the shaft rather more securely than in the hub. The rectangular key is the gen-

eral-purpose key for shafts greater than 1 inch in diameter; the square key is intended for use with shafts up to and including 1-inch diameter or for shafts up to 6-inch diameter where it is desirable to have a greater key depth than is provided by rectangular keys. In stepped shafts, the larger diameters are usually required by considerations other than torque, e.g., resistance to bending. Where components such as fans, gears, impellers, etc., are attached to the larger shaft diameter, the use of a key smaller than standard for that diameter may be permissible. As this results in unequal disposition of the key in the shaft and its related hub, the dimensions H and h must be recalculated to maintain the $T/2$ relationship.

Taper Keys: These keys are used for transmitting heavy unidirectional, reversing, or vibrating torques and in applications where periodic withdrawal of the key may be necessary. Taper keys are usually top fitting, but may be top and side fitting where required, and the keyway in the hub should then have the same width value as the keyway in the shaft. Taper keys of rectangular section are used for general purposes and are of less depth than square keys; square sections are for use with shafts up to and including 1-inch diameter or for shafts up to 6-inch diameter where it is desirable to have greater key depth.

Dimensions and Tolerances for British Parallel and Taper Keys and Keyways: Dimensions and tolerances for key and keyway widths given in Tables 6, 7, 8, and 9 are based on the width of key W and provide a fitting allowance. The fitting allowance is designed to permit an interference between the key and the shaft keyway and a slightly easier condition between the key and the hub keyway. In shrink and heavy force fits, it may be found necessary to depart from the width and depth tolerances specified. Any variation in the width of the keyway should be such that the greatest width is at the end from which the key enters and any variation in the depth of the keyway should be such that the greatest depth is at the end from which the key enters.

Keys and keybar normally are not chamfered or radiused as supplied, but this may be done at the time of fitting. Radii and chamfers are given in Tables 6, 7, 8, and 9. Corner radii are recommended for keyways to alleviate stress concentration.

Woodruff Keys.—In the Woodruff key system, half-circular disks of steel are used as keys, the half-circular side of the key being inserted into the keyseat. Part of the key projects and enters into a keyway in the part to be keyed to the shaft in the ordinary way. The advantage of this method of keys is that the keyway is easily milled by simply sinking a milling cutter, of the same diameter as the diameter of the stock from which the keys are made, into the shaft. The keys are also very cheaply made, as they are simply cut off from round bar stock and milled apart in the center. Dimensions of Woodruff keys are given in engineering handbooks.

These keys are used for light applications or the angular location of associated parts on tapered shaft ends. They are not recommended for other applications, but if so used, corner radii in the shaft and hub keyways are advisable to reduce stress concentration.

Dimensions and Tolerances of British Woodruff Keys and Keyways: Dimensions and tolerances are shown in Table 11. An optional alternative design of the Woodruff key that differs from the normal form in its depth is given in the illustration accompanying the table. The method of designating British Woodruff Keys is the same as the American method explained in the footnote on page 2478.

Key.—A key of the type commonly used in machine construction consists ordinarily of a piece of steel, either square or rectangular in cross-section, which is inserted into a keyway or keyseat formed partly in a shaft and partly in the hub of a gear, pulley, or other part which, by means of the key, is driven positively and prevented from rotating relative to its shaft. While keys are used primarily to prevent relative rotation between shafts and such parts as pulleys, gears, etc., they also prevent axial movement in many cases, owing to the frictional resistance between the keyed parts. The type of key that may properly be employed in any case naturally depends somewhat upon the class of work for which it is intended.

The draw or *gib key* is a sunk key which has a head by means of which it can be removed. The *round tapered key* is simply a taper pin which is driven into a hole that is partly in the shaft and partly in the hub; this form is used for light work. The name *feather* or *spline* is applied to a key which is fixed to either a shaft or hub, as when a gear must be driven by a shaft, but at the same time be free to slide in a lengthwise direction. The *Woodruff key* is a section of a disk, the part which enters the shaft being circular.

Sunk Key.—A sunk key, as its name implies, is sunk into a shaft. With this type of key, which is the one most commonly used, care should be taken to secure a good bearing on the sides. Ordinarily, the bearing at the top and bottom of a sunk key should be comparatively light, although, in some cases, when it is used to resist endwise movement, as well as a rotary movement, it is given a heavy bearing on all sides. The principal bearing, however, should not be, in any case, at the top and bottom, as it is then more likely to work loose than when fitted tightly at the sides.

The width of an ordinary sunk key ordinarily is equal to about one-fourth of the shaft diameter and the thickness, when a flat key is preferred to the square form, is usually about one-sixth of the shaft diameter; these proportions are varied somewhat by different manufacturers. The taper of American Standard square and flat keys is $\frac{1}{8}$ inch per foot.

Saddle Key.—The so-called *saddle key* does not enter a slot in the shaft. This form of key has parallel sides and is curved on its under side to fit the shaft. it is slightly tapered on top so that, when it is driven tightly in place, the shaft is held by frictional resistance. This key should be fitted so that it bears lightly on the sides and heavily between the shaft and hub throughout its entire length. As the drive with this type of key is not positive, it is only used where there is little power to transmit. It is an inexpensive method of keying, as the shaft does not need to be machined.

Flat Key.—The *flat key* is a rectangular shape which bears upon a flat surface formed on one side of the shaft. The key is not sunk into the shaft but it gives it a fairly good grip. This type is not adapted to heavy work, however, owing to the excessive strains to which the hub is subjected, as the shaft tends to turn.

Nordberg Key.—This is a taper key of circular cross-section. This type of key may be used for attaching hand wheels to their shafts or for other similar light work requiring an inexpensive type of key. The Nordberg key has a taper of 1/16 inch per foot. The center of the key hole is located at the joint line between the shaft and hub. A small hole may be drilled first to prevent the larger drill from crowding over into the cast-iron hub. A general rule for determining the size of the key is to make the large key diameter equal to one-fourth the shaft diameter.

Kennedy Key.—The Kennedy or double key system is used in rolling mills and is adapted to the transmission of heavy loads, especially where the torque is intermittent and the direction of rotation periodically reversed. Each key is so located that a diagonal line passing through two corners of the key approximately intersects the shaft axis. The keys have a taper of $\frac{1}{8}$ inch per foot on the hub side and the sides fit closely between the shaft and hub. The keys are driven in from opposite sides of the hub.

Pipe and Pipe Fittings

Wrought Steel Pipe.— ANSI/ASME B36.10M-1995 covers dimensions of welded and seamless wrought steel pipe, for high or low temperatures or pressures.

The word *pipe* as distinguished from *tube* is used to apply to tubular products of dimensions commonly used for pipelines and piping systems. Pipe dimensions of sizes 12 inches and smaller have outside diameters numerically larger than the corresponding nominal sizes whereas outside diameters of tubes are identical to nominal sizes.

Size: The size of all pipe is identified by the nominal pipe size. The manufacture of pipe in the nominal sizes of ⅛ inch to 12 inches, inclusive, is based on a standardized outside diameter (OD). This OD was originally selected so that pipe with a standard OD and having a wall thickness which was typical of the period would have an inside diameter (ID) approximately equal to the nominal size. Although there is now no such relation between the existing standard thicknesses, ODs and nominal sizes, these nominal sizes and standard ODs continue in use as "standard."

The manufacture of pipe in nominal sizes of 14-inch OD and larger proceeds on the basis of an OD corresponding to the nominal size.

Weight: The nominal weights of steel pipe are calculated values and are tabulated in Table 1. They are based on the following formula:

$$W_{pe} = 10.68(D - t)t$$

where W_{pe} = nominal plain end weight to the nearest 0.01 lb/ft.

D = outside diameter to the nearest 0.001 inch

t = specified wall thickness rounded to the nearest 0.001 inch

Wall thickness: The nominal wall thicknesses are given in Table 1 which also indicates the wall thicknesses in API Standard 5L.

The wall thickness designations "Standard," "Extra-Strong," and "Double Extra-Strong" have been commercially used designations for many years. The Schedule Numbers were subsequently added as a convenient designation for use in ordering pipe. "Standard" and Schedule 40 are identical for nominal pipe sizes up to 10 inches, inclusive. All larger sizes of "Standard" have ⅜-inch wall thickness. "Extra-Strong" and Schedule 80 are identical for nominal pipe sizes up to 8 inch, inclusive. All larger sizes of "Extra-Strong" have ½-inch-wall thickness.

Wall Thickness Selection: When the selection of wall thickness depends primarily on capacity to resist internal pressure under given conditions, the designer shall compute the exact value of wall thickness suitable for conditions for which the pipe is required as prescribed in the "ASME Boiler and Pressure Vessel Code," "ANSI B31 Code for Pressure Piping," or other similar codes, whichever governs the construction. A thickness can then be selected from Table 1 to suit the value computed to fulfill the conditions for which the pipe is desired.

Metric Weights and Mass: Standard SI metric dimensions in millimeters for outside diameters and wall thicknesses may be found by multiplying the inch dimensions by 25.4. Outside diameters converted from those shown in Table 1 should be rounded to the nearest 0.1 mm and wall thicknesses to the nearest 0.01 mm.

The following formula may be used to calculate the SI metric plain end mass in kg/m using the converted metric diameters and thicknesses:

$$W_{pe} = 0.02466(D - t)t$$

where W_{pe} = nominal plain end mass rounded to the nearest 0.01 kg/m.

D = outside diameter to the nearest 0.1 mm for sizes shown in Table 1.

t = specified wall thickness rounded to the nearest 0.01 mm.

Plastics Pipe.— Shortly after World War II, plastics pipe became an acceptable substitute, under certain service conditions, for other piping materials. Now, however, plastics pipe is specified on the basis of its own special capabilities and limitations. The largest volume of application has been for water piping systems.

Besides being light in weight, plastics pipe performs well in resisting deterioration from corrosive or caustic fluids. Even if the fluid borne is harmless, the chemical resistance of plastics pipe offers protection against a harmful exterior environment, such as when buried in a corrosive soil.

Generally, plastics pipe is limited by its temperature and pressure capacities. The higher the operating pressure of the pipe system, the less will be its temperature capability. The reverse is true, also. Since it is formed from organic resins, plastics pipe will burn. For various piping compositions, ignition temperatures vary from 700° to 800°F (370° to 430°C).

The following are accepted methods for joining plastics pipe:

Solvent Welding is usually accomplished by brushing a solvent cement on the end of the length of pipe and into the socket end of a fitting or the flange of the next pipe section. A chemical weld then joins and seals the pipe after connection.

Threading is a procedure not recommended for thin-walled plastics pipe or for specific grades of plastics. During connection of thicker-walled pipe, strap wrenches are used to avoid damaging and weakening the plastics.

Heat Fusion involves the use of heated air and plastics filler rods to weld plastics pipe assemblies. A properly welded joint can have a tensile strength equal to 90 percent that of the pipe material.

Elastomeric Sealing is used with bell-end piping. It is a recommended procedure for large diameter piping and for underground installations. The joints are set quickly and have good pressure capabilities.

The nominal weights of plastics pipe given in this table are based on an empirically chosen material density of 1.00 g/cm^3. The nominal unit weight for a specific plastics pipe formulation can be

www.EngineeringEBooksPdf.com

obtained by multiplying the weight values from the table by the density in g/cm^3 or by the specific gravity of the particular platics composition.

The following are ranges of density factors for various plastics pipe materials: PE, 0.93 to 0.96; PVC, 1.35 to 1.40; CPVC, 1.55; ABS, 1.04 to 1.08; SR, 1.05; PB, 0.91 to 0.92; and PP, 0.91. For meanings of abbreviations see Table 6.

Information supplied by the Plastics Pipe Institute.

Insert Fitting is particularly useful for PE and PB pipe. For joining pipe sections, insert fittings are pushed into the pipe and secured by stainless steel clamps.

Transition Fitting involves specially designed connectors to join plastic pipe with other materials, such as cast iron, steel, copper, clay, and concrete.

Plastic pipe can be specified by means of Schedules 40, 80, and 120, which conform dimensionally to metal pipe, or through a Standard Dimension Ratio (SDR). The SDR is a rounded value obtained by dividing the average outside diameter of the pipe by the wall thickness. Within an individual SDR series of pipe, pressure ratings are uniform, regardless of pipe diameter.

Table 5 provides the weights and dimensions for Schedule 40 and 80 thermoplastic pipe, Table 6 gives properties of plastics pipe, Table 7 gives maximum non-shock operating pressures for several varieties of Schedule 40 and 80 plastics pipe at 73°F, and Table 8 gives correction factors to pressure ratings for elevated temperatures.

Table 6. General Properties and Uses of Plastic Pipe

Plastic Pipe Material	Properties	Common Uses	Operating Temperature[a]		Joining Methods
			With Pressure	Without Pressure	
ABS (Acrylonitrileb-utadiene sty-rene)	Rigid; excellent impact strength at low tempera-tures; maintains rigidity at higher temperatures.	Water, Drain, Waste, Vent, Sewage.	100°F (38°C)	180°F (82°C)	Solvent cement, Thread-ing, Transition fitting.
PE (Polyethylene)	Flexible; excellent impact strength; good perfor-mance at low temperatures.	Water, Gas, Chemical, Irrigation.	100°F (38°C)	180°F (82°C)	Heat fusion, Insert and Transition fitting.
PVC (Polyvinylchlo-ride)	Rigid; fire self-extinguish-ing; high impact and ten-sile strength.	Water, Gas, Sewage, Industrial process, Irri-gation.	100°F (38°C)	180°F (82°C)	Solvent cement, Elasto-meric seal, Mechanical coupling, Transition fit-ting.
CPVC (Chlorinated polyvinyl chlo-ride)	Rigid; fire self-extinguish-ing; high impact and ten-sile strength.	Hot and cold water, Chem-ical.	180°F (82°C) at 100 psig (690kPa) for SDR-11		Solvent cement, Thread-ing, Mechanical cou-pling, Transition fitting.
PB (Polybutylene)	Flexible; good performance at elevated temperatures.	Water, Gas, Irrigation.	180°F (82°C)	200°F (93°C)	Insert fitting, Heat fusion, Transition fitting.
PP (Polypropylene)	Rigid; very light; high chemical resistance, partic-ularly to sulfur-bearing compounds.	Chemical waste and processing.	100°F (38°C)	180°F (82°C)	Mechanical coupling, Heat fusion, Threading.
SR (Styrene rubber plastic)	Rigid; moderate chemical resistance; fair impact strength.	Drainage, Septic fields.	150°F (66°C)	…	Solvent cement, Transition fitting, Elastomeric seal.

[a] The operating temperatures shows are general guide points. For specific operating temperature and pressure data for various grades of the types of plastic pipe given, please consult the pipe manufacturer or the Plastics Pipe Institute.

280	NR	NR	NR	0.18

[a] Recommended for intermittent drainage pressure not exceeding 20 psi.

NR = not recommended.

For more detailed information concerning the properties of a particular plastic pipe formulation, consult the pipe manufacturer or Plastics Pipe Institute, 1825 Connecticut Ave. NW, Washington, D.C. 2009.

www.EngineeringEBooksPdf.com

Pipe and Tube Bending.—In bending a pipe or tube, the outer part of the bend is stretched and the inner section compressed, and as the result of opposite and unequal stresses, the pipe or tube tends to flatten or collapse. To prevent such distortion, the common practice is to support the wall of the pipe or tube in some manner during the bending operation. This support may be in the form of a filling material, or, when a bending machine or fixture is used, an internal mandrel or ball-shaped member may support the inner wall when required.

If a filling material is used, it is melted and poured into the pipe or tube. Many filler materials made up from combinations of bismuth, lead, tin, and cadmium, with melting points around 160 degrees F are commercially available. With this material, tubes having very thin walls have been bent to small radii. The metal filler conforms to the inside of the tube so closely that the tube can be bent just as though it were a solid rod. The filler is removed readily by melting.

This method has been applied to the bending of copper, brass, duralumin, plain steel, and stainless steel tubes with uniform success. Tubes plated with chromium or nickel can often be bent without danger of the plate flaking off. Other filling materials such as resin, tar, lead, and dry sand have also been used.

Pipes are often bent to avoid the use of fittings, thus eliminating joints, providing a smooth unobstructed passage for fluids, and resulting in certain other advantages.

Minimum Radius: The safe minimum radius for a given diameter, material, and method of bending depends upon the thickness of the pipe wall, it being possible, for example, to bend extra heavy pipe to a smaller radius than pipe of standard weight. As a general rule, wrought iron or steel pipe of standard weight may readily be bent to a radius equal to five or six times the nominal pipe diameter. The minimum radius for standard weight pipe should, as a rule, be three and one-half to four times the diameter. It will be understood, however, that the minimum radius may vary considerably, depending upon the method of bending. Extra heavy pipe may be bent to radii varying from two and one-half times the diameter for smaller sizes to three and one-half to four times the diameter for larger sizes.

Rules for Finding Lengths of Bends: In determining the required length of a pipe or tube before bending, the lengths of the straight sections are, of course, added to the lengths required for the curved sections in order to make the proper allowance for bends. The following rules are for finding the lengths of the curved sections.

Length of 90-Degree Bend: To find the length of a 90-degree or right-angle bend, multiply the radius of the bend by 1.57. The radius is measured to the center of the pipe, or to a point midway between the inner and outer walls.

Length of 180-Degree Bend: Multiply the radius of the bend by 3.14.

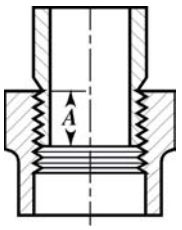
Length of other than 90- or 180-Degree Bend: Multiply the radius of the bend by the included angle, and then multiply the product by the constant $\pi/180 = 0.01745$. The result is the length of the curved section.

Threading Pipe.—Clean, smooth pipe threads are essential to a good joint and depend largely upon the rake or lip angle and lead of the chasers, and the clearance, chip space and number of chasers in the die-head. The lip angle should vary from 15 to 25 degrees, depending upon the style and condition of the chasers and chaser holders. The chip space in front of the chasers should be large enough to allow room for accumulation of chips and at the same time provide means of lubricating the chasers. This is an important point, as insufficient chip space will cause the chips to clog and tear the threads. The lead of the chaser is the angle which is machined or ground on the leading or front side, to enable the die to start readily on the pipe, and also to distribute the work of cutting over a number of threads. To secure a good thread, the lead should cover the first three threads. As the heaviest cutting is done by this beveled part, it should have a slightly greater clearance angle than the rest of the threads on the chaser. When re-grinding chasers which have become

www.EngineeringEBooksPdf.com

dull on the lead, care should be taken to give each chaser the same length of lead, as otherwise the work will be unevenly distributed.

Length of Thread on Pipe Required to Make a Tight Joint (Crane Co.)



Size of Pipe, Inches	Dimension *A*, Inches	Size of Pipe, Inches	Dimension *A*, Inches	Size of Pipe, Inches	Dimension *A*, Inches
1/8	1/4	1 1/2	11/16	5	1 1/4
1/4	3/8	2	3/4	6	1 5/16
3/8	3/8	2 1/2	15/16	7	1 3/8
1/2	1/2	3	1	8	1 7/16
3/4	9/16	3 1/2	1 1/16	9	1 1/2
1	11/16	4	1 1/8	10	1 5/8
1 1/4	11/16	4 1/2	1 3/16	12	1 3/4

Dimensions do not allow for variation in tapping or threading.

Definitions of Pipe Fittings.—The following definitions for various pipe fittings are given by the National Tube Co.:

Armstrong Joint: A two-bolt, flanged or lugged connection for high pressures. The ends of the pipes are peculiarly formed to properly hold a gutta-percha ring. It was originally made for cast-iron pipe. The two-bolt feature has much to corn-mend it. There are various substitutes for this joint, many of which employ rubber in place of gutta-percha; others use more bolts in order to reduce the cost.

Bell and Spigot Joint: a) The usual term for the joint in cast-iron pipe. Each piece is made with an enlarged diameter or bell at one end into which the plain or spigot end of another piece is inserted when laying. The joint is then made tight by cement, oakum, lead, rubber or other suitable substance, which is driven in or calked into the bell and around the spigot. When a similar joint is made in wrought pipe by means of a cast bell (or hub), it is at times called hub and spigot joint (poor usage). Matheson joint is the name applied to a similar joint in wrought pipe which has the bell formed from the pipe.

b) Applied to fittings or valves, means that one end of the run is a "bell," and the other end is a "spigot," similar to those used on regular cast-iron pipe.

Bonnet: a) A cover used to guide and enclose the tail end of a valve spindle.

b) A cap over the end of a pipe (poor usage).

Branch: The outlet or inlet of a fitting not in line with the run, but which may make any angle.

Branch Ell: a) Used to designate an elbow having a back outlet in line with one of the outlets of the "run." It is also called a heel outlet elbow.

b) Incorrectly used to designate side outlet or back outlet elbow.

Branch Pipe: A very general term used to signify a pipe either cast or wrought, that is equipped with one or more branches. Such pipes are used so frequently that they have acquired common names such as tees, crosses, side or back outlet elbows, manifolds, double-branch elbows, etc. The term branch pipe is generally restricted to such as do not conform to usual dimensions.

Branch Tee or Header: A tee having many side branches. (See *Manifold*.)

Bull Head Tee: A tee the branch of which is larger than the run.

Bushing: A pipe fitting for the purpose of connecting a pipe with a fitting of larger size, being a hollow plug with internal and external threads to suit the different diameters.

Card Weight Pipe: A term used to designate standard or full weight pipe, which is the Briggs' standard thickness of pipe.

Close Nipple: One the length of which is about twice the length of a standard pipe thread and is without any shoulder.

Coupling: A threaded sleeve used to connect two pipes. Commercial couplings are threaded inside to suit the exterior thread of the pipe. The term coupling is occasionally used to mean any jointing device and may be applied to either straight or reducing sizes.

www.EngineeringEBooksPdf.com

Cross: A pipe fitting with four branches arranged in pairs, each pair on one axis, and the axes at right angles. When the outlets are otherwise arranged the fittings are branch pipes or specials.

Cross-over: A small fitting with a double offset, or shaped like the letter U with the ends turned out. It is only made in small sizes and used to pass the flow of one pipe past another when the pipes are in the same plane.

Cross-over Tee: A fitting made along lines similar to the cross-over, but having at one end two openings in a tee-head the plane of which is at right angles to the plane of the cross-over bend.

Cross Valve: a) A valve fitted on a transverse pipe so as to open communication at will between two parallel lines of piping. Much used in connection with oil and water pumping arrangements, especially on ship board.

b) Usually considered as an angle valve with a back outlet in the same plane as the other two openings.

Crotch: A fitting that has the general shape of the letter Y. Caution should be exercised not to confuse the crotch and wye.

Double-branch Elbow: A fitting that, in a manner, looks like a tee, or as if two elbows had been shaved and then placed together, forming a shape something like the letter Y or a crotch.

Double Sweep Tee: A tee made with easy curves between body and branch, i.e., the center of the curve between run and branch lies outside the body.

Drop Elbow: A small sized ell that is frequently used where gas is put into a building. These fittings have wings cast on each side. The wings have small countersunk holes so that they may be fastened by wood screws to a ceiling or wall or framing timbers.

Drop Tee: One having the same peculiar wings as the drop elbow.

Dry Joint: One made without gasket or packing or smear of any kind, as a ground joint.

Elbow (ELL): A fitting that makes an angle between adjacent pipes. The angle is always 90 degrees, unless another angle is stated. (See *Branch Ell*, *Service Ell*, and *Union Ell*.)

Extra Heavy: When applied to pipe, means pipe thicker than standard pipe; when applied to valves and fittings, indicates goods suitable for a working pressure of 250 pounds per square inch.

Header: A large pipe into which one set of boilers is connected by suitable nozzles or tees, or similar large pipes from which a number of smaller ones lead to consuming points. Headers are often used for other purposes-for heaters or in refrigeration work. Headers are essentially branch pipes with many outlets, which are usually parallel. Largely used for tubes of water-tube boilers.

Hydrostatic Joint: Used in large water mains, in which sheet lead is forced tightly into the bell of a pipe by means of the hydrostatic pressure of a liquid.

Kewanee Union: A patented pipe union having one pipe end of brass and the other of malleable iron, with a ring or nut of malleable iron, in which the arrangement and finish of the several parts is such as to provide a non-corrosive ball-and-socket joint at the junction of the pipe ends, and a non-corrosive connection between the ring and brass pipe end.

Lead Joint: a) Generally used to signify the connection between pipes which is made by pouring molten lead into the annular space between a bell and spigot, and then making the lead tight by calking.

b) Rarely used to mean the joint made by pressing the lead between adjacent pieces, as when a lead gasket is used between flanges.

Lead Wool: A material used in place of molten lead for making pipe joints. It is lead fiber, about as coarse as fine excelsior, and when made in a strand, it can be calked into the joints, making them very solid.

Line Pipe: Special brand of pipe that employs recessed and taper thread couplings, and usually greater length of thread than Briggs' standard. The pipe is also subjected to higher test.

www.EngineeringEBooksPdf.com

Lip Union: a) A special form of union characterized by the lip that prevents the gasket from being squeezed into the pipe so as to obstruct the flow.

b) A ring union, unless flange is specified.

Manifold: a) A fitting with numerous branches used to convey fluids between a large pipe and several smaller pipes. (See *Branch Tee or Header*.)

b) A header for a coil.

Matheson Joint: A wrought pipe joint made by enlarging. one end of the pipe to form a suitable lead recess, similar to the bell end of a cast-iron pipe, and which receives the male or spigot end of the next length. Practically the same style of a joint as used for cast-iron pipe.

Medium Pressure: When applied to valves and fittings, means suitable for a working pressure of from 125 to 175 pounds per square inch.

Needle Valve: A valve provided with a long tapering point in place of the ordinary valve disk. The tapering point permits fine graduation of the opening. At times called a needle point valve.

Nipple: A tubular pipe fitting usually threaded on both ends and under 12 inches in length. Pipe over 12 inches long is regarded as cut pipe. (See *Close Nipple*, *Short Nipple*, *Shoulder Nipple*, and *Space Nipple*.)

Reducer: a) A fitting having a larger size at one end than at the other. Some have tried to establish the term "increaser" — thinking of direction of flow —but this has been due to a misunderstanding of the trade custom of always giving the largest size of run of a fitting first; hence, all fittings having more than one size are reducers. They are always threaded inside, unless specified flanged or for some special joint.

b) Threaded type, made with abrupt reduction.

c) Flanged pattern with taper body.

d) Flanged eccentric pattern with taper body, but flanges at 90 degrees to one side of body.

e) Misapplied at times, to a reducing coupling.

Run: a) A length of pipe that is made of more than one piece of pipe.

b) The portion of any fitting having its ends "in line" or nearly so, in contradistinction to the branch or side opening, as of a tee. The two main openings of an ell also indicate its run, and when there is a third opening on an eli, the fitting is a "side outlet" or "back outlet" elbow, except that when all three openings are in one plane and the back outlet is in line with one of the run openings, the fitting is a "heel outlet elbow" or a "single sweep tee" or sometimes a "branch tee."

Rust Joint: Employed to secure rigid connection. The joint is made by packing an intervening space tightly with a stiff paste which oxidizes the iron, the whole rusting together and hardening into a solid mass. It generally cannot be separated except by destroying some of the pieces. One recipe is 80 pounds cast-iron borings or filings, 1 pound sal-ammoniac, 2 pounds flowers of sulphur, mixed to a paste with water.

Service Ell: An elbow having an outside thread on one end. Also known as street ell.

Service Pipe: A pipe connecting mains with a dwelling.

Service Tee: A tee having inside thread on one end and on branch, but outside thread on other end of run. Also known as street tee.

Short Nipple: One whose length is a little greater than that of two threaded lengths or somewhat longer than a close nipple. It always has some unthreaded portion between the two threads.

Shoulder Nipple: A nipple of any length, which has a portion of pipe between two pipe threads. As generally used, however, it is a nipple about halfway between the length of a close nipple and a short nipple.

Space Nipple: A nipple with a portion of pipe or shoulder between the two threads. It may be of any length long enough to allow a shoulder.

Standard Pressure: A term applied to valves and fittings suitable for a working steam pressure of 125 pounds per square inch.

www.EngineeringEBooksPdf.com

Tee: A fitting, either cast or wrought, that has one side outlet at right angles to the run. A single outlet branch pipe. (See *Branch Tee or Header*, *Bull Head Tee*, *Cross-over Tee*, *Double Sweep Tee*, *Drop Tee*, *Service Tee*, and *Union Tee*.)

Union: The usual trade term for a device used to connect pipes. It commonly consists of three pieces which are, first, the thread end fitted with exterior and interior threads; second, the bottom end fitted with interior threads and a small exterior shoulder; and third, the ring which has an inside flange at one end while the other end has an inside thread like that on the exterior of the thread end. A gasket is placed between the thread and bottom ends, which are drawn together by the ring. Unions are very extensively used, because they permit of connections with little disturbance of the pipe positions.

Union Ell: An ell with a male or female union at one end.

Union Joint: A pipe coupling, usually threaded, which permits disconnection without disturbing other sections.

Union Tee: A tee with male or female union at connection on one end of run.

Wiped Joint: A lead joint in which the molten solder is poured upon the desired place, after scraping and fitting the parts together, and the joint is wiped up by hand with a moleskin or cloth pad while the metal is in a plastic condition.

Wye (Y): A fitting either cast or wrought that has one side outlet at any angle other than 90 degrees. The angle is usually 45 degrees, unless another angle is specified. The fitting is usually indicated by the letter Y.

Clutches

A clutch is a form of coupling which is designed to connect or disconnect a driving or driven member for starting or stopping the driven part. A clutch consists principally of two main sections which are engaged or disengaged either at will by a hand-operated controlling device, or automatically by the action of some power-driven mechanical apparatus, such as a cam connected by suitable means with the shifting clutch member. There are several distinct types of clutches which are made in a great variety of designs. The common types of clutches may be divided into two general classes; namely, (1) those having teeth which interlock, or positive clutches, and (2) those which transmit motion from the driving to the driven part of the clutch by frictional contact.

A third type, the induction clutch, similar in its operation to an induction motor, transmits power without contact between its driving and driven members.

Friction Clutches.—A friction clutch is used for transmitting power from one machine member to another by means of frictional contact between members attached to the driving and driven machine parts. These clutches are made in many different designs, there being, however, four types that predominate; the conical clutch, the radial-expanding friction clutch, the contracting-band clutch, and the friction disk clutch. Friction clutches are used when it is desired to have a smooth and gradual engagement and disengagement of the driving and driven members.

When motion is transmitted from the driving to the driven parts of a clutch simply by frictional contact, the load may be started gradually and without shock, such as often occurs when a positive clutch is engaged. The different types of friction clutches vary in regard to the form of the friction surfaces and with respect to the kinds of material used to obtain sufficient frictional resistance. The frictional surfaces may be either conical or cylindrical, or in the form of one or more flat rings or disks.

Conical Clutches: A conical clutch is so designed that motion is transmitted by the frictional resistance of engaging conical surfaces. The effectiveness of any friction clutch as a transmitter of power varies with the coefficient or degree of friction between the engaged surfaces. The frictional surfaces may both be of metal, but, in many cases, one member has a metal surface and the other is partially or entirely covered with some material such as leather or an asbestos fabric. The cast iron and leather combination is common, and pieces of cork inserted in holes drilled in one member is another common method of increasing

www.EngineeringEBooksPdf.com

frictional resistance. It is common practice to maintain the driving and driven members of friction clutches in engagement by means of springs which are compressed in order to release the clutch. The angle of the conical surfaces is usually about 12 or 13 degrees. The conical type of friction clutch is simple in construction but rather bulky or large when compared with other types of equal capacity as transmitters of power.

Cone Clutch: A friction clutch in which one friction surface is in the form of a frustum of a cone and which, for engagement, is forced into the other member which is made to fit it on the inside. One friction surface may be covered with leather. If the angle of the conical surface of the cone type of clutch is too small, it may be difficult to release the clutch on account of the wedging effect, whereas, if the angle is too large, excessive pressure will be required to prevent slipping. The minimum angle for a leather-faced cone is about 8 or 9 degrees and the maximum angle about 13 degrees. An angle of 12½ degrees appears to be the most common and is generally considered good practice. These angles are given with relation to the clutch axis and are one-half the included angle.

Disk Clutch: A common design of disk clutch consists of a set of driving disks and a set of driven disks located alternately, so that each driving disk is between two driven disks. The driving disks may have key slots on their outer circumferences which are engaged by a key on the inner side of a driving drum, and the driven disks may be provided with lugs or key slots on the inner circumference for connection with the driven member.

Both the driving and driven disks of many clutches are metallic and run in oil. Steel disks about 1/16 inch thick are often used. One set of disks may be of bronze, or possibly of sheet copper. One multiple-disk clutch which has been extensively used has alternate disks of steel and phosphor-bronze. These disks have V-shaped grooves instead of being flat, frictional contact being between the angular surfaces. In dry-plate clutches, one set of plates may be faced on both sides with asbestos fabric, or cork inserts may be used.

Expanding Type of Friction Clutch: The radially expanding type of clutch is a form that has been widely used, the details of the design being varied more or less. A typical design consists of an outer casing in which there are two expanders or segment-shaped pieces connected by right- and left-hand screws, respectively. These screws are attached to levers, which, in turn, are connected to the sliding sleeve, by links, thus forming toggles between the sleeve and the screws. The two expanders and the toggle mechanism are caused to revolve with the shaft by a central driving hub. The clutch is operated by shifting the sliding sleeve and toggles; this movement turns the screws having right- and left-hand threads far enough to either expand the inner members tightly against the outer casing or to withdraw them from frictional contact. The expanders may be lined with maple grips, to increase the frictional resistance.

Hele-Shaw Clutch: This is a clutch devised by Prof. HeleShaw. Its principal feature is that power is transmitted through the friction between grooved disks. A number of these disks are placed in the clutch, each disk having a V-groove which fits into the V-groove of the next disk. Every other disk is connected to an outside drum, and the alternating disks, to the shaft to which power is to be transmitted. It has been found that V-shaped disks transmit considerably more power and permit of a more even “pick-up” than clutches with flat disks.

Internal Expanding Clutch: This is a friction clutch provided with shoes which are forced outward against an enclosing drum by the action of levers connecting with a collar free to slide along the shaft. The engaging shoes are usually lined with wood.

Magnetic Clutches: Magnetic clutches may be obtained having horsepower ratings varying from one to two horsepower up to several hundred horsepower. Such clutches are adapted particularly for high-speed drives, for heavy duty, and for use when there is difficulty in starting a heavy load with a motor. Magnetic clutches are also useful when machinery must be stopped quickly, a brake being used in such cases in combination with the clutch. One design of magnetic clutch has the field or driving member and the armature or driven member each carried by a flexible spring-steel plate so that when current passes

www.EngineeringEBooksPdf.com

through the field winding, the armature is attracted to it and friction surfaces come into engagement. The magnetizing winding of the field receives current through two collector rings and graphite brushes, and direct current is used. The clutch driving capacity depends upon the friction surfaces which are held together by the magnetic attraction.

Ring and Disk Clutches: Many clutches of the friction type transmit motion from the driving to the driven side through the frictional resistance of rings, plates, or disks which are pressed together, the resistance being between the flat surfaces of the rings or disks which are thus held in contact. Some clutches of this general type have a few comparatively heavy rings, whereas others are equipped with a larger number of thin rings. By using quite a number of disks or rings instead of one or two, the diameter of the clutch may be reduced without sacrificing the contact area or the amount of frictional surface. Various combinations of materials are used for the disks of multiple-disk clutches. One set, for example, may be of soft steel and the other of phosphor-bronze, and in other types one set of disks is faced with some special friction material such as asbestos wire fabric, as in the case of dry plate clutches, the disks of which are not lubricated like those of a clutch having, for example, the steel and phosphor-bronze combination.

Positive Clutch.—This is a clutch for transmitting power between two machine members, the driving and driven members of which are connected by the engagement of interlocking teeth or projecting lugs, so that there is no slippage, the power being transmitted in a positive manner. This type of clutch is employed when a sudden starting action is not objectionable, and when the inertia of the driven parts is relatively small. The teeth of positive clutches are made in a number of different shapes, according to the service for which they are required.

Spiral-Jaw Clutch: A spiral-jaw clutch is a positive clutch in which the tops of the tooth surfaces are helicoidal, the front of the tooth being flat and. in the plane of the axis of the clutch. Clutches of this type can only transmit motion in one direction, and are, therefore, known as right- and left-hand.

Square-Jaw Clutch: This is a positive clutch provided with teeth having perpendicular or square sides, so that, when engaged, the clutch will drive in either direction. Clutches of this type cannot he engaged and disengaged readily unless stationary or revolving slowly.

Clutches that Automatically Disengage.—The clutches used on power presses and some other kinds of machines are designed to automatically disengage after making one or more revolutions. The clutch connects the fly-wheel or driving gear of the press with the driven shaft, whenever it is tripped, by pressing down a foot-treadle. As long as this treadle is held down, the clutch remains in engagement and the press continues to run; if the treadle is released, the clutch is disengaged when the ram or slide of the press is approximately at the top of its stroke. The downward movement of the treadle releases a pin, key, or some other form of locking device which quickly engages the driving member; when the treadle is released, the locking device encounters some form of trip or cam surface which withdraws it and stops the press. There are many designs of clutches of this general type.

www.EngineeringEBooksPdf.com

Motion Control

The most important factor in the manufacture of accurately machined components is the control of motion, whatever power source is used. For all practical purposes, motion control is accomplished by electrical or electronic circuits, energizing or deenergizing actuators such as electric motors or solenoid valves connected to hydraulic or pneumatic cylinders or motors. The accuracy with which a machine tool slide, for example, may be brought to a required position, time after time, controls the dimensions of the part being machined. This accuracy is governed by the design of the motion control system in use.

There is a large variety of control systems, with power outputs from milliwatts to megawatts, and they are used for many purposes besides motion control. Such a system may control a mechanical positioning unit, which may be linear or rotary, its velocity, acceleration, or combinations of these motion parameters. A control system may also be used to set voltage, tension, and other manufacturing process variables and to actuate various types of solenoid-operated valves. The main factors governing design of control systems are whether they are to be open- or closed-loop; what kinds and amounts of power are available; and the function requirements.

Factors governing selection of control systems are listed in Table 1.

Table 1. Control System Application Factors

Type of System	Nature of required control motion, i.e., position, velocity, acceleration
Accuracy	Controlled output versus input
Mechanical Load	Viscous friction, coulomb friction, starting friction, load inertia
Impact Loads	Hitting mechanical stops and load disturbances
Ratings	Torque or force, and speed
Torque	Peak instantaneous torque
Duty Cycle	Load response, torque level, and duration and effect on thermal response
Ambient Temperature	Relation to duty cycle and internal temperature rise, and to the effect of temperature on the sensor
Speed of Response	Time to reach commanded condition. Usually defined by a response to a stepped command
Frequency Response	Output to input ratio versus frequency, for varying frequency and specified constant input amplitude. Usually expressed in decibels
No-Load Speed	Frequently applies to maximum kinetic energy and to impact on stops; avoiding overspeeding
Backdriving	With power off, can the load drive the motor? Is a fail-safe brake required? Can the load backdrive with power on without damage to the control electronics? (Electric motor acting as a generator)
Power Source	Range of voltage and frequency within which the system must work. Effect of line transients
Environmental Conditions	Range of nonoperating and operating conditions, reliability and serviceability, scheduled maintenance

Open-Loop Systems.—The term open-loop typically describes use of a rheostat or variable resistance to vary the input voltage and thereby adjust the speed of an electric motor, a low-accuracy control method because there is no output sensor to measure the performance. However, use of stepper motors (see Table 2, and page 3414) in open-loop systems can make them very accurate. Shafts of stepper motors are turned through a fixed angle for every electrical pulse transmitted to them. The maximum pulse rate can be high, and the shaft can be coupled with step-down gear drives to form inexpensive, precise drive units with wide speed ranges. Although average speed with stepper motors is exact, speed modulation can occur at low pulse rates and drives can incur serious resonance problems.

www.EngineeringEBooksPdf.com

Table 2. Control Motor Types

AC Motors	Induction motors, simplest, lowest cost, most rugged, can work directly off the ac line or through an inexpensive, efficient, and compact thyristor controller. Useful in fan and other drives where power increases rapidly with speed as well as in simple speed regulation. Ac motors are larger than comparable permanent-magnet motors
Two-Phase Induction Motors	Often used as control motors in small electromechanical control systems. Power outputs range from a few milliwatts to tens of watts
Split-Field Series Motors	Work on both ac and dc. Feature high starting torque, low cost, uniform power output over a wide speed range, and are easily reversed with a single-pole three-position switch. Very easy to use with electric limit switches for controlling angle of travel
Permanent-Magnet Motors	Operate on dc, with high power output and high efficiency. The most powerful units use rare-earth magnets and are more expensive than conventional types. Lower-cost ferrite magnets are much less expensive and require higher gear-reduction ratios, but at their higher rated speeds are very efficient
Brushless DC Motors	Use electrical commutation and may be applied as simple drive motors or as four-quadrant control motors. The absence of brushes for commutation ensures high reliability and low electromagnetic interference
Stepper Motors	Index through a fixed angle for each input pulse so that speed is in exact proportion to pulse rate and the travel angle increases uniformly with the number of pulses. Proper application in systems with backlash and load inertia requires special care
Wound-Field DC Motors	For subfractional to integral horsepower applications where size is not significant. Cost is moderate because permanent magnets are not required. Depending on the windings, output characteristics can be adjusted for specific applications

Open-loop systems are only as accurate as the input versus output requirement can be calibrated, including the effects of changes in line voltage, temperature, and other operating conditions.

Closed-Loop Systems.—Table 3 shows some parameters and characteristics of closed-loop systems, and a simple example of such a system is shown below. A command may be input by a human operator, it may be derived from another piece of system equipment, or it may be generated by a computer. Generally, the command is in the form of an electrical signal. The system response is converted by the output sensor to a compatible, scaled electrical signal that may be compared with the input command, the difference constituting an error signal. It is usually required that the error be small, so it is amplified and applied to an appropriate driving unit. The driver may take many forms, but for motion control it is usually a motor.

The amplified error voltage drives the motor to correct the error. If the input command is constant, the system is a closed-loop regulator.

Closed-loop systems use feedback sensors that measure system output and give instructions to the power drive components, based on the measured values. A typical closed-loop speed control, for instance, uses a tachometer as a feedback sensor and will correct automatically for differences between the tachometer output and the commanded speed. All motion control systems require careful design to achieve good practical performance. Closed-loop systems generally cost more than open-loop systems because of the extra cost of the tachometer or transducer used for output measurement. Faster response components also increase cost.

www.EngineeringEBooksPdf.com

Table 3. Closed-Loop System Parameters and Characteristics

Step Response	The response of the system to a step change in the input command. The response to a large step, which can saturate the system amplifier, is different from the response to a small nonsaturating step. Initial overshoots may not be permissible in some types of equipment
Frequency Response	System response to a specified small-amplitude sinusoidal command where frequency is varied over the range of interest. The response is in decibels (dB), where dB = 20 $\log_{10}$(output/input). This characteristic determines whether the system is responsive enough to meet requirements
Bandwidth	The effective range of input frequencies within which the control system responds well. The bandwidth is often described by the point where the frequency response is down by three decibels. Bandwidth is usually defined in Hz (cycles/sec) or $\omega = 2\pi \times$ Hz (radians/sec)
Loading	The torque required to drive the load and the load inertia. The amplifier must supply enough power to meet acceleration as well as output power requirements. If the load is nonlinear, its effect on error must be within specifications. Behavior may vary considerably, depending on whether the load aids or opposes motor torque, as in a hoist
Output Stiffness	A measure of the system's response to load disturbances. Dynamic stiffness measures the system's response to a rapidly varying load
Resonant Peaks	Can show up in frequency-response testing as sharp (undamped) resonances. These resonances cannot be tolerated in the normal frequency range of the control system because they can lead to oscillation and vibration
No load, or maximum speed and maximum torque	Can be controlled by voltage or current limiting in the electronic amplifier. A slip clutch can also be used for torque limiting, particularly to avoid impact damage

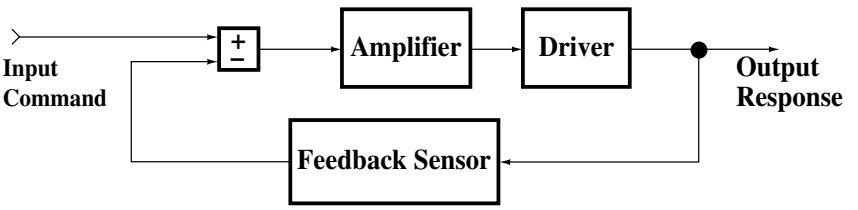


Fig. 1. General Arrangement of a Closed-Loop Control System

Accuracy of closed-loop systems is directly related to the accuracy of the sensor, so that choosing between open-loop and closed-loop controls may mean choosing between low price and consistent, accurate repeatability. In the closed-loop arrangement in Fig. 1, the sensor output is compared with the input command and the difference is amplified and applied to the motor to produce a correction. When the amplifier gain is high (the difference is greatly enlarged), even a small error will generate a correction. However, a high gain can lead to an unstable system due to inherent delays between the electrical inputs and outputs, especially with the motor.

Response accuracy depends not only on the precision of the feedback sensor and the gain of the amplifier, but also on the rate at which the command signal changes. The ability of the control system to follow rapidly changing inputs is naturally limited by the maximum motor speed and acceleration.

Amplified corrections cannot be applied to the motor instantaneously, and the motor does not respond immediately. Overshoots and oscillations can occur and the system must be adjusted or tuned to obtain acceptable performance. This adjustment is called damping

www.EngineeringEBooksPdf.com

the system response. Table 4 lists a variety of methods of damping, some of which require specialized knowledge.

Table 4. Means of Damping System Response

Network Damping	Included in the electrical portion of the closed loop. The networks adjust amplitude and phase to minimize control system feedback oscillations. Notch networks are used to reduce gain at specific frequencies to avoid mechanical resonance oscillations
Tachometer Damping	Feedback proportional to output velocity is added to the error signal for system stabilization
Magnetic Damping	Viscous or inertial dampers on the motor rear shaft extension for closed-loop stabilization. Similar dampers use silicone fluid instead of magnetic means to provide damping
Nonlinear Damping	Used for special characteristics. Inverse error damping provides low damping for large errors, permitting fast slewing toward zero and very stable operation at zero. Other nonlinearities meet specific needs, for example, coulomb friction damping works well in canceling backlash oscillations
Damping Algorithms	With information on output position or velocity, or both, sampled data may be used with appropriate algorithms to set motor voltage for an optimum system response

The best damping methods permit high error amplification and accuracy, combined with the desired degree of stability. Whatever form the output takes, it is converted by the output sensor to an electrical signal of compatible form that can be compared with the input command. The error signal thus generated is amplified before being applied to the driving unit.

Drive Power.— Power for the control system often depends on what is available and may vary from single- and three-phase ac 60 or 400 Hz, through dc and other types. Portable or mobile equipment is usually battery-powered dc or an engine-driven electrical generator. Hydraulic and pneumatic power may also be available. Cost is often the deciding factor in the choice.

Table 5. Special Features of Controllers

Linear or Pulse-Width Modulated	Linear is simpler, PWM is more complex and can generate electromagnetic interference, but is more efficient
Current Limiting	Sets limits to maximum line or motor current. Limits the torque output of permanent magnet motors. Can reduce starting transients and current surges
Voltage Limiting	Sets limits to maximum motor speed. Permits more uniform motor performance over a wide range of line voltages
Energy Absorption	Ability of the controller to absorb energy from a dc motor drive, back-driven by the load
EMI Filtering	Especially important when high electrical gain is required, as in thermocouple circuits, for example
Isolation	Of input and output, sometimes using optoisolators, or transformers, when input and output circuits require a high degree of isolation

Control Function.— The function of the control is usually set by the designer of the equipment and needs careful definition because it is the basis for the overall design. For instance, in positioning a machine tool table, such aspects as speed of movement and permissible variations in speed, accuracy of positioning, repeatability, and overshoot are among dozens of factors that must be considered. Some special features of controllers are listed in Table 5. Complex electromechanical systems require more knowledge of design and debugging than are needed for strictly mechanical systems.

www.EngineeringEBooksPdf.com

Electromechanical Control Systems.—Wiring is the simplest way to connect components, so electromechanical controls are more versatile than pure hydraulic or pneumatic controls. The key to this versatility is often in the controller, the fundamental characteristic of which is its power output. The power output must be compatible with motor and load requirements. Changes to computer chips or software can usually change system performance to suit the application.

When driving a dc motor, for instance, the controller must supply sufficient power to match load requirements as well as motor operating losses, at minimum line voltage and maximum ambient temperature. The system's wiring must not be greatly sensitive to transient or steady-state electrical interference, and power lines must be separated from control signal lines, or appropriately shielded and isolated to avoid cross-coupling. Main lines to the controller must often include electrical interference filters so that the control system does not affect the power source, which may influence other equipment connected to the same source. For instance, an abruptly applied step command can be smoothed out so that heavy motor inrush currents are avoided. The penalty is a corresponding delay in response.

Use of current limiting units in a controller will not only set limits to line currents, but will also limit motor torque. Electronic torque limiting can frequently avoid the need for mechanical torque limiting. An example of the latter is using a slip clutch to avoid damage due to overtravel, the impact of which usually includes the kinetic energy of the moving machine elements. In many geared systems, most of the kinetic energy is in the motor. Voltage limiting is less useful than current limiting but may be needed to isolate the motor from voltage transients on the power line, to prevent overspeeding, as well as to protect electronic components.

Mechanical Stiffness.—When output motion must respond to a rapidly changing input command, the control system must have a wide bandwidth. Where the load mass (in linear motion systems) or the polar moment of inertia (in rotary systems) is high, there is a possibility of resonant oscillations. For the most stable and reliable systems, with a defined load, a high system mechanical stiffness is preferred. To attain this stiffness requires strengthening shafts, preloading bearings, and minimizing free play or backlash. In the best-performing systems, motor and load are coupled without intervening compliant members. Even tightly bolted couplings can introduce compliant oscillations resulting from extremely minute slippages caused by the load motions.

Backlash is a factor in the effective compliance of any coupling but has little effect on the resonant frequency because little energy is exchanged as the load is moved through the backlash region. However, even in the absence of significant torsional resonance, a high-gain control system can “buzz” in the backlash region. Friction is often sufficient to eliminate this small-amplitude, high-frequency component.

The difficulty with direct-drive control systems lies in matching motor to load. Most electric motors deliver rated power at higher speeds than are required by the driven load, so that load power must be delivered by the direct-drive motor operating at a slow and relatively inefficient speed. Shaft power at low speed involves a correspondingly high torque, which requires a large motor and a high-power controller. Motor copper loss (heating) is high in delivering the high motor torque. However, direct-drive motors provide maximum load velocity and acceleration, and can position massive loads within seconds of arc (rotational) or tenths of thousandths of an inch (linear) under dynamic conditions.

Where performance requirements are moderate, the required load torque can be traded off against speed by using a speed-changing transmission, typically, a gear train. The transmission effectively matches the best operating region of the motor to the required operating region of the load, and both motor and controller can be much smaller than would be needed for a comparable direct drive.

Torsional Vibration.—Control system instabilities can result from insufficient stiffness between the motor and the inertia of the driven load. The behavior of such a system is sim-

www.EngineeringEBooksPdf.com

ilar to that of a torsional pendulum, easily excited by commanded motions of the control system. If frictional losses are moderate to low, sustained oscillations will occur. In spite of the complex dynamics of the closed-loop system, the resonant frequency, as for a torsional pendulum, is given to a high degree of accuracy by the formula:

$$f_n = \frac{1}{2\pi} \times \sqrt{\frac{K}{J_L}}$$

where f_n is in hertz, K is torsional stiffness in in.-lb/rad, and J_L is load inertia in in.-lb-sec^2/rad. If this resonant frequency falls within the bandwidth of the control system, self-sustained oscillations are likely to occur. These oscillations are often overlooked by control systems analysts because they do not appear in simple control systems, and they are very difficult to correct.

Friction inherently reduces the oscillation by dissipating the energy in the system inertia. If there is backlash between motor and load, coulomb friction (opposing motion but independent of speed) is especially effective in damping out the oscillation. However, the required friction for satisfactory damping can be excessive, introducing positioning error and adding to motor (and controller) power requirements. Friction also varies with operating conditions and time.

The most common method of eliminating torsional oscillation is to introduce a filter in the error channel of the control system to shape the gain characteristic as a function of frequency. If the torsional resonance is within the required system bandwidth, little can be done except stiffening the mechanical system and increasing the resonant frequency. If the filter reduces the gain within the required bandwidth, it will reduce performance. This method will work only if the natural resonance is above the minimum required performance bandwidth.

The simplest shaping network is the notch network (Table 4, network damping), which, in effect, is a band-rejection filter that sharply reduces gain at the notch frequency. By locating the notch frequency so as to balance out the torsional resonance peak, the oscillation can be eliminated. Where there are several modes of oscillation, several filter networks can be connected in series.

Electric Motors.—Electric motors for control systems must suit the application. Motors used in open-loop systems (excluding stepper motors) need not respond quickly to input command changes. Where the command is set by a human, response times of hundreds of milliseconds to several seconds may be acceptable. Slow response does not lead to the instabilities that time delays can introduce into closed-loop systems.

Closed-loop systems need motors with fast response, of which the best are permanent-magnet dc units, used where wide bandwidth, efficient operation, and high power output are required. Table 2 lists some types of control motors and their characteristics. An important feature of high-performance, permanent-magnet motors using high-energy, rare-earth magnets is that their maximum torque output capacity can be 10 to 20 or more times higher than their rated torque. In intermittent or low-duty-cycle applications, very high torque loads can be driven by a given motor. However, when rare-earth magnets (samarium cobalt or neodymium) are not used, peak torque capability may be limited by the possibility of demagnetization. Rare-earth magnets are relatively expensive, so it is important to verify peak torque capabilities for lower-cost motors that may use weaker Alnico or ferrite magnets.

Duty-cycle calculations are an aspect of thermal analysis that are well understood and are not covered here. Motor manufacturers usually supply information on thermal characteristics including thermal time constants and temperature rise per watt of internal power dissipation.

www.EngineeringEBooksPdf.com

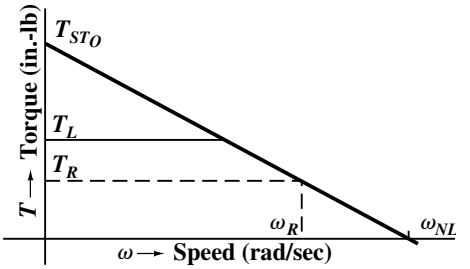

Fig. 2. Idealized Control Motor Characteristics for a Consistent Set of Units

Characteristics of permanent-magnet motors are defined with fair accuracy by relatively few parameters. The most important characteristics are: D_M motor damping in lb-in.-sec/rad; J_M motor inertia in lb-in.-sec^2/rad; and R winding resistance in ohms. Fig. 1 shows other control motor characteristics, T_{STo} stall torque with no current limiting; T_L maximum torque with current limiting; ω_{NL} no-load speed; ω_R rated speed. Other derived motor parameters include V rated voltage in volts; $I_{STo} = V/R$ current in amperes at stall with no current limiting; I_L ampere limit, adjusted in amplifier; I_R rated current; $K_T = T_{STo}/I_{STo}$ torque constant in in.-lb/ampere; $K_E = V/\omega_{NL}$ voltage constant in volt/rad/sec; $K_M = K_T/\sqrt{R}$, torque per square root of winding resistance; $D_M = T_{STo}/\omega_{NL}$ motor damping in in.-lb/rad/sec; and $T_M = J_M/D_M$ motor mechanical time constant in seconds.

Stepper Motors.—In a stepper motor, power is applied to a wound stator, causing the brushless rotor to change position to correspond with the internal magnetic field. The rotor maintains its position relative to the internal magnetic field at all times. In its most common mode of operation, the stepper motor is energized by an electronic controller whose current output to the motor windings defines the position of the internally generated magnetic field. Applying a command pulse to the controller will change the motor currents to reposition the rotor. A series of pulses, accompanied by a direction command, will cause rotation in uniformly spaced steps in the specified direction.

If the pulses are applied at a sufficiently high frequency, the rotor will be carried along with the system's inertia and will rotate relatively uniformly but with a modulated velocity. At the other extreme, the response to a single pulse will be a step followed by an overshoot and a decaying oscillation. Where the application cannot permit the oscillation, damping can be included in the controller.

Stepper motors are often preferred because positions of the rotor are known from the number of pulses and the step size. An initial index point is required as an output position reference, and care is required in the electronic circuits to avoid introducing random pulses that will cause false positions. As a minimum, the output index point on an appropriate shaft can verify the step count during operation.

Gearing.—In a closed-loop system, gearing may be used to couple a high-speed, low-torque motor to a lower-speed, higher-torque load. The gearing must meet requirements for accuracy, strength, and reliability to suit the application. In addition, the closed loop requires minimum backlash at the point where the feedback sensor is coupled. In a velocity-controlled system, the feedback sensor is a tachometer that is usually coupled directly to the rotor shaft. Backlash between motor and tachometer, as well as torsional compliance, must be minimized for stable operation of a high-performance system. Units combining motor and tachometer on a single shaft can usually be purchased as an assembly.

By contrast, a positioning system may use a position feedback sensor that is closely coupled to the shaft being positioned. As with the velocity system, backlash between the motor and feedback sensor must be minimized for closed-loop stability. Antibacklash gearing is frequently used between the gearing and the position feedback sensor. When the position

www.EngineeringEBooksPdf.com

feedback sensor is a limited rotation device, it may be coupled to a gear that turns faster than the output gear to allow use of its full range. Although this step-up gearing enhances it, accuracy is ultimately limited by the errors in the intermediate gearing between the position sensor and the output.

When an appreciable load inertia is being driven, it is important that the mechanical stiffness between the position sensor coupling point and the load be high enough to avoid natural torsional resonances in the passband.

Feedback Transducers.—Controlled variables are measured by feedback transducers and are the key to accuracy in operation of closed-loop systems. When the accuracy of a carefully designed control system approaches the accuracy of the feedback transducer, the need for precision in the other system components is reduced.

Transducers may measure the quantity being controlled in digital or analog form, and are available for many different parameters such as pressure and temperature, as well as distance traveled or degrees of rotation. Machine designers generally need to measure and control linear or rotary motion, velocity, position, and sometimes acceleration. Although some transducers are nonlinear, a linear relationship between the measured variable and the (usually electrical) output is most common.

Output characteristics of an analog linear-position transducer are shown in Fig. 2. By dividing errors into components, accuracy can be increased by external adjustments, and slope error and zero offsets are easily trimmed in. Nonlinearity is controlled by the manufacturer. In Fig. 2 are seen the discrete error components that can be distinguished because of the ease with which they can be canceled out individually by external adjustments. The most common compensation is for zero-position alignment, so that when the machine has been set to the start position for a sequence, the transducer can be positioned to read zero output. Alternatively, with all components in fixed positions, a small voltage can be inserted in series with the transducer output for a very accurate alignment of mechanical and electrical zeros. This method helps in canceling long-term drift, particularly in the mechanical elements.

The second most common adjustment of a position transducer is of its output gradient, that is, transducer output volts per degree. Depending on the type of analog transducer, it is usually possible to add a small adjustment to the electrical input, to introduce a proportional change in output gradient. As with the zero-position adjustment, the gradient may be set very accurately initially and during periodic maintenance. The remaining errors shown in Fig. 2, such as intrinsic nonlinearity or nonconformity, result from limitations in design and manufacture of the transducer.

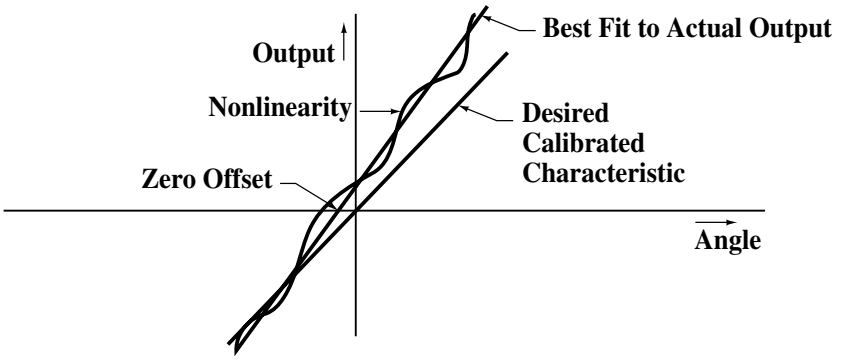

Fig. 3. Output Characteristics of a General Linear Position Transducer

Greater accuracy can be achieved in computer-controlled systems by using the computer to cancel out transducer errors. The system's mechanical values and corresponding transducer values are stored in a lookup table in the computer and referred to as necessary.

www.EngineeringEBooksPdf.com

Accuracies approaching the inherent repeatability and stability of the system can thus be secured. If necessary, recalibration can be performed at frequent intervals.

Analog Transducers.— The simplest analog position transducer is the resistance potentiometer, the resistance element in which is usually a deposited-film rather than a wire-wound type. Very stable resistance elements based on conductive plastics, with resolution to a few microinches and operating lives in the 100 million rotations, are available, capable of working in severe environments with high vibrations and shock and at temperatures of 150 to 200°C. Accuracies of a few hundredths, and stability of thousandths, of a per cent, can be obtained from these units by trimming the plastics resistance element as a function of angle.

Performance of resistance potentiometers deteriorates when they operate at high speeds, and prolonged operation at speeds above 10 rpm causes excessive wear and increasing output noise. An alternative to the resistance potentiometer is the variable differential transformer, which uses electrical coupling between ac magnetic elements to measure angular or linear motion without sliding contacts. These units have unlimited resolution with accuracy comparable to the best resistance potentiometers but are more expensive and require compatible electronic circuits.

A variable differential transformer needs ac energization, so an ac source is required. A precision demodulator is frequently used to change the ac output to dc. Sometimes the ac output is balanced against an ac command signal whose input is derived from the same ac source. In dealing with ac signals, phase-angle matching and an accurate amplitude-scale factor are required for proper operation. Temperature compensation also may be required, primarily due to changes in resistance of the copper windings. Transducer manufacturers will supply full sets of compatible electronic controls.

Synchros and Resolvers.— Synchros and resolvers are transducers that are widely used for sensing of angles at accuracies down to 10 to 20 arc-seconds. More typically, and at much lower cost, their accuracies are 1 to 2 arc-minutes. Cost is further reduced when accuracies of 0.1 degree or higher are acceptable.

Synchros used as angle-position transducers are made as brush types with slip rings and in brushless types. These units can rotate continuously at high speeds, the operating life of brushless designs being limited only by the bearing life. Synchros have symmetrical three-wire stator windings that facilitate transmission of angle data over long distances (thousands of feet). Such a system is also highly immune to noise and coupled signals. Practically the only trimming required for very long line systems is matching the line-to-line capacitances.

Because synchros can rotate continuously, they can be used in multispeed arrangements, where, for example, full-scale system travel may be represented by 36 or 64 full rotations. When reduced by gearing to a single, full-scale turn, a synchro's electrical inaccuracy is the typical 0.1° error divided by 36 or 64 or whatever gear ratio is used. This error is insignificant compared with the error of the gearing coupling the high-speed synchro and the single speed (1 rotation for full scale) output shaft. The accuracy is dependable and stable, using standard synchros and gearing.

Hydraulic and Pneumatic Systems

In Fig. 1 is shown a schematic of a hydraulic cylinder and the relationships between force and area that govern all hydraulic systems. Hydraulic actuators that drive the load may be cylinders or motors, depending on whether linear or rotary motion is required. The load must be defined by its torque-speed characteristics and inertia, and a suitable hydraulic actuator selected before the remaining system components can be chosen. Fluid under pressure and suitable valves are needed to control motion. Both single- and double-acting hydraulic cylinders are available, and the latter type is seen in Fig. 1.

www.EngineeringEBooksPdf.com

Pressure can be traded off against velocity, if desired, by placing a different effective area at each side of the piston. The same pressure on a smaller area will move the piston at a higher speed but lower force for a given rate of fluid delivery. The cylinder shown in Fig. 1 can drive loads in either direction. The simple formulas of plane geometry relate cylinder areas, force, fluid flow, and rate of movement. Other configurations can develop equal forces and speeds in both directions.

The rotary equivalent of the cylinder is the hydraulic motor, which is defined by the fluid displacement required to turn the output shaft through one revolution, by the output torque, and by the load requirements of torque and speed. Output torque is proportional to fluid pressure, which can be as high as safety permits. Output speed is defined by the number of gallons per minute supplied to the motor. As an example, if 231 cu. in. = 1 gallon, an input of 6 gallons/min (gpm) with a 5-cu. in. displacement gives a mean speed of $6 \times 231/5 = 277$ rpm. The motor torque must be defined by lb-in. per 100 $lb_f/in.^2$ (typically) from which the required pressure can be determined. Various motor types are available.

Hydraulic Pumps.—The most-used hydraulic pump is the positive-displacement type, which delivers a fixed amount of fluid for every cycle. These pumps are also called hydrostatic because they deliver energy by static pressure rather than by the kinetic energy of a moving fluid. Positive-displacement pumps are rated by the gpm delivered at a stated speed and by the maximum pressure, which are the key parameters defining the power capacity of the hydraulic actuator. Delivered gpm are reduced under load due to leakage, and the reduction is described by the volumetric efficiency, which is the ratio of actual to theoretical output.

Hydraulic Fluids.—The hydraulic fluid is the basic means of transmitting power, and it also provides lubrication and cooling when passed through a heat exchanger. The fluid must be minimally compressible to avoid springiness and delay in response. The total system inertia reacts with fluid compliance to generate a resonant frequency, much as inertia and mechanical compliance react in an electromechanical system. Compliance must be low enough that resonances do not occur in the active bandwidth of the servomechanism, and that unacceptable transients do not occur under shock loads. Seal friction and fluid viscosity tend to damp out resonant vibrations. Shock-absorbing limit stops or cushions are usually located at the travel limits to minimize transient impact forces.

F = force (lb) = pressure × area

P_1 and P_2 = line pressure on either side of piston in $lb_f/in.^2$

d_1 and d_2 = diameters of piston rod and piston in in.

$$F_1 = \frac{\pi}{4}(d_2^2 - d_1^2) \times P_1 = 0.7854P_1(d_2^2 - d_1^2)$$

$$F_2 = \frac{\pi}{4} d_2^2 P_2 = 0.7854P_2 d_2^2$$

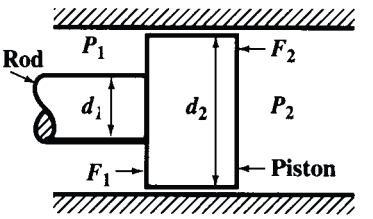

Fig. 1. Elementary Hydraulic Force/Area Formulas

Hydraulic fluids with special additives for lubrication minimize wear between moving parts. An auxiliary function is prevention of corrosion and pitting. Hydraulic fluids must also be compatible with gaskets, seals, and other nonmetallic materials.

Viscosity is another critical parameter of hydraulic fluids as high viscosity means high resistance to fluid flow with a corresponding power loss and heating of the fluid, pressure drop in the hydraulic lines, difficulty in removing bubbles, and sometimes overdamped operation. Unfortunately, viscosity falls very rapidly with increasing temperature, which can lead to reduction of the lubrication properties and excessive wear as well as increasing leakage. For hydraulic actuators operating at very low temperatures, the fluid pour point is important. Below this temperature, the hydraulic fluid will not flow. Design guidelines similar to those used with linear or rotating bearings are applicable in these conditions.

www.EngineeringEBooksPdf.com

Fire-resistant fluids are available for use in certain conditions such as in die casting, where furnaces containing molten metal are often located near hydraulic systems.

A problem with hydraulic systems that is absent in electromechanical systems is that of dirt, air bubbles, and contaminants in the fluid. Enclosed systems are designed to keep out contaminants, but the main problem is with the reservoir or fluid storage unit. A suitable sealer must be used in the reservoir to prevent corrosion and a filter should be used during filling. Atmospheric pressure is required on the fluid surface in the reservoir except where a pressurized reservoir is used. Additional components include coarse and fine filters to remove contaminants and these filters may be rated to remove micron sized particles (1 micron = 0.00004 in.).

Very fine filters are sometimes used in high-pressure lines, where dirt might interfere with the operation of sensitive valves. Where a high-performance pump is used, a fine filter is a requirement. Usually, only coarse filters are used on fluid inlet lines because fine filters might introduce excessive pressure drop.

Aside from the reservoir used for hydraulic fluid storage, line connections, fittings, and couplings are needed. Expansion of these components under pressure increases the mechanical compliance of the system, reducing the frequencies of any resonances and possibly interfering with the response of wide-band systems.

Formulas relating fluid flow and mechanical power follow. These formulas supplement the general force, torque, speed, and power formulas of mechanical systems.

$$F = P \times A$$

$$A = 0.7854 \times d^2$$

$$hp = 0.000583q \times \text{pressure in } \text{lb}_\text{f}/\text{in}^2$$

1 gallon of fluid flow/min at 1 $\text{lb}_\text{f}/\text{in}^2$ pressure = 0.000582 hp.

For rotary outputs,

$$hp = \text{torque} \times \text{rpm}/63{,}025$$

where torque is in lb-in. (Theoretical hp output must be multiplied by the efficiency of the hydraulic circuits to determine actual output.)

In the preceding equations,

P = pressure in $\text{lb}_\text{f}/\text{in}^2$

A = piston area in in^2

F = force in lb

q = fluid flow in gallons/min

d = piston diameter in inches

Hydraulic and Pneumatic Control Systems.—Control systems for hydraulic and pneumatic circuits are more mature than those for electromechanical systems because they have been developed over many more years. Hydraulic components are available at moderate prices from many sources. Although their design is complex, application and servicing of these systems are usually more straightforward than with electromechanical systems.

Electromechanical and hydraulic/pneumatic systems may be analyzed by similar means. The mathematical requirements for accuracy and stability are analogous, as are most performance features, although nonlinearities are caused by different physical attributes. Nonlinear friction, backlash, and voltage and current limiting are common to both types of system, but hydraulic/pneumatic systems also have the behavior characteristics of fluid-driven systems such as thermal effects and fluid flow dynamics including turbulence, leakage caused by imperfect seals, and contamination.

Both control types require overhead equipment that does not affect performance but adds to overall cost and complexity. For instance, electromechanical systems require electrical power sources and power control components, voltage regulators, fuses and circuit breakers, relays and switches, connectors, wiring and related devices. Hydraulic/pneumatic sys-

www.EngineeringEBooksPdf.com

tems require fluid stored under pressure, motor-driven pumps or compressors, valves, pressure regulators/limiters, piping and fasteners, as well as hydraulic/pneumatic motors and cylinders. Frequently, the optimum system is selected on the basis of overhead equipment already available.

Electromechanical systems are generally slower and heavier than hydraulic systems and less suited to controlling heavy loads. The bandwidths of hydraulic control systems can respond to input signals of well over 100 Hz as easily as an electromechanical system can respond to, say, 10 to 20 Hz. Hydraulic systems can drive very high torque loads without intermediate transmissions such as the gear trains often used with electromechanical systems. Also, hydraulic/pneumatic systems using servo valves and piston/cylinder arrangements are inherently suited to linear motion operation, whereas electromechanical controls based on conventional electrical machines are more naturally suited to driving rotational loads.

Until recently, electromechanical systems were limited to system bandwidths of about 10 Hz, with power outputs of a few hundred watts. However, their capabilities have now been sharply extended through the use of rare-earth motor magnets having much higher energies than earlier designs. Similarly, semiconductor power components deliver much higher output power at lower prices than earlier equipment. Electromechanical control systems are now suited to applications of more than 100 hp with bandwidths up to 40 Hz and sometimes up to 100 Hz.

Although much depends on the specific design, the edge in reliability, even for high-power, fast-response needs, is shifting toward electromechanical systems. Basically, there are more things that can go wrong in hydraulic/pneumatic systems, as indicated by the shift to more electrical systems in aircraft.

Hydraulic Control Systems.—Using essentially incompressible fluid, hydraulic systems are suited to a wide range of applications, whereas pneumatic power is generally limited to simpler uses. In Fig. 2 are shown the essential features of a simple linear hydraulic control system and a comparable system for driving a rotating load.

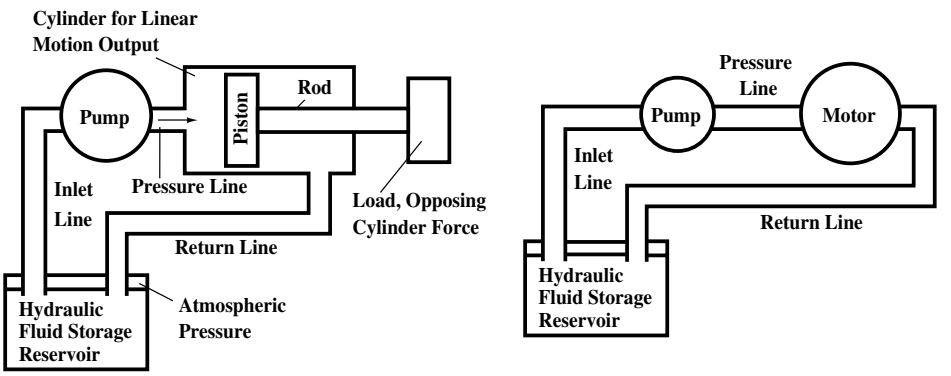

Fig. 2. (left) A Simple Linear Hydraulic Control System in Which the Load Force Returns the Piston and (right) a Comparable System for Driving a Rotating Load

Hydraulic controls of the type shown have fast response and very high load capacities. In a linear actuator, for example, each $lb_f/in.^2$ of system pressure acts against the area of the piston to generate the force applied. Hydraulic pressures of up to 3000 $lb_f/in.^2$ are readily obtained from hydraulic pumps, so that cylinders can exert forces of hundreds of tons without the need for speed-reducing transmission systems to increase the force. The hydraulic fluid distributes heat, so it helps cool the system.

Systems similar to those in Fig. 2 can be operated in open- or closed-loop modes. Open-loop operation can be controlled by programming units that initiate each step by operating relays, limit switches, solenoid valves, and other components to generate the forces over

www.EngineeringEBooksPdf.com

the required travel ranges. Auxiliary components are used to ensure safe operation and make such systems flexible and reliable, as shown in Fig. 3.

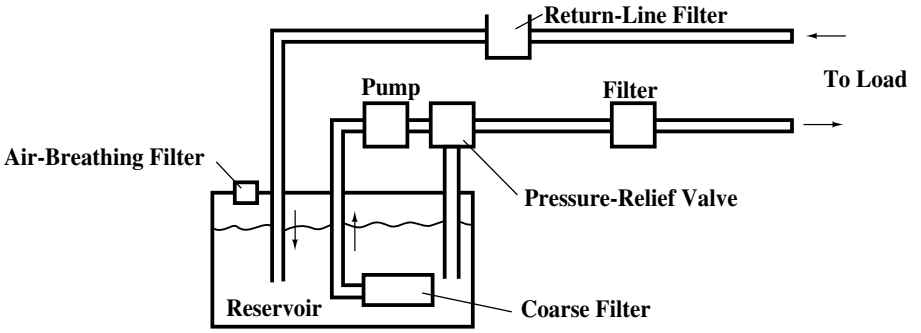

Fig. 3. Some of the Auxiliary Components Used in a Practical Hydraulic System

In the simplest mode, whether open- or closed-loop, hydraulic system operation may be discontinuous or proportional. Discontinuous operation, sometimes called bang-bang, or on-off, works well, is widely used in low- to medium-accuracy systems, and is easy to maintain. In this closed-loop mode, accuracy is limited; if the response to error is set too high, the system will oscillate between on-off modes, with average output at about the desired value. This oscillation, however, can be noisy, introduces system transients, and may cause rapid wear of system components.

Another factor to be considered in on-off systems is the shock caused by sudden opening and closing of high-pressure valves, which introduce transient pulses in the fluid flow and can cause high stresses in components. These problems can be addressed by the use of pressure-limiting relief valves and other units.

Proportional Control Systems.—Where the highest accuracy is required, perhaps in two directions, and with aiding or opposing forces or torques, a more sophisticated proportional control, closed-loop system is preferred. As shown in Fig. 4, the amplifier and electric servomotor used in electromechanical closed-loop systems is replaced in the closed-loop hydraulic system by an electronically controlled servo-valve. In its simplest form, the valve uses a linear motor to position the spool that determines the flow path for the hydraulic fluid. In some designs, the linear motor may be driven by a solenoid against a bias spring on the value spool. In other arrangements, the motor may be a bidirectional unit that permits a fluid flow depending on the polarity and amplitude of the voltage supplied to the motor.

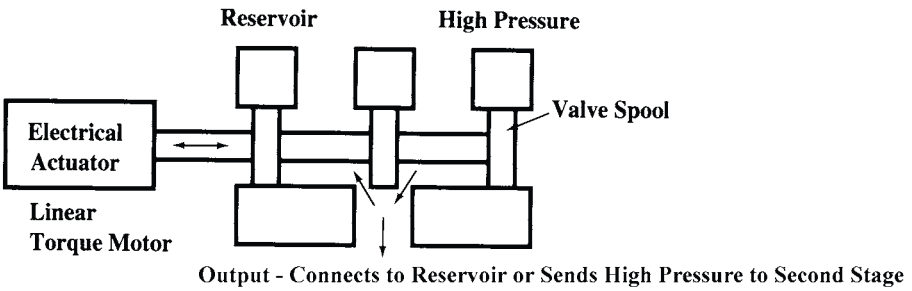

Fig. 4.

Such designs can be used in proportional control systems to achieve smooth operation and minimum nonlinearities, and will give the maximum accuracy required by the best machine tool applications. Where very high power must be controlled, use is often made of a two-stage valve in which the output from the first stage is used to drive the second-stage valve, as shown in Fig. 5.

www.EngineeringEBooksPdf.com

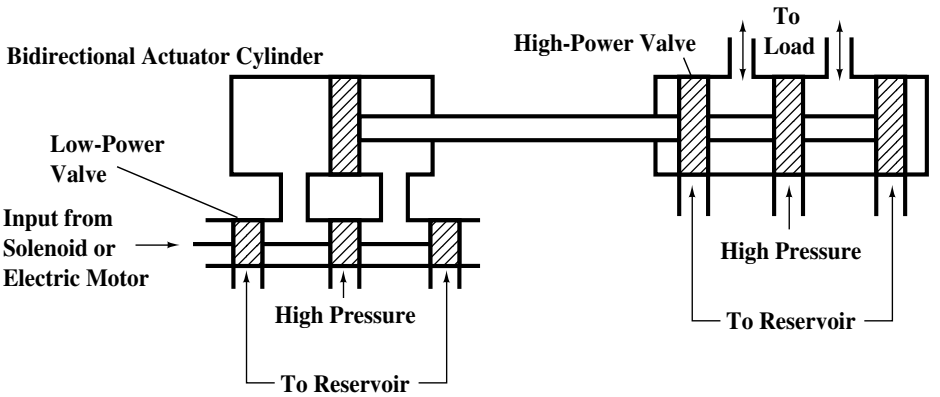

Fig. 5. Two-Stage Valve for Large-Power Control from a Low-Power Input

Electronic Controls.— An error-sensing electronic amplifier drives the solenoid motor of Fig. 5, which provides automatic output correction in a closed-loop system. The input is an ideal place to introduce electrical control features, adding greatly to the versatility of the control system. The electronic amplifier can provide the necessary driving power using pulse-width modulation as required, for minimum heating. The output can respond to signals in the low-microvolt range.

A major decision is whether to use analog or digital control. Although analog units are simple, they are much less versatile than their digital counterparts. Digital systems can be readjusted for total travel, speed, and acceleration by simple reprogramming. Use of appropriate feedback sensors can match accuracy to any production requirement, and a single digital system can be easily adapted to a great variety of similar applications. This adaptability is an important cost-saving feature for moderate-sized production runs. Modern microprocessors can integrate the operation of sets of systems.

Because nonlinearities and small incremental motions are easy to implement, digital systems are capable of very smooth acceleration, which avoids damaging shocks and induced leaks, and enhances reliability so that seals and hose connections last longer. The accuracy of digital control systems depends on transducer availability, and a full range of such devices has been developed and is now available.

Other features of digital controls are their capacity for self-calibration, easy digital readout, and periodic self-compensation. For example, it is easy to incorporate backlash compensation. Inaccuracies can be corrected by using lookup tables that may themselves be updated as necessary. Digital outputs can be used as part of an inspection plan, to indicate need for tool changing, adjustment or sharpening, or for automatic record keeping. Despite continuing improvements in analog systems, digital control of hydraulic systems is favored in large plants.

Pneumatic Systems.— Hydraulic systems transmit power by means of the flow of an essentially incompressible fluid. Pneumatic systems use a highly compressible gas. For this reason, a pneumatic system is slower in responding to loads, especially sudden output loads, than a hydraulic system. Similarly, torque or force requires time and output motion to build up. Response to sudden output loads shows initial overshoot. Much more complex networks or other damping means are required to develop stable response in closed-loop systems. On the other hand, there are no harmful shock waves analogous to the transients that can occur in hydraulic systems, and pneumatic system components last comparatively longer.

Notwithstanding their performance deficiencies, pneumatic systems have numerous desirable features. Pneumatic systems avoid some fire hazards compared with the most preferred hydraulic fluids. Air can be vented to the atmosphere so a flow line only is needed, reducing the complexity, cost, and weight of the overall system. Pneumatic lines,

www.EngineeringEBooksPdf.com

couplings, and fittings are lighter than their hydraulic counterparts, often a significant advantage. The gaseous medium also is lighter than hydraulic fluid, and pneumatic systems are usually easier to clean, assemble, and generally maintain. Fluid viscosity and its temperature variations are virtually negligible with pneumatic systems.

Among drawbacks with pneumatics are that lubrication must be carefully designed in, and more power is needed to achieve a desired pressure when the fluid medium is a compressible gas. Gas under high pressure can cause an explosion if its storage tank is damaged, so storage must have substantial safety margins. Gas compressibility makes pneumatic systems 1 or 2 orders of magnitude slower than hydraulic systems.

The low stiffness of pneumatic systems is another indicator of the long response time. Resonances occur between the compressible gas and equivalent system inertias at lower frequencies. Even the relatively low speed of sound in connecting lines contributes to response delay, adding to the difficulty of closed-loop stabilization. Fortunately, it is possible to construct pneumatic analogs to electrical networks to simplify stabilization at the exact point of the delays. Such pneumatic stabilizing means are commercially available and are important elements of closed-loop pneumatic control systems.

In contrast with hydraulic systems, where speed may be controlled by varying pump output, pneumatic system control is almost exclusively by valves, which control the flow from a pneumatic accumulator or pressure source. The pressure is maintained between limits by an intermittently operated pump. Low-pressure outlet ports must be large enough to accommodate the high volume of the expanded gas. In Fig. 6 is shown a simplified system for closed-loop position control applied to an air cylinder, in which static accuracy is controlled by the position sensor. Proper design requires a good theoretical analysis and attention to practical design if good, stable, closed-loop response is to be achieved.

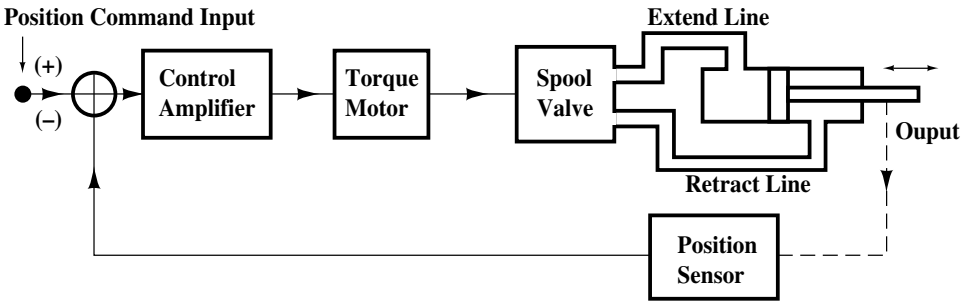

Fig. 6. A Pneumatic Closed-Loop Linear Control System

Strength and Properties of Wire Rope

Wire Rope Construction.—Essentially, a wire rope is made up of a number of strands laid helically about a metallic or non-metallic core. Each strand consists of a number of wires also laid helically about a metallic or non-metallic center. Various types of wire rope have been developed to meet a wide range of uses and operating conditions. These types are distinguished by the kind of core; the number of strands; the number, sizes, and arrangement of the wires in each strand; and the way in which the wires and strands are wound or laid about each other. The following descriptive material is based largely on information supplied by the Bethlehem Steel Co.

Rope Wire Materials: Materials used in the manufacture of rope wire are, in order of increasing strength: iron, phosphor bronze, traction steel, plow steel, improved plow steel, and bridge rope steel. Iron wire rope is largely used for low-strength applications such as elevator ropes not used for hoisting, and for stationary guy ropes.

Phosphor bronze wire rope is used occasionally for elevator governor-cable rope and for certain marine applications as life lines, clearing lines, wheel ropes and rigging.

Traction steel wire rope is used primarily as hoist rope for passenger and freight elevators of the traction drive type, an application for which it was specifically designed.

Ropes made of galvanized wire or wire coated with zinc by the electro-deposition process are used in certain applications where additional protection against rusting is required. As will be noted from the tables of wire-rope sizes and strengths, the breaking strength of galvanized wire rope is 10 per cent less than that of ungalvanized (bright) wire rope. Bethanized (zinc-coated) wire rope can be furnished to bright wire rope strength when so specified.

Galvanized carbon steel, tinned carbon steel, and stainless steel are used for small cords and strands ranging in diameter from $\frac{1}{64}$ to $\frac{3}{8}$ inch and larger.

Marline clad wire rope has each strand wrapped with a layer of tarred marline. The cladding provides hand protection for workers and wear protection for the rope.

Rope Cores: Wire-rope cores are made of fiber, cotton, asbestos, polyvinyl plastic, a small wire rope (independent wire-rope core), a multiple-wire strand (wire-strand core) or a cold-drawn wire-wound spring.

Fiber (manila or sisal) is the type of core most widely used when loads are not too great. It supports the strands in their relative positions and acts as a cushion to prevent nicking of the wires lying next to the core.

Cotton is used for small ropes such as sash cord and aircraft cord.

Asbestos cores can be furnished for certain special operations where the rope is used in oven operations.

Polyvinyl plastics cores are offered for use where exposure to moisture, acids, or caustics is excessive.

Wire-strand core often referred to as WSC, consists of a multiple-wire strand that may be the same as one of the strands of the rope. It is smoother and more solid than the independent wire rope core and provides a better support for the rope strands.

The *independent wire rope core*, often referred to as IWRC, is a small 6×7 wire rope with a wire-strand core and is used to provide greater resistance to crushing and distortion of the wire rope. For certain applications it has the advantage over a wire-strand core in that it stretches at a rate closer to that of the rope itself.

Wire ropes with wire-strand cores are, in general, less flexible than wire ropes with independent wire-rope or non-metallic cores.

Ropes with metallic cores are rated $7\frac{1}{2}$ per cent stronger than those with non-metallic cores.

www.EngineeringEBooksPdf.com

Wire-Rope Lay: The lay of a wire rope is the direction of the helical path in which the strands are laid and, similarly, the lay of a strand is the direction of the helical path in which the wires are laid. If the wires in the strand or the strands in the rope form a helix similar to the threads of a right-hand screw, i.e., they wind around to the right, the lay is called right hand and, conversely, if they wind around to the left, the lay is called left hand. In the *regular lay*, the wires in the strands are laid in the opposite direction to the lay of the strands in the rope. In right-regular lay, the strands are laid to the right and the wires to the left. In left-regular lay, the strands are laid to the left, the wires to the right. In *Lang lay*, the wires and strands are laid in the same direction, i.e., in right Lang lay, both the wires and strands are laid to the right and in left Lang they are laid to the left.

Alternate lay ropes having alternate right and left laid strands are used to resist distortion and prevent clamp slippage, but because other advantages are missing, have limited use.

The regular lay wire rope is most widely used and right regular lay rope is customarily furnished. Regular lay rope has less tendency to spin or untwist when placed under load and is generally selected where long ropes are employed and the loads handled are frequently removed. Lang lay ropes have greater flexibility than regular lay ropes and are more resistant to abrasion and fatigue.

In preformed wire ropes the wires and strands are preshaped into a helical form so that when laid to form the rope they tend to remain in place. In a non-preformed rope, broken wires tend to "wicker out" or protrude from the rope and strands that are not seized tend to spring apart. Preforming also tends to remove locked-in stresses, lengthen service life, and make the rope easier to handle and to spool.

Strand Construction: Various arrangements of wire are used in the construction of wire rope strands. In the simplest arrangement six wires are grouped around a central wire thus making seven wires, all of the same size. Other types of construction known as "filler-wire," Warrington, Seale, etc. make use of wires of different sizes. Their respective patterns of arrangement are shown diagrammatically in the table of wire weights and strengths.

Specifying Wire Rope.—In specifying wire rope the following information will be required: length, diameter, number of strands, number of wires in each strand, type of rope construction, grade of steel used in rope, whether preformed or not preformed, type of center, and type of lay. The manufacturer should be consulted in selecting the best type of wire rope for a new application.

Properties of Wire Rope.—Important properties of wire rope are strength, wear resistance, flexibility, and resistance to crushing and distortion.

Strength: The strength of wire rope depends upon its size, kind of material of which the wires are made and their number, the type of core, and whether the wire is galvanized or not. Strengths of various types and sizes of wire ropes are given in the accompanying tables together with appropriate factors to apply for ropes with steel cores and for galvanized wire ropes.

Wear Resistance: When wire rope must pass back and forth over surfaces that subject it to unusual wear or abrasion, it must be specially constructed to give satisfactory service.

Such construction may make use of 1) relatively large outer wires; 2) Lang lay in which wires in each strand are laid in the same direction as the strand; and 3) flattened strands.

The object in each type is to provide a greater outside surface area to take the wear or abrasion. From the standpoint of material, improved plow steel has not only the highest tensile strength but also the greatest resistance to abrasion in regularly stocked wire rope.

www.EngineeringEBooksPdf.com

Flexibility: Wire rope that undergoes repeated and severe bending, such as in passing around small sheaves and drums, must have a high degree of flexibility to prevent premature breakage and failure due to fatigue. Greater flexibility in wire rope is obtained by

1) using small wires in larger numbers; 2) using Lang lay; and 3) preforming, that is, the wires and strands of the rope are shaped during manufacture to fit the position they will assume in the finished rope.

Resistance to Crushing and Distortion: Where wire rope is to be subjected to transverse loads that may crush or distort it, care should be taken to select a type of construction that will stand up under such treatment.

Wire rope designed for such conditions may have 1) large outer wires to spread the load per wire over a greater area; and 2) an independent wire core or a high-carbon cold-drawn wound spring core.

Standard Classes of Wire Rope.—Wire rope is commonly designated by two figures, the first indicating the number of strands and the second, the number of wires per strand, as: 6×7, a six-strand rope having seven wires per strand, or 8×19, an eight-strand rope having 19 wires per strand. When such numbers are used as designations of standard wire rope classes, the second figure in the designation may be purely nominal in that the number of wires per strand for various ropes in the class may be slightly less or slightly more than the nominal as will be seen from the following brief descriptions. (For ropes with a wire strand core, a second group of two numbers may be used to indicate the construction of the wire core, as 1×21, 1×43, and so on.)

6×7 Class (Standard Coarse Laid Rope): Wire ropes in this class are for use where resistance to wear, as in dragging over the ground or across rollers, is an important requirement. Heavy hauling, rope transmissions, and well drilling are common applications. These wire ropes are furnished in right regular lay and occasionally in Lang lay. The cores may be of fiber, independent wire rope, or wire strand. Since this class is a relatively stiff type of construction, these ropes should be used with large sheaves and drums. Because of the small number of wires, a larger factor of safety may be called for.

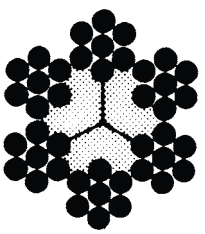

Fig. 1a.
6×7 with fiber core

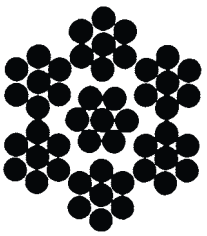

Fig. 1b.
6×7 with 1×7 WSC

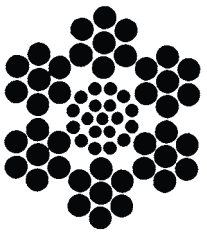

Fig. 1c.
6×7 with 1×19 WSC

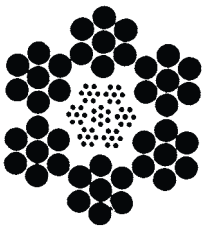

Fig. 1d.
6×7 with IWRC

As shown in Figs. 1a through Figs. 1d, this class includes a 6×7 construction with fiber core: a 6×7 construction with 1×7 wire strand core (sometimes called 7×7); a 6×7 construction with 1×19 wire strand core; and a 6×7 construction with independent wire rope core. Table 1 provides strength and weight data for this class.

Two special types of wire rope in this class are: aircraft cord, a 6×6 or 7×7 Bethanized wire rope of high tensile strength and sash cord, a 6×7 iron rope used for a variety of purposes where strength is not an important factor.

6 × 19 Class (Standard Hoisting Rope): This rope is the most popular and widely used class. Ropes in this class are furnished in regular or Lang lay and may be obtained preformed or not preformed. Cores may be of fiber, independent wire rope, or wire strand. As can be seen from Table 2 and Figs. 2a through 2h, there are four common types: 6 × 25 filler wire construction with fiber core (not illustrated), independent wire core, or wire strand core (1 × 25 or 1 × 43); 6 × 19 Warrington construction with fiber core; 6 × 21 filler wire construction with fiber core; and 6 × 19, 6 × 21, and 6 × 17 Seale construction with fiber core.

6 × 37 Class (Extra Flexible Hoisting Rope): For a given size of rope, the component wires are of smaller diameter than those in the two classes previously described and hence have less resistance to abrasion. Ropes in this class are furnished in regular and Lang lay with fiber core or independent wire rope core, preformed or not preformed.

filler wire construction with fiber core or independent wire rope core, a special large shovel and dredge rope.

8 × 19 Class (Special Flexible Hoisting Rope): This rope is stable and smooth-running, and is especially suitable, because of its flexibility, for high speed operation with reverse bends. Ropes in this class are available in regular lay with fiber core.

As shown in Table 4 and Figs. 4a through 4d, there are four common types: 8 × 25 filler wire construction, the most flexible but the least wear resistant rope of the four types; Warrington type in 8 × 19 construction, less flexible than the 8 × 25; 8 × 21 filler wire construction, less flexible than the Warrington; and Seale type in 8 × 19 construction, which has the greatest wear resistance of the four types but is also the least flexible.

18 × 7 Non-rotating Wire Rope: This rope is specially designed for use where a minimum of rotating or spinning is called for, especially in the lifting or lowering of free loads with a single-part line. It has an inner layer composed of 6 strands of 7 wires each laid in left Lang lay over a fiber core and an outer layer of 12 strands of 7 wires each laid in right regular lay. The combination of opposing lays tends to prevent rotation when the rope is stretched. However, to avoid any tendency to rotate or spin, loads should be kept to at least one-eighth and preferably one-tenth of the breaking strength of the rope. Weights and strengths are shown in Table 5.

Flattened Strand Wire Rope: The wires forming the strands of this type of rope are wound around triangular centers so that a flattened outer surface is provided with a greater area than in the regular round rope to withstand severe conditions of abrasion. The triangular shape of the strands also provides superior resistance to crushing. Flattened strand wire

www.EngineeringEBooksPdf.com

rope is usually furnished in Lang lay and may be obtained with fiber core or independent wire rope core. The three types shown in Table 6 and Figs. 6a through 6c are flexible and are designed for hoisting work.

Flat Wire Rope: This type of wire rope is made up of a number of four-strand rope units placed side by side and stitched together with soft steel sewing wire. These four-strand units are alternately right and left lay to resist warping, curling, or rotating in service. Weights and strengths are shown in Table 7.

Simplified Practice Recommendations.—Because the total number of wire rope types is large, manufacturers and users have agreed upon and adopted a U.S. Simplified Practice Recommendation to provide a simplified listing of those kinds and sizes of wire rope which are most commonly used and stocked. These, then, are the types and sizes which are most generally available. Other types and sizes for special or limited uses also may be found in individual manufacturer's catalogs.

Sizes and Strengths of Wire Rope.—The data shown in Tables 1 through 7 have been taken from U.S. Simplified Practice Recommendation 198-50 but do not include those wire ropes shown in that Simplified Practice Recommendation which are intended primarily for marine use.

Wire Rope Diameter: The diameter of a wire rope is the diameter of the circle that will just enclose it, hence when measuring the diameter with calipers, care must be taken to obtain the largest outside dimension, taken across the opposite strands, rather than the smallest dimension across opposite “valleys” or “flats.” It is standard practice for the nominal diameter to be the minimum with all tolerances taken on the plus side. Limits for diam-

www.EngineeringEBooksPdf.com

eter as well as for minimum breaking strength and maximum pitch are given in Federal Specification for Wire Rope, RR-R—571a.

Wire Rope Strengths: The strength figures shown in the accompanying tables have been obtained by a mathematical derivation based on actual breakage tests of wire rope and represent from 80 to 95 per cent of the total strengths of the individual wires, depending upon the type of rope construction.

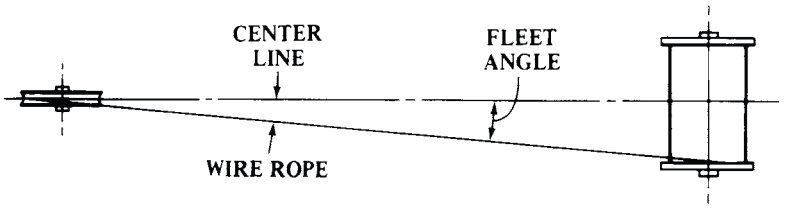
Safe Working Loads and Factors of Safety.—The maximum load for which a wire rope is to be used should take into account such associated factors as friction, load caused by bending around each sheave, acceleration and deceleration, and, if a long length of rope is to be used for hoisting, the weight of the rope at its maximum extension. The condition of the rope — whether new or old, worn or corroded — and type of attachments should also be considered.

Factors of safety for standing rope usually range from 3 to 4; for operating rope, from 5 to 12. Where there is the element of hazard to life or property, higher values are used.

www.EngineeringEBooksPdf.com

Installing Wire Rope.— The main precaution to be taken in removing and installing wire rope is to avoid kinking which greatly lessens the strength and useful life. Thus, it is preferable when removing wire rope from the reel to have the reel with its axis in a horizontal position and, if possible, mounted so that it will revolve and the wire rope can be taken off straight. If the rope is in a coil, it should be unwound with the coil in a vertical position as by rolling the coil along the ground. Where a drum is to be used, the rope should be run directly onto it from the reel, taking care to see that it is not bent around the drum in a direction opposite to that on the reel, thus causing it to be subject to reverse bending. On flat or smooth-faced drums it is important that the rope be started from the proper end of the drum. A right lay rope that is being overwound on the drum, that is, it passes over the top of the drum as it is wound on, should be started from the right flange of the drum (looking at the drum from the side that the rope is to come) and a left lay rope from the left flange.

When the rope is under wound on the drum, a right lay rope should be started from the left flange and a left lay rope from the right flange, so that the rope will spool evenly and the turns will lie snugly together.



Sheaves and drums should be properly aligned to prevent undue wear. The proper position of the main or lead sheave for the rope as it comes off the drum is governed by what is called the fleet angle or angle between the rope as it stretches from drum to sheave and an imaginary center-line passing through the center of the sheave groove and a point halfway between the ends of the drum. When the rope is at one end of the drum, this angle should not exceed one and a half to two degrees. With the lead sheave mounted with its groove on this center-line, a safe fleet angle is obtained by allowing 30 feet of lead for each two feet of drum width.

Sheave and Drum Dimensions: Sheaves and drums should be as large as possible to obtain maximum rope life. However, factors such as the need for lightweight equipment for easy transport and use at high speeds, may call for relatively small sheaves with consequent sacrifice in rope life in the interest of overall economy. No hard and fast rules can be laid down for any particular rope if the utmost in economical performance is to be obtained. Where maximum rope life is of prime importance, the following recommendations of Federal Specification RR-R-571a for minimum sheave or drum diameters D in terms of rope diameter d will be of interest. For 6×7 rope (six strands of 7 wires each) $D = 72d$; for 6×19 rope, $D = 45d$; for 6×25 rope, $D = 45d$; for 6×29 rope, $D = 30d$; for 6×37 rope, $D = 27d$; and for 8×19 rope, $D = 31d$.

Too small a groove for the rope it is to carry will prevent proper seating of the rope in the bottom of the groove and result in uneven distribution of load on the rope. Too large a groove will not give the rope sufficient side support. Federal Specification RR-R-571a recommends that sheave groove diameters be larger than the nominal rope diameters by the following minimum amounts: For ropes of $\frac{1}{4}$- to $\frac{5}{16}$-inch diameters, $\frac{1}{64}$ inch larger; for $\frac{3}{8}$- to $\frac{3}{4}$-inch diameter ropes, $\frac{1}{32}$ inch larger; for $\frac{13}{16}$- to $1\frac{1}{8}$-inch diameter ropes, $\frac{3}{64}$ inch larger; for $1\frac{3}{16}$- to $1\frac{1}{2}$-inch ropes, $\frac{1}{16}$ inch larger; for $1\frac{9}{16}$- to $2\frac{1}{4}$-inch ropes, $\frac{3}{32}$ inch larger; and for $2\frac{5}{16}$ and larger diameter ropes, $\frac{1}{8}$ inch larger. For new or regrooved sheaves these values should be doubled; in other words for $\frac{1}{4}$- to $\frac{5}{16}$-inch diameter ropes, the groove diameter should be $\frac{1}{32}$ inch larger, and so on.

www.EngineeringEBooksPdf.com

Drum or Reel Capacity: The length of wire rope, in feet, that can be spooled onto a drum or reel, is computed by the following formula, where

A = depth of rope space on drum, inches: $A = (H - D - 2Y) \div 2$

B = width between drum flanges, inches

D = diameter of drum barrel, inches

H = diameter of drum flanges, inches

K = factor from Table 8 for size of line selected

Y = depth not filled on drum or reel where winding is to be less than full capacity

L = length of wire rope on drum or reel, feet: $L = (A + D) \times A \times B \times K$

Table 8. Factors *K* Used in Calculating Wire Rope Drum and Reel Capacities

3/32	23.4	1/2	0.925	1 3/8	0.127
1/8	13.6	9/16	0.741	1 1/2	0.107
9/64	10.8	5/8	0.607	1 5/8	0.0886
5/32	8.72	11/16	0.506	1 3/4	0.0770
3/16	6.14	3/4	0.428	1 7/8	0.0675
7/32	4.59	13/16	0.354	2	0.0597
1/4	3.29	7/8	0.308	2 1/8	0.0532
5/16	2.21	1	0.239	2 1/4	0.0476
3/8	1.58	1 1/8	0.191	2 3/8	0.0419
7/16	1.19	1 1/4	0.152	2 1/2	0.0380

Note: The values of "*K*" allow for normal oversize of ropes, and the fact that it is practically impossible to "thread-wind" ropes of small diameter. However, the formula is based on uniform rope winding and will not give correct figures if rope is wound non-uniformly on the reel. The amount of tension applied when spooling the rope will also affect the length. The formula is based on the same number of wraps of rope in each layer, which is not strictly correct, but does not result in appreciable error unless the width (*B*) of the reel is quite small compared with the flange diameter (*H*).

Example: Find the length in feet of 9/16-inch diameter rope required to fill a drum having the following dimensions: $B = 24$ inches, $D = 18$ inches, $H = 30$ inches,

$$A = (30 - 18 - 0) \div 2 = 6 \text{ inches}$$

$$L = (6 + 18) \times 6 \times 24 \times 0.741 = 2560.0 \text{ or } 2560 \text{ feet}$$

The above formula and factors *K* allow for normal oversize of ropes but will not give correct figures if rope is wound non-uniformly on the reel.

Load Capacity of Sheave or Drum: To avoid excessive wear and groove corrugation, the radial pressure exerted by the wire rope on the sheave or drum must be kept within certain maximum limits. The radial pressure of the rope is a function of rope tension, rope diameter, and tread diameter of the sheave and can be determined by the following equation:

$$P = \frac{2T}{D \times d}$$

where P = Radial pressure in pounds per square inch (see Table 9)

T = Rope tension in pounds

D = Tread diameter of sheave or drum in inches

d = Rope diameter in inches

According to the Bethlehem Steel Co. the radial pressures shown in Table 9 are recommended as maximums according to the material of which the sheave or drum is made.

www.EngineeringEBooksPdf.com

Table 9. Maximum Radial Pressures for Drums and Sheaves

Type of Wire Rope	Drum or Sheave Material: Cast Iron	Cast Steel	Manganese Steel[a]	Type of Wire Rope	Drum or Sheave Material: Cast Iron	Cast Steel	Manganese Steel[a]
	Recommended Maximum Radial Pressures, psi				Recommended Maximum Radial Pressures, psi

All dimensions in inches. Data taken from *Wire Rope Users Manual*, 2nd ed., American Iron and Steel Institute, Washington, D. C. The values given in this table are applicable to grooves in sheaves and drums but are not generally suitable for pitch design, since other factors may be involved.

Rope Loads due to Bending: When a wire rope is bent around a sheave, the resulting bending stress s_b in the outer wire, and equivalent bending load P_b (amount that direct tension load on rope is increased by bending) may be computed by the following formulas:

$s_b = Ed_w \div D$; $P_b = s_b A$, where $A = d^2Q$. E is the modulus of elasticity of the wire rope (varies with the type and condition of rope from 10,000,000 to 14,000,000. An average value of 12,000,000 is frequently used), d is the diameter of the wire rope, d_w is the diameter of the component wire (for 6 × 7 rope, $d_w = 0.106d$; for 6 × 19 rope, $0.063d$; for 6 × 37 rope, $0.045d$; and for 8 × 19 rope, $d_w = 0.050d$). D is the pitch diameter of the sheave in inches, A is the metal cross-sectional area of the rope, and Q is a constant, values for which are: 6 × 7 (Fiber Core) rope, 0.380; 6 × 7 (IWRC or WSC), 0.437; 6 × 19 (Fiber Core), 0.405; 6 × 19 (IWRC or WSC), 0.475; 6 × 37 (Fiber Core), 0.400; 6 × 37 (IWRC), 0.470; 8 × 19 (Fiber Core), 0.370; and Flattened Strand Rope, 0.440.

Example: Find the bending stress and equivalent bending load due to the bending of a 6 × 19 (Fiber Core) wire rope of 1/2-inch diameter around a 24-inch pitch diameter sheave.

$$d_w = 0.063 \times 0.5 = 0.0315 \text{ in.} \qquad A = 0.5^2 \times 0.405 = 0.101 \text{ sq. in.}$$
$$s_b = 12{,}000{,}000 \times 0.0315 \div 24 = 15{,}750 \text{ lbs. per sq. in.}$$
$$P_b = 15{,}750 \times 0.101 = 1590 \text{ lbs.}$$

www.EngineeringEBooksPdf.com

Cutting and Seizing of Wire Rope.—Wire rope can be cut with mechanical wire rope shears, an abrasive wheel, an electric resistance cutter (used for ropes of smaller diameter only), or an acetylene torch. This last method fuses the ends of the wires in the strands. It is important that the rope be seized on either side of where the cut is to be made. Any annealed low carbon steel wire may be used for seizing, the recommended sizes being as follows: For a wire rope of ¼- to 15/16-inch diameter, use a seizing wire of 0.054-inch (No. 17 Steel Wire Gage); for a rope of 1- to 1⅝-inch diameter, use a 0.105-inch wire (No. 12); and for rope of 1¾- to 3½-inch diameter, use a 0.135-inch wire (No. 10). Except for preformed wire ropes, a minimum of two seizings on either side of a cut is recommended. Four seizings should be used on either side of a cut for Lang lay rope, a rope with a steel core, or a non-spinning type of rope.

The following method of seizing is given in Federal Specification for wire rope, RR-R-571a. Lay one end of the seizing wire in the groove between two strands of wire rope and wrap the other end tightly in a close helix over the portion in the groove. A seizing iron (round bar ½ to ⅝ inch diameter by 18 inches long) should be used to wrap the seizing tightly. This bar is placed at right angles to the rope next to the first turn or two of the seizing wire. The seizing wire is brought around the back of the seizing iron and wrapped loosely around the wire rope in the opposite direction to that of the seizing coil. As the seizing iron is now rotated around the rope it will carry the seizing wire snugly and tightly into place. When completed, both ends of the seizing should be twisted together tightly.

Maintenance of Wire Rope.—Heavy abrasion, overloading, and bending around sheaves or drums that are too small in diameter are the principal reasons for the rapid deterioration of wire rope. Wire rope in use should be inspected periodically for evidence of wear and damage by corrosion. Such inspections should take place at progressively shorter intervals over the useful life of the rope as wear tends to accelerate with use. Where wear is rapid, the outside of a wire rope will show flattened surfaces in a short time.

If there is any hazard involved in the use of the rope, it may be prudent to estimate the remaining strength and service life. This assessment should be done for the weakest point where the most wear or largest number of broken wires are in evidence. One way to arrive at a conclusion is to set an arbitrary number of broken wires in a given strand as an indication that the rope should be removed from service and an ultimate strength test run on the worn sample. The arbitrary figure can then be revised and rechecked until a practical working formula is arrived at. A piece of waste rubbed along the wire rope will help to reveal broken wires. The effects of corrosion are not easy to detect because the exterior wires may appear to be only slightly rusty, and the damaging effects of corrosion may be confined to the hidden inner wires where it cannot be seen. To prevent damage by corrosion, the rope should be kept well lubricated. Use of zinc coated wire rope may be indicated for some applications.

Periodic cleaning of wire rope by using a stiff brush and kerosene or with compressed air or live steam and relubricating will help to lengthen rope life and reduce abrasion and wear on sheaves and drums. Before storing after use, wire rope should be cleaned and lubricated.

Lubrication of Wire Rope.—Although wire rope is thoroughly lubricated during manufacture to protect it against corrosion and to reduce friction and wear, this lubrication should be supplemented from time to time. Special lubricants are supplied by wire rope manufacturers. These lubricants vary somewhat with the type of rope application and operating condition. Where the preferred lubricant can not be obtained from the wire rope manufacturer, an adhesive type of lubricant similar to that used for open gearing will often be found suitable. At normal temperatures, some wire rope lubricants may be practically solid and will require thinning before application. Thinning may be done by heating to 160 to 200 degrees F. or by diluting with gasoline or some other fluid that will allow the lubricant to penetrate the rope. The lubricant may be painted on the rope or the rope may be passed through a box or tank filled with the lubricant.

www.EngineeringEBooksPdf.com

Replacement of Wire Rope.—When an old wire rope is to be replaced, all drums and sheaves should be examined for wear. All evidence of scoring or imprinting of grooves from previous use should be removed and sheaves with flat spots, defective bearings, and broken flanges, should be repaired or replaced. It will frequently be found that the area of maximum wear is located relatively near one end of the rope. By cutting off that portion, the remainder of the rope may be salvaged for continued use. Sometimes the life of a rope can be increased by simply changing it end for end at about one-half the estimated normal life. The worn sections will then no longer come at the points that cause the greatest wear.

Wire Rope Slings and Fittings

Slings.—A few of the simpler sling arrangements or hitches as they are called, are shown in the accompanying illustration. Normally 6 × 19 Class wire rope is recommended where a diameter in the ¼-inch to 1⅛-inch range is to be used and 6 × 37 Class wire rope where a diameter in the 1¼-inch and larger range is to be used. However, the 6 × 19 Class may be used even in the larger sizes if resistance to abrasion is of primary importance and the 6 × 37 Class in the smaller sizes if greater flexibility is desired.

The *straight lift hitch*, Fig. 7a, is a straight connector between crane hook and load.

The *basket hitch* may be used with two hooks so that the sides are vertical as shown at Fig. 7b or with a single hook with sides at various angles with the vertical as shown at Fig. 7c, Fig. 7d, and Fig. 7e. As the angle with the vertical increases, a greater tension is placed on the rope so that for any given load, a sling of greater lifting capacity must be used.

The *choker hitch*, shown at Fig. 7f, is widely used for lifting bundles of items such as bars, poles, pipe, and similar objects. The choker hitch holds these items firmly, but the load must be balanced so that it rides safely. Since additional stress is imposed on the rope due to the choking action, the capacity of this type of hitch is 25 per cent less than that of the comparable straight lift. If two choker hitches are used at an angle, these angles must also be taken into consideration as with the basket hitches.

Wire Rope Fittings.—Many varieties of swaged fittings are available for use with wire rope and several industrial and aircraft types are shown in the accompanying illustration. Swaged fittings on wire rope have an efficiency (ability to hold the wire rope) of approximately 100 per cent of the catalogue rope strength. These fittings are attached to the end or body of the wire rope by the application of high pressure through special dies that cause the material of the fitting to "flow" around the wires and strands of the rope to form a union that is as strong as the rope itself. The more commonly used types, of swaged fittings range from ⅛- to ⅝-inch diameter sizes in industrial types and from the 1/16- to ⅝-inch sizes in aircraft types. These fittings are furnished attached to the wire strand, rope, or cable.

Applying Clips and Attaching Sockets.—In attaching U-bolt clips for fastening the end of a wire rope to form a loop, it is essential that the saddle or base of the clip bears against the longer or "live" end of the rope loop and the U-bolt against the shorter or "dead" end. The "U" of the clips should never bear against the live end of the rope because the rope may be cut or kinked. A wire-rope thimble should be used in the loop eye of the rope to prevent kinking when rope clips are used. The strength of a clip fastening is usually less than 80 percent of the strength of the rope. Table 10 gives the proper size, number, and spacing for each size of wire rope.

In attaching commercial sockets of forged steel to wire rope ends, the following procedure is recommended. The wire rope is seized at the end and another seizing is applied at a distance from the end equal to the length of the basket of the socket. As explained in a previous section, soft iron wire is used and particularly for the larger sizes of wire rope, it is important to use a seizing iron to secure a tight winding. For large ropes, the seizing should be several inches long.

Two legs at 45° with the vertical
Load capacity is 141% of the single rope in Fig. 7a.

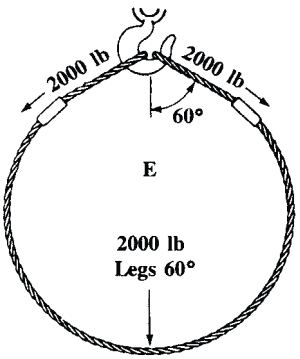

Fig. 7e. Basket Hitch
Two legs at 60° with the vertical
Load capacity is 100% of the single rope in Fig. 7a.

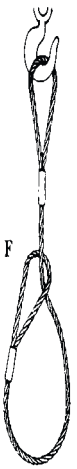

Fig. 7f. Choker Hitch
One leg vertical, with slip-through loop
Rated capacity is 75% of the single rope in Fig. 7a.

The end seizing is now removed and the strands are separated so that the fiber core can be cut back to the next seizing. The individual wires are then untwisted and "broomed out" and for the distance they are to be inserted in the socket are carefully cleaned with benzine, naphtha, or unleaded gasoline. The wires are then dipped into commercial muriatic (hydrochloric) acid and left (usually one to three minutes) until the wires are bright and clean or, if zinc coated, until the zinc is removed. After cleaning, the wires are dipped into a hot soda solution (1 pound of soda to 4 gallons of water at 175 degrees F. minimum) to neutralize the acid. The rope is now placed in a vise. A temporary seizing is used to hold the wire ends

Wire Rope Fittings

together until the socket is placed over the rope end. The temporary seizing is then removed and the socket located so that the ends of the wires are about even with the upper end of the basket. The opening around the rope at the bottom of the socket is now sealed with putty.

Table 10. Clips Required for Fastening Wire Rope End

A special high grade pure zinc is used to fill the socket. Babbit metal should not be used as it will not hold properly. For proper fluidity and penetration, the zinc is heated to a tem-

www.EngineeringEBooksPdf.com

perature in the 830- to 900-degree F. range. If a pyrometer is not available to measure the temperature of the molten zinc, a dry soft pine stick dipped into the zinc and quickly withdrawn will show only a slight discoloration and no zinc will adhere to it. If the wood chars, the zinc is too hot. The socket is now permitted to cool and the resulting joint is ready for use. When properly prepared, the strength of the joint should be approximately equal to that of the rope itself.

Crane Chain and Hooks

Material for Crane Chains.—The best material for crane and hoisting chains is a good grade of wrought iron, in which the percentage of phosphorus, sulfur, silicon, and other impurities is comparatively low. The tensile strength of the best grades of wrought iron does not exceed 46,000 pounds per square inch, whereas mild steel with about 0.15 per cent carbon has a tensile strength nearly double this amount. The ductility and toughness of wrought iron, however, is greater than that of ordinary commercial steel, and for this reason it is preferable for chains subjected to heavy intermittent strains, because wrought iron will always give warning by bending or stretching, before breaking. Another important reason for using wrought iron in preference to steel is that a perfect weld can be effected more easily. Heat-treated alloy steel is also widely used for chains. This steel contains carbon, 0.30 per cent, max; phosphorus, 0.045 per cent, max; and sulfur, 0.045 per cent, max. The selection and amounts of alloying elements are left to the individual manufacturers.

Strength of Chains.—When calculating the strength of chains it should be observed that the strength of a link subjected to tensile stresses is not equal to twice the strength of an iron bar of the same diameter as the link stock, but is a certain amount less, owing to the bending action caused by the manner in which the load is applied to the link. The strength is also reduced somewhat by the weld. The following empirical formula is commonly used for calculating the breaking load, in pounds, of wrought-iron crane chains: $W = 54{,}000D^2$ in which W = breaking load in pounds and D = diameter of bar (in inches) from which links are made. The working load for chains should not exceed one-third the value of W, and, it is often one-fourth or one-fifth of the breaking load. When a chain is wound around a casting and severe bending stresses are introduced, a greater factor of safety should be used.

Care of Hoisting and Crane Chains.—Chains used for hoisting heavy loads are subject to deterioration, both apparent and invisible. The links wear, and repeated loading causes localized deformations to form cracks that spread until the links fail. Chain wear can be reduced by occasional lubrication. The life of a wrought-iron chain can be prolonged by frequent annealing or normalizing unless it has been so highly or frequently stressed that small cracks have formed. If this condition is present, annealing or normalizing will not "heal" the material, and the links will eventually fracture. To anneal a wrought-iron chain, heat it to cherry-red and allow it to cool slowly. Annealing should be done every six months, and oftener if the chain is subjected to unusually severe service.

Maximum Allowable Wear at Any Point of Link

Chain Size (in.)	Maximum Allowable Wear (in.)	Chain Size (in.)	Maximum Allowable Wear (in.)	Chain Size (in.)	Maximum Allowable Wear (in.)
1/4 (9/32)	3/64	3/4	5/32	1 1/4	1/4
3/8	5/64	7/8	11/64	1 3/8	3/32
1/2	7/64	1	3/16	1 1/2	5/16
5/8	9/64	1 1/8	7/32	1 3/4	11/32

Source: Longshoring Industry, OSHA 2232, 1985.

Chains should be examined periodically for twists, as a twisted chain will wear rapidly. Any links that have worn excessively should be replaced with new ones, so that every link will do its full share of work during the life of the chain, without exceeding the limit of safety. Chains for hoisting purposes should be made with short links, so that they will wrap

www.EngineeringEBooksPdf.com

closely around the sheaves or drums without bending. The diameter of the winding drums should be not less than 25 or 30 times the diameter of the iron used for the links. The accompanying table lists the maximum allowable wear for various sizes of chains.

Safe Loads for Ropes and Chains

Safe loads recommended for wire rope or chain slings depend not only upon the strength of the sling but also upon the method of applying it to the load, as shown by the accompanying table giving safe loads as prepared by OSHA. The loads recommended in this table are more conservative than those usually specified, in order to provide ample allowance for some unobserved weakness in the sling, or the possibility of excessive strains due to misjudgment or accident.

[a] These sizes of wrought chain are no longer manufactured in the United States.

Data from *Longshoring Industry*, OSHA Safety and Health Standards Digest, OSHA 2232, 1985.

The working load limit is defined as the maximum load in pounds that should ever be applied to chain, when the chain is new or in "as new" condition, and when the load is uniformly applied in direct tension to a straight length of chain. This limit is also affected by the number of chains used and their configuration. The accompanying table shows the

www.EngineeringEBooksPdf.com

working load limit for various configurations of heat-treated alloy steel chain using a 4 to 1 design factor, which conforms to ISO practice.

Protection from Sharp Corners.—When the load to be lifted has sharp corners or edges, as are often encountered with castings, and with structural steel and other similar objects, pads or wooden protective pieces should be applied at the corners, to prevent the slings from being abraded or otherwise damaged where they come in contact with the load. These precautions are especially important when the slings consist of wire cable or fiber rope, although they should also be used even when slings are made of chain. Wooden corner-pieces are often provided for use in hoisting loads with sharp angles. If pads of burlap or other soft material are used, they should be thick and heavy enough to sustain the pressure, and distribute it over a considerable area, instead of allowing it to be concentrated directly at the edges of the part to be lifted.

[a] Average value is shown. Maximum for nylon rope is 5 per cent higher; tolerance for double braided nylon rope is ± 5 per cent.

[b] Based on tests of new and unused rope of standard construction in accordance with Cordage Institute Standard Test Methods. For double braided nylon rope these values are minimums and are based on a large number of tests by various manufacturers; these values represent results two standard deviations below the mean. The minimum tensile strength is determined by the formula $1057 \times (\text{linear density})^{0.995}$.

[c] These values are for rope in good condition with appropriate splices, in noncritical applications, and under normal service conditions. These values should be reduced where life, limb, or valuable property are involved, or for exceptional service conditions such as shock loads or sustained loads.

Data from Cordage Institute Specifications for nylon rope (three-strand laid and eight-strand plaited, standard construction) and double braided nylon rope.

www.EngineeringEBooksPdf.com

Loads Lifted by Crane Chains.—To find the approximate weight a chain will lift when rove as a tackle, multiply the safe load given in the table *Close-link Hoisting, Sling and Crane Chain* by the number of parts or chains at the movable block, and subtract one-quarter for frictional resistance.

To find the size of chain required for lifting a given weight, divide the weight by the number of chains at the movable block, and add one-third for friction; next find in the column headed "Average Safe Working Load" the corresponding load, and then the corresponding size of chain in the column headed "Size." With the heavy chain or where the chain is unusually long, the weight of the chain itself should also be considered.

Source: The Crosby Group. All dimensions are in inches. Hooks are made of alloy steel, quenched and tempered. For swivel hooks, the data are for a bail of carbon steel. The ultimate load is four times the working load limit (capacity). The swivel hook is a positioning device and is not intended to rotate under load; special load swiveling hooks must be used in such applications.

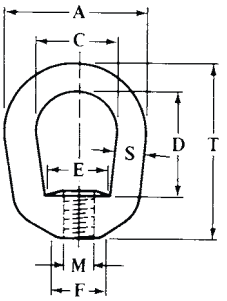
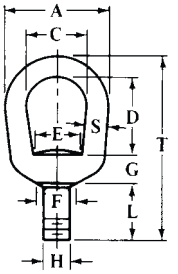
Eye Nuts and Lift Eyes



Eye Nut



Lifting Eye

Eye Nuts

The general function of eye nuts is similar to that of eye-bolts. Eye nuts are utilized for a variety of applications in either the swivel or tapped design.

Specifying Eyebolt Capacities

Rigger's Capacity.—The rigger's capacity refers to the actual load a single eyebolt can lift. The allowable load varies with the angle between the leg of the lifting rig and the shank of the eyebolt. In general, it also assumes that the load to be lifted acts along the axis through the shank. (The primary exception is where the eyebolts are mounted on the sides of the load.) Rigger's capacities are most easily used when the eyebolts are mounted on the top of a uniformly distributed load. In such cases, the total load is divided by the number of eyebolts to be used for the lift in order to determine the required capacity, taking into account the angle of the legs of the rig. Fig. 1 shows such an application.

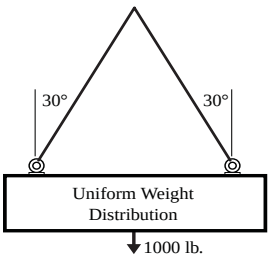

Fig. 1. Uniformly Distributed Load, Equal Tension in Legs of the Lifting Rig

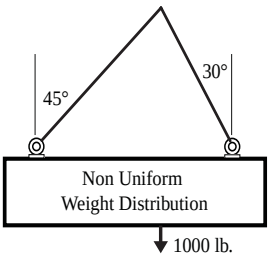

Fig. 2. Nonuniform Weight Distribution, Unequal Tension in Legs of the Lifting Rig

Example: By symmetry in Fig. 1, if the load is 1000 pounds, each eyebolt carries one-half of the 1000 pound total load, i.e., 500 lb. in a vertical direction. Therefore, each eyebolt must have a rigger's capacity of at least 500 lb. for a sling angle of 30 °.

Engineering Capacity.—The engineering capacity, on the other hand, refers to the allowable tension in the leg of the lifting rig as it is applied to the eyebolt. This type of capacity is particularly useful when the load distribution is nonuniform, requiring nonsymmetrical slings, or when the eyebolts are not placed on the top surface of the load. In such cases, the load to be lifted does not act through the shank of the eyebolt. It is necessary to determine the tension in each leg of the rig before sizing the eyebolts. *Caution: Dividing the total load by the number of eyebolts may give erroneous and unsafe results.* Fig. 2 shows such an application.

Example: In Fig. 2, the tension in the left and right cables are T_1 and T_2, respectively, the horizontal tension components acting on the eyebolts are equal, as follows:

$$T_1 \sin 45 = T_2 \sin 30$$

$$T_1 = T_2 \frac{\sin 30}{\sin 45} \qquad (1)$$

From Fig. 2, the vertical force components supporting the weight are

$$T_1 \cos 45 + T_2 \cos 30 = 1000 \qquad (2)$$

Substituting T_1 from Equation (1) into (2), then solving yields $T_2 = 732.1$ and $T_1 = 517.6$.

Step 1:

$$T_2 \frac{\sin 30}{\sin 45} \cos 45 + T_2 \cos 30 = T_2\left(\frac{\sin 30}{\tan 45} + \cos 30\right) = 1000$$

$$T_2 = \left(\frac{1000}{1.366}\right) = 732.1$$

Step 2:

$$T_1 = \frac{1000 - T_2 \cos 30}{\cos 45}$$

$$T_1 = 517.6$$

The left eyebolt requires an engineering capacity of at least 518 lb for an angle of 45°, while the right eyebolt requires a capacity of at least 732 lb for an angle of 30 °.

Rope Splicing

Splicing is the operation when two pieces of rope are joined by unlaying the strands and weaving or intertwining the strands of one end with those of the other.

Short Splice.—The first step in making a short splice is to unlay or untwist the strands at the end of each rope. After the ropes are placed together, as shown at *A,* Fig. 1a, the strands on one side, as shown at *d*, *e*, and *f*, are either held together by the left hand or are fastened together with twine, in case the rope is too large to be held by the hand. The splicing operation is started by taking one of the strands as at *a*, and passing it across or over the adjacent strand *d* and then under the next strand *e*, after having made an opening beneath strand e. The strands *b* and *c* are next treated in the same manner, first one and then the other being passed over its adjoining strand and then under the next successive one. These same operations are then repeated for the strands *d*, *e* and *f* of the other rope. The splice will now appear as shown at *B,* Fig. 1b. In order to make it stronger and more secure, the projecting strands of each rope are again passed diagonally over the adjoining strands and under the next successive ones. The splice should then be subjected to a strong pull, in order to tighten the strands and make them more compact. The projecting ends of the strands should then be cut off, thus completing the splice as shown at *C*. For making the openings beneath the strands on the rope, what is known as a marlin spike is generally used. This is merely a tapering, pointed pin made of wood or iron.

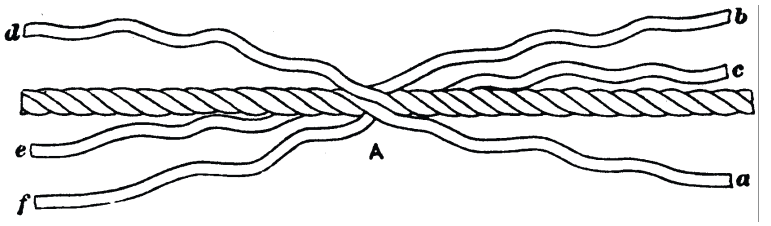

Fig. 1a. Method of Making a Short Splice

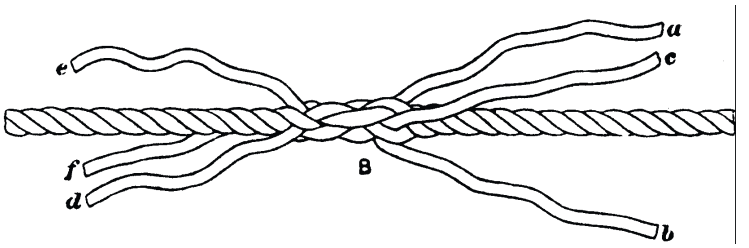

Fig. 1b. Method of Making a Short Splice

Fig. 1c. Method of Making a Short Splice

Long Splice.—When a rope has to pass through pulley blocks, or in case any increase in the size of the rope would be objectionable, the short splice is not suitable and the long splice should be employed. The diameter of a long splice is the same as that of the rope and, if the work is done carefully, the place where the ends are joined can scarcely be distinguished from the rest of the rope. The ends of each rope are first unlaid or untwisted the same as when making a short splice, but for a distance about three times as long. These ends are then placed together so that each strand lies between two strands of the other rope, the same as for a short splice. One of the strands is next unlaid and then a strand from the other rope is curled around into the groove thus made, as indicated at *A* Fig. 2a, strand a having been unlaid and strand *b* from the other rope end, put into its place. Care should be taken to twist strand *b* so that it will lie in its natural position into the groove previously occupied by strand *a*, as the neatness of the splice will depend partly upon the care with

www.EngineeringEBooksPdf.com

which this part of the work is done. This operation is then repeated in connection with strands *c* and *d*, strand *c* being unlaid and strand *d* twisted around to occupy the groove thus made. The splice will now be as shown at *B*, Fig. 2b, and the next step is that of disposing of the protruding ends of the strands. After these strands have been cut to about the length shown at *B*, two of the strands, as at *a* and *b*, are first reduced in size by removing about one-third of the fiber; these ends are then tied by an overhand knot as shown at e. After tightening this knot, the protruding ends may be disposed of the same as when making a short splice, or by passing them over the adjoining strand and through the rope, under the next one. By gradually removing the fiber each time the end is passed across an adjoining strand, the enlargement of the rope at this point may be made very slight and scarcely noticeable. The strands *f* and *g* which remain in their original positions in the center of the splice, and the strands *c* and *d* are disposed of in a similar manner, thus completing the splice as shown at Fig. 2c.

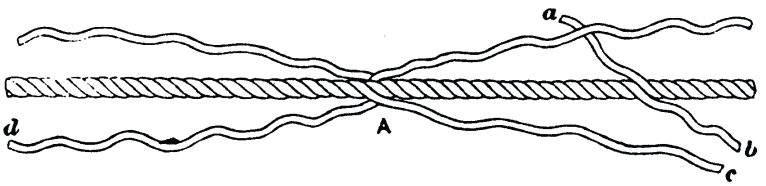

Fig. 2a. How a Long Splice is Made

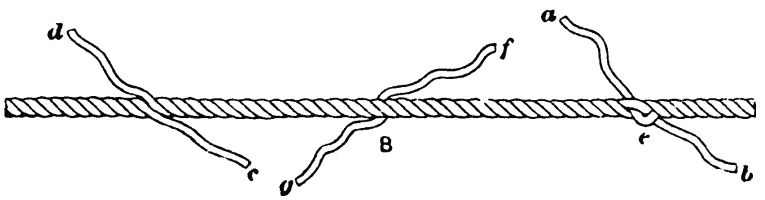

Fig. 2b. How a Long Splice is Made

Fig. 2c. How a Long Splice is Made

Eye-Splice.—When a loop is formed at the end of a rope by splicing the free end to the main or standing part of the rope, this is known as an *eye-splice.* The end of the rope is first unlaid about as far as it would be for making a short splice. After bending the end around to form a loop of the required size, the middle strand a, Fig. 3a, is tucked under a strand on the main part of the rope. The strand *b* is next inserted from the rear side under the strand on the main part which is just above the strand under which a was inserted. Since strand *b* is pushed under the strand on the main part from the rear side, it will come out at the point where strand *a* went in, as Fig. 3b. The third strand *c* is now passed over the strand under which strand a was inserted, and then under the next successive one, as Fig. 3c. These three strands are next pulled taut and then about one-third of the fiber should be cut from them; they are next tucked away by passing a strand over its adjoining one and under the next successive strand. Cutting away part of the fiber or yarns is to reduce the size of the splice and give it a neater appearance. By gradually thinning out the fiber, the over-lapping strands may be given a gradual taper, as Fig. 3d which shows the completed eye-splice.

Method of Making an Eye-splice.— : When a loop is formed at the end of a rope by splicing the free end to the main or standing part of the rope, this is known as an *eye-splice.* The end of the rope is first unlaid about as far as it would be for making a short splice. After bending the end around to form a loop of the required size, the middle strand *a*, Fig. 3a, is tucked under a strand on the main part of the rope. The strand *b* is next inserted from the rear side under the strand on the main part which is just above the strand under which *a* was inserted. Since strand *b* is pushed under the strand on the main part from the rear side, it will come out at the point where strand *a* went in, as Fig. 3b. The third strand *c* is now passed

Govenors

Engine Governors.—Governors may be of a purely centrifugal type such as the fly-ball or pendulum design previously referred to, or the principle of inertia may be introduced to secure better speed regulation. Thus, there are two general classes of governors known as centrifugal and inertia governors. The method of utilizing the motion of the governing element for regulating the speed varies; as applied to steam engines, there is the general type of governor which controls the speed by operating a throttling valve which increases or diminishes the amount of steam admitted to the steam-chest, and another general type which regulates the speed by changing the point of cut-off and consequently the amount of expansion in the cylinders.

In the design of governors, the sensitiveness, effort, and stability of the governor are important factors. The sensitiveness of a fly-ball governor is indicated by the amount that the governing sleeve is displaced for a given change in speed, the displacement being relatively large for a given speed change if the governor is sensitive.

The term “effort” as applied to a governor relates to the energy it is capable of exerting upon the governing mechanism. Thus, in the case of a fly-ball governor, the effort indicates the energy exerted on the sleeve while the governor speed is increasing or diminishing. If the energy stored in a revolving governor is small, its sensitiveness will be reduced, because a larger speed change is necessary to obtain the power for operating the governing mechanism than would be required with a governor which exerts greater energy for a given speed change.

When a governor occupies a definite position of equilibrium for any speed within the range of speeds controlled by the governor, it is said to be “stable.” If the load on an engine having a fly-ball governor is diminished, the balls of a stable governor will move outward to a new position as the speed increases, although there will usually be a temporary oscillating movement on each side of this new position, the oscillations gradually diminishing. If the governor were instable (and therefore useless) the oscillations would increase until the limiting points were reached.

www.EngineeringEBooksPdf.com

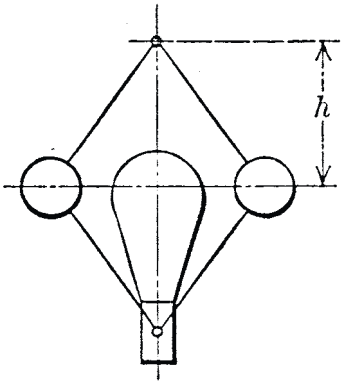

Fig. 1.

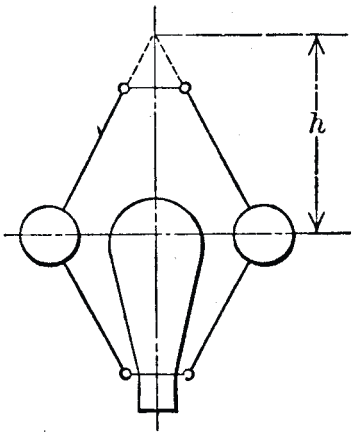

Fig. 2.

Loaded or Weighted Fly-ball Governors.—As the arms of a governor of the conical pendulum type swing outward toward the horizontal position as the result of increasing speed, the change in height h (see Fig. 1) is small for given changes in speed. For instance, if the speed is changed from 50 to 70 revolutions per minute, the difference between the values of h is nearly 7 inches, whereas if the speed changes from 200 to 300 revolutions per minute, the difference in height h for the two speeds is only about ½ inch. Hence, the simple pendulum governor is not suitable for the higher speeds, because then the movement which accompanies the speed changes is too small to secure proper regulation through the governing mechanism. Fly-ball governors are adapted for much higher speeds by loading them. The load may be in the form of a weight which surrounds the spindle, as illustrated by Fig. 1. This is known as a Porter governor.

In the following formula, w = the weight of one governor ball in pounds; c = the weight of the additional load; h = the height in feet indicated by the diagram, Fig. 1; n = speed of governor in revolutions per minute:

$$h = \frac{2933}{n^2} \times \frac{e + w}{w}$$

If the governor is constructed as indicated by the diagram Fig. 2, the height h is not measured from the points at which the arms or rods are suspended, but from the point where the axes of the rods intersect with the vertical center line. The outward movement of the balls may be resisted by a spring instead of a weight, as in the case of the Hartnell governor, which is known as a spring-loaded type.

Sensitiveness and Stability of Governors.—The sensitiveness of one governor may be compared with that of another by determining the *coefficient of speed variations.* If C = the coefficient of speed variations, M = maximum speed within limits of the governor action; M_1 = minimum speed within limits of governor action; m = mean speed within these limits; then,

$$C = \frac{M - M_1}{m}$$

The minimum value of coefficient C necessary to obtain stability in a pendulum type of governor is given by the following formula in which y = distance the fly-balls move horizontally in feet; F = mean centrifugal force of fly-balls in pounds; H = indicated horsepower of engine; W = the weight of engine flywheel in pounds; S = revolutions per minute of main shaft; R = the flywheel radius in feet.

www.EngineeringEBooksPdf.com

$$C = 4000 \sqrt[3]{\frac{xy}{F}} \times \sqrt[8]{\frac{H^2}{S^4 R^4 W^2}}$$

The factor x in this formula represents that weight which would be equivalent to the weights of the various moving parts, if it were centered at a point corresponding to the center of gravity of the fly-balls. To determine the value of x, first determine the weights of the different moving parts of the governor, such as the balls, the central weight or load (in the case of a Porter governor), the sleeve, etc.; multiply the weight of each part by the square of the distance it moves from one position to the other; add the various products thus obtained, and divide the total sum by the square of the corresponding movement of the fly-balls at right angles to the governor spindle.

Shaft Governors.—Shaft governors are so named because the governing mechanism is carried by the main shaft and is commonly attached in some way to the flywheel. One type is so arranged that, in the case of a steam engine, the action of centrifugal force on a pivoted and weighted lever, to which a spring is attached, changes the position of the eccentric which operates the slide valve, thus increasing or decreasing the valve travel and changing the point of cut-off. Another type is so designed that the inertia of a pivoted "weight arm" accelerates the governing action by acting in conjunction with the effect of centrifugal force, thus increasing the sensitiveness of the governor. With the inertia governor, the effort or force needed to actuate the governing mechanism increases as the rate of velocity change increases; hence this type is adapted to engines liable to sudden load changes. When the load remains practically constant, the centrifugal type of shaft governor is often employed in preference to the inertia type. The design of these governors depends upon the arrangement of the governing mechanism and upon varying factors.

Machinery Noise

Noise from machinery or mechanical systems can be controlled to some degree in the design or development stage if quantified noise criteria are provided the designer. Manufacturers and consumers may also use the same information in deciding whether the noise generated by a machine will be acceptable for a specific purpose.

Noise criteria for may be classified as follows: 1) relating to the degree of interference with speech communications; 2) relating to physiological damage to humans, especially hearing; and 3) those relating to psychological disturbances in people exposed to noise.

Sound Level Specifications.—Noise criteria generally are specified in some system of units representing sound levels. One commonly used system specifies sound levels in units called decibels on the "A" scale, written dBA. The dBA scale designates a sound level system weighted to match human hearing responses to various frequencies and loudness. For example, to permit effective speech communication, typical criteria for indoor maximum noise levels are: meeting and conference rooms, 42 dBA; private offices and small meeting rooms, 38 to 47 dBA; supervisors' offices and reception rooms, 38 to 52 dBA; large offices and cafeterias, 42 to 52 dBA; laboratories, drafting rooms, and general office areas, 47 to 56 dBA; maintenance shops, computer rooms, and washrooms, 52 to 61 dBA; control and electrical equipment rooms, 56 to 66 dBA; and manufacturing areas and foremen's offices, 66 dBA. Similarly, there are standards and recommendations for daily permissible times of exposure at various steady sound levels to avoid hearing damage. For a working shift of 8 hours, a steady sound level of 90 dBA is the maximum generally permitted, with marked reduction in allowable exposure times for higher sound levels.*

Measuring Machinery Noise.—The noise level produced by a single machine can be measured by using a standard sound level meter of the handheld type set to the dBA scale.

* After April 1983, if employee noise exposures equal or exceed an 8-hour, time-weighted average sound level of 85 dB, OSHA requires employers to administer an effective hearing conservation program.

www.EngineeringEBooksPdf.com

However, when other machines are running at the same time, or when there are other background noises, the noise of the machine cannot be measured directly. In such cases, two measurements, taken as follows, can be used to calculate the noise level of the individual machine. The meter should be held at arm's length and well away from any bystanders to avoid possible significant error up to 5 dBA.

Step 1. At the point of interest, measure the total noise, T, in decibels; that is, measure the noise of the shop and the machine in question when all machines are running; Step 2. Turn off the machine in question and measure B, the remaining background noise level; Step 3. Calculate M, the noise of the machine alone.

$$M = 10\log\left(10^{\frac{T}{10}} - 10^{\frac{B}{10}}\right)$$

Example 1: With a machine running, the sound level meter reads 51 decibels as the total shop noise T; and with the machine shut off the meter reads 49 decibels as the remaining background noise B. What is the noise level M of the machine alone?

$$M = 10\log\left(10^{\frac{51}{10}} - 10^{\frac{49}{10}}\right) = 46.7 \text{ decibels dBA}$$

Example 2: If in Example 1 the remaining background noise level B was 41 decibels instead of 49, what is the noise level of the machine alone?

$$M = 10\log\left(10^{\frac{51}{10}} - 10^{\frac{41}{10}}\right) = 50.5 \text{ decibels dBA}$$

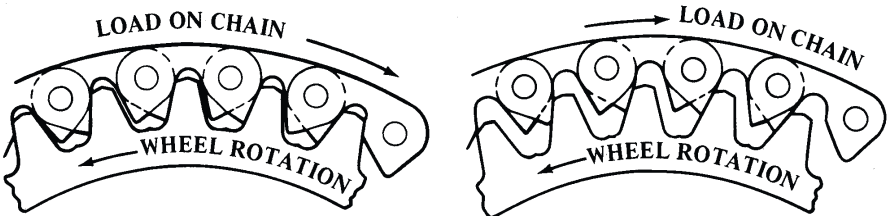
Note: From this example it is evident that when the background noise level B is approximately 10 or more decibels lower than the total noise level T measured at the machine in question, then the background noise does not contribute significantly to the sound level at the machine and, for practical purposes, $M = T$ and no calculation is required.

www.EngineeringEBooksPdf.com

Silent or Inverted Tooth Chain

Silent or inverted tooth chain consists of a series of toothed links alternately assembled either with pins or with a combination of joint components in such a way that the joints articulate between adjoining pitches. Side Guide chain has guide links which straddle the sprocket sides to control the chain laterally. Center Guide chain has guide links that run within a circumferential groove or grooves for lateral control.

Characteristics of Silent Chain Drives.—The silent or "inverted-tooth" driving chain has the following characteristics: The chain passes over the face of the wheel like a belt and the wheel teeth do not project through it; the chain engages the wheel by means of teeth extending across the full width of the under side, with the exception of those chains having a central guide link; the chain teeth and wheel teeth are of such a shape that as the chain pitch increases through wear at the joints, the chain shifts outward upon the teeth, thus engaging the wheel on a pitch circle of increasing diameter; the result of this action is that the pitch of the wheel teeth increases at the same rate as the chain pitch. The accompanying illustration shows an unworn chain to the left, and a worn chain to the right, which has moved outward as the result of wear. Another distinguishing feature of the silent chain is that the power is transmitted by and to all the teeth in the arc of contact, irrespective of the increasing pitch due to elongation. The links have no sliding action either on or off the teeth, which results in a smooth and practically noiseless action, the chain being originally designed for the transmission of power at higher speeds than are suitable for roller chains. The efficiency of the silent chain itself may be as high as 99 per cent, and for the complete drive, from 96 to 97 percent, under favorable conditions; from 94 to 96 per cent can be secured with well-designed drives under average conditions.



The life and upkeep of silent chains depend largely upon the design of the entire drive, including the provision for adjustment. If there is much slack, the whipping of the chain will greatly increase the wear, and means of adjustment may double the life of the chain. A slight amount of play is necessary for satisfactory operation. The minimum amount of sag should be about $\frac{1}{8}$ inch. Although the silent chain shifts outward from the teeth and adjusts itself for an increase of pitch, it cannot take up the increased pitch in that portion of the chain between the wheels; therefore, the wheel must lag to the extent of the increased pitch in the straight portion of the chain.

Standard Silent Chain Designation.—The standard chain number or designation for $\frac{3}{8}$-inch pitch or larger consists of:

1) a two letter symbol SC; 2) one or two numerical digits indicating the pitch in eighths of an inch; and 3) two or three numerical digits indicating the chain width in quarter-inches.

Thus, SC302 designates a silent chain of $\frac{3}{8}$-inch pitch and $\frac{1}{2}$-inch width, while SC1012 designates a silent chain of $1\frac{1}{4}$-inch pitch and 3-inch width.

The standard chain number or designation for $\frac{3}{16}$-inch pitch consists of:

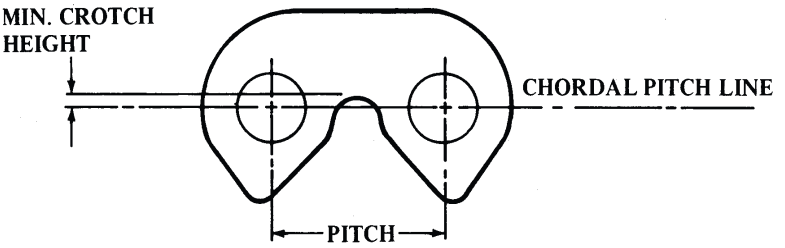
a) a two letter symbol SC; b) a zero followed by a numerical digit indicating pitch in sixteenths of an inch; and c) two numerical digits indicating the chain width in thirty-seconds of an inch. Thus, SC0309 designates a silent chain of $\frac{3}{16}$-inch pitch and $\frac{9}{32}$-inch width.

Silent Chain Links.—The joint components and link contours vary with each manufacturer's design. As shown in Table 1 minimum crotch height and pitch have been standard-

www.EngineeringEBooksPdf.com

ized for interchangeability. Chain link designations for 3/8-inch and larger pitch are given in Table 1

Table 1. American National Standard Silent Chain Links*



Min.Crotch Height = 0.062 ×Chain Pitch.

Link contour may vary but must engage standard sprocket tooth so that joint centers lie on pitch diameter of sprockets.

Chain Number	Chain Pitch		Stamp	Crotch Height, Min.	
	inch	mm		inch	mm
SC3 (Width in 1/4 in.)	0.375	9.52	SC3 or 3	0.0232	0.589
SC4 (Width in 1/4 in.)	0.500	12.70	SC4 or 4	0.0310	0.787
SC5 (Width in 1/4 in.)	0.625	15.88	SC5 or 5	0.0388	0.985
SC6 (Width in 1/4 in.)	0.750	19.05	SC6 or 6	0.0465	1.181
SC8 (Width in 1/4 in.)	1.000	25.40	SC8 or 8	0.0620	1.574
SC10 (Width in 1/4 in.)	1.250	31.76	SC10 or 10	0.0775	1.968
SC12 (Width in 1/4 in.)	1.500	38.10	SC12 or 12	0.0930	2.302
SC16 (Width in 1/4 in.)	2.000	50.80	SC16 or 16	0.1240	3.149

Silent Chain Sprocket Diameters.—The important sprocket diameters are:

1) outside diameter; 2) pitch diameter; 3) maximum guide groove diameter; and

4) over-pin diameter.

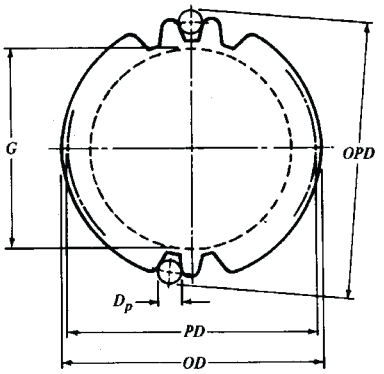
These are shown in the diagram in Table 2 and the symbols and formulas for each are also given in this table. Table 3a gives values of outside diameters for sprockets with rounded teeth and with square teeth, pitch diameters, and over-pin diameters for chains of 1-inch pitch and sprockets of various tooth numbers. Values for chains of other pitches (3/8 inch and larger) are found by multiplying the values shown by the pitch. Table 3b gives this information for 3/16- in. pitch chains. Note that the over-pin diameter is measured over gage pins having a diameter D_p=0.625P in. for 3/8-in. and larger pitch and D_p=0.667P in. for 3/16-in. pitch chains. Over-pin diameter tolerances are given in Table 4a and 4b.

Silent Chain Sprocket Profiles and Chain Widths.—Sprocket tooth face profiles for side guide chain, center guide chain and double guide chain are shown in Table 4c and 4d together with important dimensions for chains of various pitches and widths. Maximum over-all width M of the three types of chain are also given in this table for various pitches and widths. It should be noted that the sprocket tooth width W for the side guide chain is given in Table 5 for one-half-inch wide chains of 3/8-inch and 1/2-inch pitches. No values of W for other chain sizes are specified in American National Standard B29.2M-1982 (1987).

* For 3/8-inch and larger pitch chains.

www.EngineeringEBooksPdf.com

Table 2. ANSI Silent Chain Sprocket Diameters *(ANSI B29.2M-1982, R1987)*



P = Chain Pitch
PD = Pitch Diameter
OD = Outside Diameter

[a] For tolerances on over-pin diameters, see table 4.

[b] Blank diameters are 0.020 inch larger and maximum guide groove diameters G are 1.240 inches smaller than these outside diameters.

[c] These diameters are maximum; tolerance is +0,–0.50× pitch, inches.

Tolerance for maximum eccentricity (total indicator reading) of pitch diameter with respect to bore is 0.001 × PD, but not less than 0.006 nor more than 0.032 inch.

[a] For tolerances on over-pin diameters, see table 4.

[b] Blank diameters are 0.020 inch larger and maximum guide groove diameters G are 1.240 inches smaller than these outside diameters.

[c] These diameters are maximum; tolerance is +0,–0.50 × pitch, inches.

Tolerance for maximum eccentricity (total indicator reading) of pitch diameter with respect to bore is 0.004 in. up to and including 4 in. diameter; and 0.008 in., over 4 in. diameter.

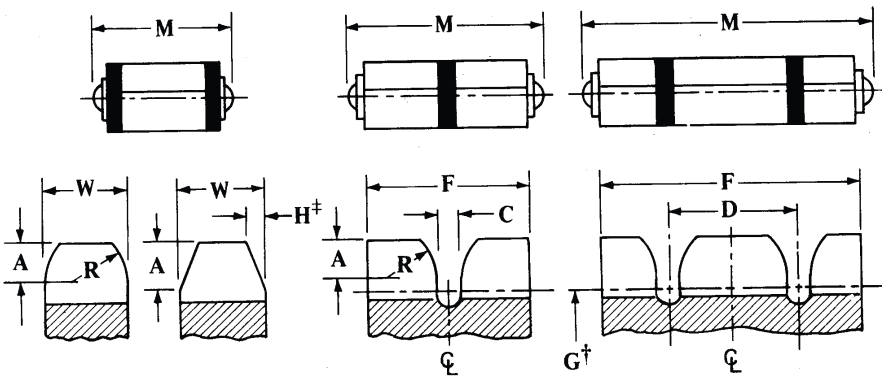
[a] All tolerances are negative.



Grooving tool may be either square or round end but groove must be full width down to diameter of *G*. For values of *G* (max.) see footnote to Table 3a

Values of H (± 0.003 in.) = 0.051 in. are given only for chain numbers SC302 and SC402. M = Max. overall width of chain. The maximum radius over a new chain engaged on a sprocket will not exceed the sprocket pitch radius plus 75 per cent of the chain pitch. To obtain the chain widths and sprocket face dimensions in millimeters, multiply each entry by 25.4.

SC0329			0.966			0.896		…
SC0331			1.028			0.959		…

All dimensions in inches. M = Max. overall width of chain.

To obtain chain width and sprocket face dimensions in millimeters, multiply each entry by 25.4.

Sprocket Hub Dimensions.—The important hub dimensions are the outside diameter, the bore, and the length. The maximum hub diameter is limited by the need to clear the chain guides and is of particular importance for sprockets with low numbers of teeth. The American National Standard for inverted tooth chains and sprocket teeth ANSI B29.2M-1982 (R1987) provides the following formulas for calculating maximum hub diameters, *MHD*.

$$MHD(\text{for hobbed teeth}) = P\left[\cot\left(\frac{180^\circ}{N}\right) - 1.33\right]$$

$$MHD(\text{for stradle cut teeth}) = P\left[\cot\left(\frac{180^\circ}{N}\right) - 1.25\right]$$

www.EngineeringEBooksPdf.com

Maximum hub diameters for sprockets with from 17 to 31 teeth are given in Table 5. Maximum hub diameters for other methods of cutting teeth may differ from these values. Recommended maximum bores are given in Table 6.

Table 5. American National Standard Minimum Hub Diameters for Silent chain Sprockets (17 to 31 Teeth) *ANSI B29.2M-1982,1987*

No. Teeth	Hob Cut	Straddle Cut	No. Teeth	Hob Cut	Straddle Cut	No. Teeth	Hob Cut	Straddle Cut
	Min. Hub Diam.			Min. Hub Diam.			Min. Hub Diam.	
17	4.019	4.099	22	5.626	5.706	27	7.226	7.306
18	4.341	4.421	23	5.946	6.026	28	7.546	7.626
19	4.662	4.742	24	6.265	6.345	29	7.865	7.945
20	4.983	5.063	25	6.586	6.666	30	8.185	8.265
21	5.304	5.384	26	6.905	6.985	31	8.503	8.583

All dimensions in inches.

Values shown are 1-inch pitch chain. For other pitches (⅜- inch and larger) multiply the values given by the pitch.

Good practice indicates that teeth of sprockets up to and including 31 teeth should have a Rockwell hardness of *C*50 min.

Table 6. Recommended Maximum Sprocket Bores for Silent Chains

Number of Teeth	Chain Pitch, Inches							
	⅜	½	⅝	¾	1	1¼	1½	2

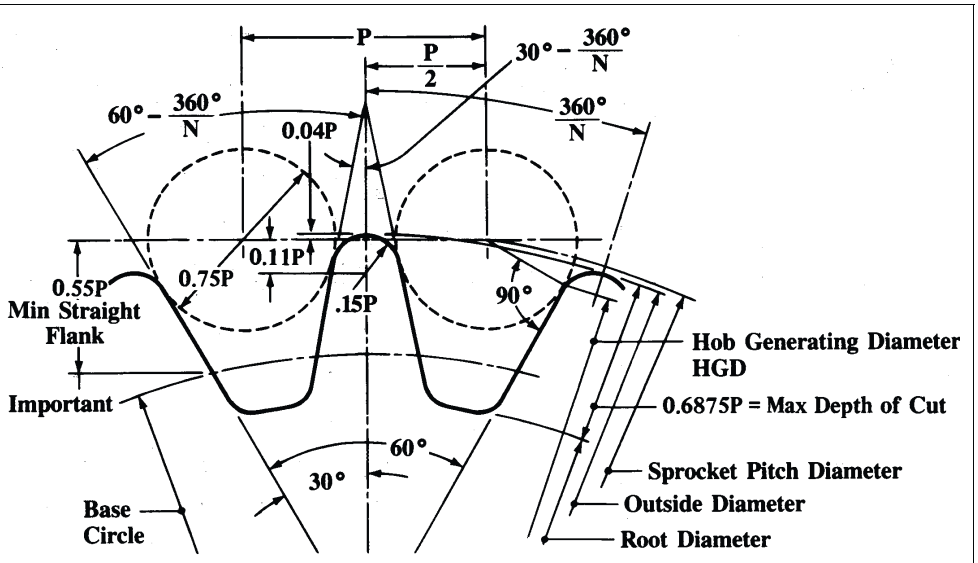
Table 9. Hobs for ANSI ⅜- inch and larger Silent Tooth Sprocket*



P = Chain Pitch

N = Number of Teeth

$$HGD = P\sqrt{\frac{1}{\sin\frac{180°^2}{N}} + 0.5625 - \frac{1.5\sin\left(30 - \frac{180}{N}\right)^\circ}{\sin\frac{180°}{N}}}$$

Sprocket Design and Tooth Form.—Except for tooth form, silent chain sprocket design parallels the general design practice of roller chain sprockets as covered in the previous section.

As shown in Tables 7a and 7b, sprockets for American National Standard silent chains have teeth with straight-line working faces. The tops of teeth for ⅜-in. and larger pitch chains may be rounded or square. Bottom clearance below the working face is not specified but must be sufficient to clear the chain teeth. The standard tooth form for ⅜-in. and larger pitch chains is designed to mesh with link plate contours having an included angle of 60 degrees as shown in the diagram of Table 7a. The standard tooth form for 3/16-in. pitch chains has an included angle of 70 degrees as shown in Table 7b. It will be seen from these tables that the angle between the faces of a given tooth [60°–720°/N for ⅜-in. pitch and larger; 70°–720°/N for 3/16-in. pitch] becomes smaller as the number of teeth decreases. Therefore, for a ⅜-in. pitch or larger 12-tooth sprocket it will be zero. In other words the tooth faces will be parallel.

For smaller tooth numbers the teeth would be undercut. For best results, 21 or more teeth are recommended; less than 17 should not be used.

Cutting Silent Chain Sprocket Teeth.—Sprocket teeth may be cut by either a straddle cutter or a hob. Essential dimensions for straddle cutters are given in Table 8 and for hobs in Table 9 and 10. American National Standard silent chain hobs are stamped for identification as shown in Fig. 1 on page 3471.

Design of Silent Chain Drives.—The design of silent chain transmissions must be based not only upon the power to be transmitted and the ratio between driving and driven shafts, but also upon such factors as the speed of the faster running shaft, the available space, assuming that it affects the sprocket diameters, the character of the load and certain other factors. Determining the pitch of the chain and the number of teeth on the smallest sprocket are the important initial steps. Usually any one of several combinations of pitches and sprocket sizes may be employed for a given installation. In attempting to select the best combination, it is advisable to consult with the manufacturer of the chain to be used. Some of the more important fundamental points governing the design of silent chain transmissions will be summarized.

The design of a silent chain drive consists, primarily, of the selection of the chain size, sprockets, determination of chain length, center distance, lubrication method, and arrangement of casings.

Pitch of Silent Chain.—The pitch is selected with reference to the speed of the faster running shaft which ordinarily is the driver and holds the smaller sprocket. The following pitches are recommended: for a faster running shaft of 2000 to 5000 rpm, $\frac{3}{8}$-inch pitch; for 1500 to 2000 rpm, $\frac{1}{2}$-inch pitch; for 1200 to 1500 rpm, $\frac{5}{8}$-inch pitch, for 1000 to 1200 rpm, $\frac{3}{4}$-inch pitch; for 800 to 1000 rpm, 1-inch pitch; for 650 to 800 rpm, $1\frac{1}{4}$-inch pitch; for 300 to 600 rpm, $1\frac{1}{2}$-inch pitch; for 300 to 500 rpm, 2-inch pitch; and for below 300 rpm, $2\frac{1}{2}$-inch pitch. As the normal operating speeds increase, the allowable pitch decreases. Recommendations relating to the relationship between pitch and operating speed are intended for normal or average conditions. Speeds for a given pitch may be exceeded under favorable conditions and may have to be reduced when conditions are unfavorable. In general, smoother or quieter operation will result from using the smallest pitch suitable for a given speed and load. However, a larger pitch which might be applicable under the same conditions, will result in a narrower chain and a less expensive transmission. This relationship usually is true when there is a small speed reduction and comparatively long center distance. If there is a large speed reduction and short center distance, drives having the smaller pitches may be less expensive.

Maximum Ratios for Silent Chain Drives.—The maximum permissible ratios between driving and driven sprockets vary somewhat for different conditions and usually range from 6- or 7-to-1 up to 10-to-1. Some drives have even higher ratios, especially when the operating conditions are exceptionally favorable. When a large speed reduction is necessary, it is preferable as a general rule to use a double reduction or compound type of transmission instead of obtaining the entire reduction with two sprockets. Drives should be so proportioned that the angle between the two strands of a tight chain does not exceed 45 degrees. When the angle is larger, the chain does not have sufficient contact with the driving sprocket.

Sprocket Size and Chain Speed: A driving sprocket with not less than 17 teeth is generally recommended. For the driven sprocket, one manufacturer recommends 127 teeth as a maximum limit and less than 100 as preferable. If practicable, the sprocket sizes should be small enough to limit the chain speed to from 1200 to 1400 feet per minute. If the chain speed exceeds these figures, this may indicate that the pitch is too large or that a smaller pitch, and, consequently, a reduction in sprocket diameters (and chain speed) will result in better operating conditions. Both sprockets should preferably have a “hunting tooth ratio” relative to the number of chain links for uniform wear. See *Hunting Tooth Gear Ratios*, page 3350.

If there is a small reduction in speed between the driving and driven shafts, both sprockets may be made as small as is consistent with satisfactory operation, either to obtain a compact drive or possibly to avoid excessive chain speed in cases where the rotative speed is high for a given horsepower. Under such conditions, one manufacturer recommends driving sprockets ranging from 17 to 30 teeth, and driven sprockets ranging from 19 to 33

www.EngineeringEBooksPdf.com

teeth. If the number of revolutions per minute is low for a given horsepower and the center distance comparatively long, then the recommended range for driving sprockets is from 23 to 111 teeth, and driven sprockets from 27 to 129 teeth. The preferable range is from 17 to 75 teeth for the driving sprockets, and 19 to 102 teeth for the driven sprockets.

Center Distance for Silent Chain Drives.—If the ratio of the drive is small, it is possible to locate the sprockets so close-that the teeth just clear; however, as a general rule, the minimum center-to-center distance should equal the sum of the diameters of both sprockets. According to the Whitney Chain & Mfg. Co., if the speed ratio is not over 2½-to-1, the center distance may be equal to one-half the sum of the sprocket diameters plus tooth clearance, providing this distance is not less than the minimum given in Table 11. If the speed ratio is greater than 2½-to-1, the center distance should not be less than the sum of the sprocket diameters.

Table 11. Minimum Center Distances for Various Pitches

Pitch, inches	⅜	½	⅝	¾	1	1¼	1½
Minimum Center Distances, inches	6	9	12	15	21	27	33

When the chain length in pitches is known, the equivalent center distance for a tight chain may be determined by the formula for roller chain found on page 2553.

In selecting chain length, factors determining length should be adjusted so that the use of offset links may be avoided wherever possible. Chain lengths of an uneven number of pitches are also to be avoided.

Silent Tooth Chain Horsepower Capacity.—The horsepower ratings given in Tables 12a, 12b, and 12c have been established on a life expectancy of approximately 15,000 hours under optimum drive conditions, i.e. for a uniform rate of work where there is relatively little shock or load variation throughout a single revolution of a driven sprocket. Using these horsepower ratings as a basis, engineering judgment should be exercised as to the severity of the operating conditions for the intended installation, taking into consideration the source of power, the nature of the load, and the resulting effects of inertia, strain, and shock. Thus, for other than optimum drive conditions, the specified horsepower must be multiplied by the applicable service factor to obtain a "design" horsepower value. This is the value used to enter Table 13 to obtain the required size of chain.

Service Factors: For a uniform type of load, a service factor of t.o for a to-hour day and 1.3 for a 24-hour day are recommended. For a moderate shock load, service factors of 1.4 for a 10-hour day and 1.7 for a 24-hour day are recommended. For heavy shock loads, service factors of 1.7 for a 10-hour day and 2.0 for a 24-hour day are recommended. For extensive table of service factor applications, see supplementary information in ANSI B29.2M-1982.

Installation of Silent Chain Drives.—In installing chain transmissions of any kind, horizontal drives are those having driving and driven shafts in a horizontal plane. These are always preferable to vertical drives, which have a vertical center line intersecting the driving and driven shafts. If one sprocket must be higher than the other, avoid a vertical drive if possible by so locating the two sprockets that the common center line inclines from the vertical as far as is permitted by other conditions which might govern the installation. If practicable, an adjustment should be provided for the center distance between the driving and driven shafts.

Slack Side of Chain: As a general rule, the slack strand of a chain should be on the lower side of a horizontal drive. If the drive is not horizontal but angular or at some angle less than 90 degrees from the vertical, the slack should preferably be on that side which causes the strand to curve outward or away from the center line of the driving and driven shafts. Whenever the slack strand is on the upper side of either a horizontal or inclined drive,

www.EngineeringEBooksPdf.com

adjustment for the center distance is especially important to compensate for possible chain elongation.

Lubrication: The life of a silent chain subjected to conditions such as are common to automobile drives, depends largely upon the wear of the joints. On account of the high speed and whipping action, it is important to have the chains well oiled. When splash lubrication is employed, the supply pipe should be placed so that the oil will be directed against the inside of the chain. It is preferable that silent chains be operated in an oil-retaining casing with provisions for lubrication. Avoid using greases of any kind. The viscosity of the oil depends on temperature, as follows:

Ambient Temp. °F	Chain Pitch		Ambient Temp. °F	Chain Pitch	
	3/16 & 3/8 inch	1/2 inch & larger		3/16 & 3/8 inch	1/2 inch & larger
	Recommended Lubricant			Recommended Lubricant	
20-40	SAE 10	SAE 20	100-120	SAE 30	SAE 40
40-100	SAE 20	SAE 30	120-140	SAE 40	SAE 50

Double-Flexure Silent Chain.—In double-flexure chain, the teeth of the link plates project on both sides of the chain and the chain flexes in both directions. This chain is used where the drive arrangements require that sprockets contact both sides of the chain. Neither double-flexure chain nor sprockets are covered in American National Standard ANSI 29.2M-1982 (R1987).

Horsepower Ratings Per Inch of Chain Width for Silent Chain Drives — 1982.—

The following industrial standard horsepower ratings for silent chain drives have been supplied by the American Chain Association. These ratings are for American National Standard silent chain as covered by ANSI B29.2M-1982 (R1987). These values may require modification by using the appropriate service factors (see *Service Factors*, page 3475). These factors, which apply to typical drives, are intended as a general guide only, and engineering judgment and experience may indicate different modifications to suit the nature of the load.

$$\text{Horsepower capacity of chain per inch of width} = \frac{\text{Rating in Table 13a, 13b, 13c}}{\text{Service Factor}}$$

$$\text{Chain width for given total hp capacity} = \frac{\text{hp} \times \text{Service factor}}{\text{Rating per inch, Table 13a, 13b, 13c}}$$

Lubrication: The horsepower established from the sprocket and speed combinations of the drive under consideration will indicate a method of lubrication. This method or a better one must be used to obtain optimum chain life. The types of lubrication as indicated on the tables are: Type I, manual, brush, or oil cup; Type II, bath or disk; Type III, circulating pump.

ADDITIONAL

Miscellaneous Topics

Locomotive Development.—The first steam locomotive which ever ran on rails was built in 1804 by Richard Trevithick, an Englishman, and the first one to be used on a commercial basis was built by Matthew Murray, another Englishman. In 1811, Blenkinsop of Leeds, had several locomotives built by Murray in order to operate a railway extending from Middletown Colliers to Leeds, a distance of three and one-half miles. Trevithick's impracticable design had a single cylinder only, but Murray used two cylinders which were utilized in driving the same shaft on which cranks were set at right angles an important arrangement common to all modern locomotives. A cog-wheel, or gear, meshing with a continuous rack laid along the road-bed was employed. These locomotives were used daily for years and were examined by George Stephenson when he began his work on locomotive development. Several years after the construction of Murray's locomotives Hedley and Stephenson demonstrated that the gear and rack method of propulsion was unnecessary, and that the frictional resistance of smooth drivers would supply adequate tractive power. Stephenson's name will always be associated with locomotive development owing to his accomplishments in perfecting the locomotive and in establishing it on a commercial basis. His first locomotive was tried on the Killing worth Railway in 1814. The first locomotive to be used in the United States was imported from England in 1829.

Wheatstone Bridge.—The most generally used method for the measurement of the ohmic resistance of conductors is by the use of the *Wheatstone bridge*. In a simple form (See Fig. 1.) it comprises two resistance coils the ratio of the resistances of which is known, and a third, generally adjustable, resistance of known value. These are connected in circuit with the unknown resistance to be measured, a galvanometer, and a source of current, as in the diagram.

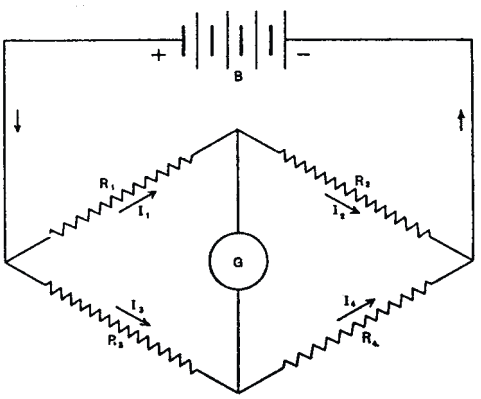

Fig. 1. Wheatstone Bridge

The adjustable resistance and the "bridge arms," if necessary, are adjusted until the galvanometer indicates no flow of current. The value of the unknown resistance is thus measured in terms of the known resistance and the known ratio of the bridge arms. In the diagram, R_1, R_2, R_3, and R_4 are resistances, B a source of electromotive force and I_1, I_2, I_3 and I_4 currents through the resistances; G is a galvanometer. If the relation of the various resistances is such that no current flows through G, then I_1 equals I_2, and I_3 equals I_4; also I_1R_1 equals I_3R_3, and I_2R_2 equals I_4R_4, there being no electromotive forces in the triangles R_1R_3G and R_2R_4G. It follows, therefore, that

$$\frac{I_1}{I_3} = \frac{R_3}{R_1}, \qquad \text{and} \qquad \frac{I_2}{I_4} = \frac{R_4}{R_2}$$

www.EngineeringEBooksPdf.com

and hence, as

$$\frac{I_1}{I_3} = \frac{I_2}{I_4}, \qquad \text{it follows that} \qquad \frac{R_3}{R_1} = \frac{R_4}{R_2}$$

If one of these resistances, R_1 for instance, is unknown, it may then be found through the equation:

$$R_1 = \frac{R_2 R_3}{R_4}$$

Wheatstone bridges are made in many forms. The three known resistances are made adjustable and are usually made of many spools of special resistance wire. The resistances are usually varied by short-circuiting a greater or smaller number of these spools.

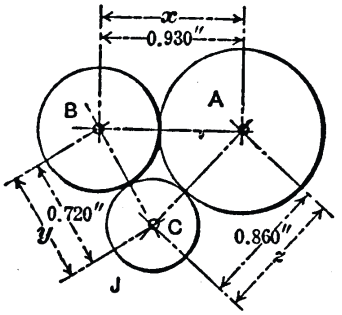
Wax Impressions .— A wax impression of a sample or model is sometimes required in the manufacture of articles made from metal. To make a wax impression, proceed as follows: Oil the surface, of which the impression is to be made, very slightly with a few drops of oil applied to a little waste. Then take common bees wax and melt it slowly, without boiling. Mix it with one or two tablespoonfuls of lamp black to half a tumbler of beeswax, and stir the mixture. In order to make the wax impression show up clearly, take a fine hair brush and brush a small amount of powdered graphite or rouge over the object of which the impression is to be made.

Winchester Bushel.— A measure of capacity or volume, legal in the United States, and equal to 2150.42 cubic inches. This measure has not been legal in Great Britain since 1825, when it was superseded by the Imperial bushel which is equal to 2218.19 cubic inches.

Miner's Inch.— The term "miner's inch," used in western United States for measuring the flow of a stream of water, is more or less indefinite, because different values have been assigned to it; thus, the amount of water corresponding to a miner's inch varies from 1.36 to 1.73 cubic feet per minute, according to the method used for the measurement. The California Legislature, by an Act of 1901, prescribed that the miner's inch should be equivalent to 1.5 cubic feet of water per minute, measured through any aperture or orifice. The most common measurement is through an aperture 2 inches high and through a plank 1¼ inches thick, the width of the aperture being whatever length is required. The lower edge of the aperture is placed 2 inches above the bottom of the measuring box and the plank is 5 inches high above the aperture, so that the head will be 6 inches above the center of the stream through the orifice. Each square inch of the opening represents a miner's inch, and the amount of water that will flow through it equals about 1½ cubic feet per minute.

Locating Holes by the Disk Method.— When machining holes in comparatively small precision work, three carefully centered disks are sometimes used to align the respective holes with the lathe spindle. These disks are made to such diameters that when their peripheries are in contact, each disk center will coincide with the position of the hole to be machined; the centers are then used for locating the work. The diameters of the disks can be found as follows: Subtract dimension y from x, thus obtaining the difference between the radii of disks C and A; add this difference to dimension z to obtain the diameter of disk A; subtract the radius of disk A from the center distance x to obtain the radius of B; subtract the radius of B from dimension y to obtain the radius of C.

www.EngineeringEBooksPdf.com



Example: 0.930 – 0.7 20 = 0.210, or the difference between the radii of disks *C* and *A*. The diameter of *A* equals 0.210 + 0.860 = 1.070 inch, and the radius equals 1.070 ÷ 2 = 0.535 inch. The radius of *B* = 0.930 – 0.535 = 0.395 inch. The radius of *C* = 0.720 – 0.395 = 0.325 inch.

Electrical Cord Gage Rating.—The following tables shows the correct minimum recommended electrical cord size to use depending on supply voltage, cord length, and nameplate ampere rating of connected load. A smaller gage number is a larger cord.

Minimum Gage for Cord Sets by Voltage, Length, and Load

Voltage	Length of Cord, Feet			
120V	0 - 25	26 - 50	51 - 100	101 - 150
240V	0 - 50	51 - 100	101 - 200	201 - 300
Nameplate Ampere Rating	American Wire Gage (AWG) Minimum Gage for Cord Sets

The Slide-rule

By means of the slide-rule, various calculations may be made mechanically with greater ease and rapidity than by ordinary arithmetical methods, and usually with sufficient accuracy for all practical requirements. Slide-rules are used principally for performing multiplication and division, but they may also be used for finding powers, roots, logarithms, and trigonometrical functions, and for various other purposes. The slide-rule in its most common form consists of three main parts. There is a main body or rule, a slide, and a runner or "cursor." Scales *A* and *D* (see Fig. 1) are on the rule, and scales *B* and *C* on the slide. Fig. 1 shows the right-hand half of the rule and the left-hand half of the slide, this sectional view being shown in order to secure a larger reproduction. The runner, which is in the form of a light metal frame that is free to slide endwise along the rule, is also shown in Fig. 1. Scales *A* and *B* are alike, as are scales *C* and *D*. All four scales are of the same length, but the graduations on scales *A* and *B* are different from those on scales *C* and *D*. The graduation 1 (seen at the extreme left in Fig. 1) is in the center of the rule, and scale *A* has two parts on opposite sides of this middle point 1 that are graduated exactly alike. The left-hand half from 1 to 1 is called the *left-hand A scale*, and the right-hand half from 1 to 1, the *right-hand A scale*. As scale *B* is exactly like scale *A*, its sections are designated as the *left-hand B scale* and the *right-hand B scale*. Each end of each scale is marked by the figure 1 which is known as the *index*. Thus, the figure 1 at the left-hand end of a scale is called the *left-hand index*, and figure 1 at the right-hand end is called the *right-hand index*.

As will be seen, the divisions on a slide-rule are not uniform. For example, that part of the left-hand *D* scale between divisions 1 and 2 (see enlarged detailed view, Fig. 2) is divided into ten main parts, no two of which are equal. Nevertheless, each of these main spaces represents 0.1. Each main space is subdivided into ten unequal parts, each of which represents one-tenth of 0.1, or 0.01. On the scales *A* and *B*, each of the ten main spaces between 1 and 2 is divided into only five parts; therefore, each subdivision represents 0.02. It is not possible to divide the spaces between graduations 4 and 5, 6 and 7, 8 and 9, etc., into as many parts as between 1 and 2, or 2 and 3, because the graduation lines would be too close together; therefore, the subdivisions near the right-hand end of any of the scales represent greater values than those near the left-hand end. This fact must be kept in mind or errors will result in the use of the slide-rule.

Reading the Slide-rule Graduations.—The method of reading the graduations is indicated in Fig. 2. A small figure 1 to the right of the left-hand index 1, represents the value 1.1, the small figure 2 marks the line that represents 1.2, and so on, to the small figure 9, which denotes 1.9. The second line to the right of the left-hand index denotes 1.02, as it is the second of the ten marks between 1 and 1.1. Several other lines at different points of the scale have the values indicated. It will be noticed that in each case the reading is accurate to at least three figures, and in some cases to four. The divisions on all four of the scales on the slide-rule are such that values can be read correctly to three figures; but beyond this it is not possible to proceed accurately, although the fourth figure may be obtained by estimating with the eye the fractional part of the subdivision. For instance, the fourth figure of the reading 1.535 is possible because the point is halfway between 1.53 and 1.54.

The values of these readings are based on the assumption that the left-hand index represents 1. The value of the left-hand index of any scale may be taken as any power of 0.1 or of 10; that is, it may be taken to represent 0.1, 0.01, 0.001, etc., or 10, 100, 1000, etc. If the left-hand index of the *D* scale represents 0.01, the readings in Fig. 2 must be multiplied by 0.01, so that they become 0.0102, 0.0111, 0.0136, 0.01535, 0.01683, and 0.0229. If the left-hand index represents 1000, the readings must be multiplied by 1000. When a value has been assigned to the index, the same ratio must be maintained throughout the remainder of the scale, a line on any scale always representing the same sequence of figures, but not always the same value. The scales *C* and *D* have a greater number of subdivisions between two consecutive numbers than have the scales *A* and *B* between the same num-

http://industrialpress.com

www.EngineeringEBooksPdf.com

bers; therefore, it is customary to use the *C* and *D* scales for multiplications and divisions, as they can be read with greater ease and accuracy.

Multiplication of Whole Numbers.—In multiplying two numbers with the slide-rule, one index of the *C* scale is set opposite one of the numbers on the *D* scale, and the product is read on the *D* scale directly in line with the other number on the *C* scale.

Example: Find the product of 4×2. Move the slide to the right, as shown in Fig. 1, until the left-hand index of the *C* scale is exactly in line with 4 on the *D* scale; then, directly opposite 2 on the *C* scale, read the product, 8, on the *D* scale. The hair-line on the glass plate of the runner should be used, as shown, to determine what reading on the *D* scale is opposite 2 on the *C* scale.

Example: Find the product of 7×2. If the left-hand index of the *C* scale is set to 7 on the *D* scale, the 2 on the *C* scale will be far to the right of the end of the *D* scale, and no result can be read. In such a case as this, move the slide to the left until the right-hand index of the *C* scale is opposite 2 on the *D* scale; then, opposite 7 on the *C* scale will be found the small Fig. 4 on the *D* scale, which is the point corresponding to 1.4; but 1.4 is not the product of 7 and 2, as $7 \times 2 = 14$. However, neglecting the decimal point, the figures of the result are correct. It becomes evident, therefore, that while the slide-rule will correctly show the first two, three, or four figures of the result, it will not always indicate the correct number of figures preceding the decimal point. The following simple rule may be used to find the number of figures in the product of two whole numbers:

Rule: If the result is obtained with the slide projecting to the left, the number of figures in the product is equal to the sum of the numbers of figures in the two numbers; but, if the slide projects to the right, the number of figures in the product is one less than the sum of the numbers of figures in the two numbers.

For instance, apply this rule to the example illustrated by Fig. 1. In this case, each number contains one figure, and the slide projects to the right; therefore, the number of figures in the result must be $(1 + 1) - 1 = 1$.

Example: Let the product of 223×7285 be required. Set the right-hand index of the *C* scale to 223 on the *D* scale, as shown in Fig. 3. It is not possible to determine the exact point on the *C* scale corresponding to 7285, as that scale, between 7 and 8, can be read accurately to only two figures, while the third must be approximated. So the runner is set with its hair-line at the position corresponding to 729 on the *C* scale, as nearly as can be judged. Below, on the *D* scale, the hair-line points to 1625, as nearly as can be read; hence, 1625 forms the first four figures of the result. As the slide projects to the left, the product must contain $3 + 4 = 7$ figures, according to the rule. Therefore the first four figures 1625 must be increased to seven by the addition of ciphers at the right, giving 1,625,000. The actual product, worked out in the usual way, is 1,624,555, which shows that the slide-rule gives the correct result to the third figure.

Multiplication of Decimals.—If the numbers to be multiplied are decimals or mixed numbers, disregard the decimal points for the time being and treat each as a whole number. Find the product of the whole numbers as already explained, and then point off as many decimal places as there are in both original numbers.

Example: Let the product of 335.75×0.00264 be required. Neglecting the decimal points, these numbers become 33,575 and 264. As the scales cannot be read accurately to more than three places, the first of the numbers may be written 33,600. Set the left-hand index of the *C* scale to 336 on the *D* scale, and opposite 264 on the *C* scale, as indicated by the hair-line, read 886 on the *D* scale. As the slide projects to the right, the number of figures in the product is $5 + 3 - 1 = 7$; that is, four ciphers must be added to the three figures read on the *D* scale, giving 8,860,000 as the product of 33,600 and 264 on the rule. But the original numbers, 335.75 and 0.00264, have two decimal places and five decimal places,

respectively, or seven decimal places in all; hence, seven places must be pointed off in the product of the whole numbers, giving 0.8860000, or simply 0.886, as the required result.

Continued Multiplication.—Continued multiplication can be performed very quickly by the use of the slide-rule. For example, suppose that the result of $6.3 \times 1.25 \times 965.5 \times 0.47$ is required. Neglecting decimal points for the time being, and writing all the numbers as whole numbers, the problem becomes $63 \times 125 \times 9655 \times 47$. Set the left-hand index of the *C* scale to 63 on the *D* scale and move the runner until the hair-line is over 125 on the *C* scale, as shown in Fig. 4. Now, without disturbing the runner, move the slide to the left until the right-hand index of the *C* scale is under the hair-line, and then, leaving the slide stationary, move the runner until the hair-line is over 9655 on the *C* scale. Finally without moving the runner set the slide with the right-hand index of the *C* scale under the hair-line. Then, without moving the slide, set the hair-line over 47 on the *C* scale. The result, read on the *D* scale under the hair-line, is 357. In obtaining this result, however, the slide projected once to the right and twice to the left; so taking the sum of the numbers of figures in all the factors, treated as whole numbers, and subtracting 1 for the time that the slide projected to the right, the number of figures in the product is found to be $(2 + 3 + 4 + 2) - 1 = 10$; that is, the product of the whole numbers is 3,570,000,000. But, the original factors contain $1 + 2 + 1 + 2 = 6$ decimal places, which must be pointed off in the final result; hence, the required product is 3570.000000, or simply 3570.

In this example there are three settings of the slide, each representing one process of multiplication. The first gives the product of 63 and 125; the second gives the product of (63×125) and 9655; and the third gives the product of $(63 \times 125 \times 9655)$ and 47. The hair-line on the runner serves to designate the product obtained at each setting.

Division of Whole Numbers.—Division is simply a reversal of multiplication. The number to be divided, or the dividend, is found on the *D* scale, and the hair-line of the runner is set over it. The divisor is found on the *C* scale and is set directly under the hair-line, also. The quotient is then read from the *D* scale at a point opposite the index of the *C* scale. In performing the division of whole numbers by the aid of the slide-rule, two cases may arise: The dividend may exceed the divisor or the divisor may exceed the dividend. If the dividend is the greater, the quotient will be a whole number or a mixed number. To find the number of figures in the whole-number part of the quotient, the following simple rule may be used:

Rule: If the slide projects to the left, the number of figures in the whole. number part of the quotient is equal to the difference between the number of figures in the dividend and the number of figures in the divisor; but, if the slide projects to the right, the number of figures in the whole-number part of the quotient is 1 plus this difference.

Example: To illustrate the application of this rule, suppose that the quotient of $1325 \div 592$ is required. Set the runner so that the hair-line is directly over 1325 on the *D* scale, as in Fig. 5. Next, without moving the runner, set the slide so that 592 on the *C* scale is directly under the hair-line. Then, opposite the right-hand index of the *C* scale will be found 224 on the *D* scale. As there are four figures in the dividend and three in the divisor, and the slide projects to the left, the number of figures in the whole-number part of the quotient, according to the rule, is $4 - 3 = 1$; therefore, the result is 2.24.

When Divisor is Greater than Dividend.—If the divisor is greater than the dividend, a different rule must be used, because the result will then be wholly a decimal. The slide and the runner are set in the same way as previously described, but the decimal point is located according to the following rule:

Rule: If the slide projects to the left, the number of ciphers between the decimal point and the first figure of the quotient is equal to the difference between the number of figures in the divisor and the number of figures in the dividend; but, if the slide projects to the right, the number of ciphers is 1 less than this difference.

Example: Let the quotient of 176 ÷ 625 be required. Setting the runner and the slide as already explained, the result is found to be 282, with the slide projecting to the left. Then, the number of ciphers between the decimal the point and the first figure must be 3 – 3 = 0, since the divisor and the dividend each three figures; that is, the first figure immediately follows the decimal point, and the result is 0.282.

Division of Decimals.— The division of decimals and mixed numbers by means of the slide-rule does not differ in principle from the division of whole numbers. The only difficulty that arises is that of locating the decimal point in the quotient. As the adding of ciphers to the right of a decimal number does not affect its value — that is, 0.2 = 0.20 = 0.200, and so on — the following rule may be formulated:

Rule: If the problem requires the division of decimals, add ciphers to either the dividend or the divisor until both have the same number of decimal places. Then ignore the decimal points in the new numbers thus obtained, converting them into whole numbers, perform the division as already explained, and locate the decimal point by the proper rule as given in connection with the division of whole numbers.

Example: As an illustration of the method to be followed, let the quotient of 0.236 ÷ 926 be required. The divisor, 926, may be written 926.000 without changing its value, and the problem then becomes 0.236 ÷ 926,000; or, dropping the decimal points, and treating both as whole numbers, the problem is 236 ÷ 926,000. The runner and slide are set is explained for whole numbers. The slide projects to the left and the quotient on the *D* scale is 255. There are six figures in the divisor and three in the dividend; hence, the number of ciphers intervening between the decimal point and the first figure is 6 – 3 = 3. The result, therefore, must be 0.000255.

Squares of Numbers.— The squares and square roots of numbers can readily be found by using the slide-rule. The *A* and *D* scales only are used in finding the square of a number. Set the runner so that the hair-line stands over the number on the *D* scale and the square of that number will be found on the *A* scale under the hair-line.

Example: Find the square of 152.7. Set the runner, as shown in Fig. 6, so that the hair-line is over 1527 on the *D* scale, and under the hair-line on the *A* scale will be found 233. The number of whole-number places and decimal places in the square can easily be found. If the result is read from the left-hand *A* scale, the square contains one less than twice as many figures as there are in the original number; whereas, if it is read from the right-hand *A* scale, the square contains twice as many figures as the original number; and if there is a decimal, there will be twice as many places as in the original number. In the above problem, the original number contains four figures and the result is found on the left-hand *A* scale; hence, the number of figures in the square is (2 × 4) – 1 = 7. There must also be 2 × 1 = 2 decimal places in the final result. Therefore, adding ciphers to 233 to make seven figures and then pointing off two decimal places, the required square is found to be 23,300.00, or 23,300.

Square Root.— The square root of a number is found by reversing the process of finding the square; that is, the number is located on the *A* scale and the root is found directly below, on the *D* scale, the hair-line being used to make the readings accurately. If the number is a whole number or a mixed number and contains an *odd* number of figures in the whole-number part, or if it is wholly a decimal and has an *odd* number of ciphers directly following the decimal point, the left-hand *A* scale must be used; in all other cases, the right-hand *A* scale is used. Let *N* represent the number of figures in the whole-number part, *N′* the number of ciphers directly following the decimal point, in the root, and *n* the same numbers in the original number.

Then, if the left-hand *A* scale is used, $N = \frac{n+1}{2}$ and $N' = \frac{n-1}{2}$

If the right-hand *A* scale is used, $N = N' = \frac{n}{2}$

www.EngineeringEBooksPdf.com

The finding of a square root is illustrated in Fig. 6.

Example: Let the square root of 2.33 be required. As there is an odd number of figures in the whole-number part, the left-hand *A* scale is used, and below, on the *D* scale, 1527 is read. With the left-hand *A* scale in use,

$$N = \frac{n+1}{2} = \frac{1+1}{2} = 1$$

Hence, the square root is 1.527.

It is very probable that the number of figures preceding the decimal point, or the number of ciphers following the decimal point, in a square root can be determined more easily and quickly by inspection than by the foregoing rules, because by pointing off the given number into periods of two figures each, as taught in arithmetic, the desired information as to the location of the decimal point in the root can be seen at a glance. It is absolutely necessary, however, to use some form of rule, such as that given, to determine whether the left-hand or the right-hand *A* scale is to be used.

Cubes of Numbers.— Finding the cube of a number requires the use of all four scales. The index of the *C* scale is set to the given number on the *D* scale and, opposite the same number on the *left-hand B* scale, the cube is read from the *A* scale. Three cases may arise, as follows:

Case I: The slide may project to the left and the cube be found on the left-hand *A* scale.

Case II: The slide may project to the right and the cube be found on the right-hand *A* scale.

Case III: The slide may project to the right and the cube be found on the left-hand *A* scale.

If the number contains a decimal, ignore the decimal point for the time being and treat it as a whole number. Let *N* represent the number of figures in the cube and *n* the number of figures in the given number. Then:

$N = 3n$, for *Case I*;

$N = 3n - 1$, for *Case II*;

$N = 3n - 2$, for *Case III*.

After the total number of figures has been found by one of these rules, point off three times as many places as there are decimal places in the given number, and the result will be the required cube of the given number:

Example: To illustrate, suppose that 36.8^3 is to be found. Treat it as a whole number, 368, and set the left-hand index of the *C* scale to 368 on the *D* scale, as in Fig. 7. Then, opposite 368 on the left-hand *B* scale will be found 5 on the *A* scale. As this setting falls under *Case II*, $N = (3 \times 3) - 1 = 8$; hence, the reading is 50,000,000. There is one decimal place in the given number, so that three places must be pointed off in the result, giving 50,000.000, or simply 50,000, as the required cube.

The cube can be found quite as readily by multiplying the number together three times; that is, $36.8^3 = 36.8 \times 36.8 \times 36.8$. This continued multiplication can be performed as previously described, and the position of the decimal point be determined by the rules given in that connection. This method will doubtless be found easier to remember than the one outlined above, involving three cases with as many different rules.

Cube Root.— The operation of finding the cube root is the reverse of finding the cube, and the method of determining the number of figures in the root, preceding or following the decimal point, is the same as that used in arithmetic; that is, the number is pointed off into periods of three figures each, beginning at the decimal point, and the root then contains one figure for each period or part of a period. If the number contains a decimal, add ciphers to the right of it, if necessary, so that the number of figures in the decimal part will be exactly divisible by 3, without a remainder. The scales and indexes to be used in finding the cube

root depend upon the number of figures in the first period at the left, not counting ciphers when they *immediately* follow the decimal point. The rules to be followed are:

Case I: If there are three figures in the first period, use the left-hand *A* scale, left-hand *B* scale, and the right-hand index of the *C* scale.

Case II: If there are two figures in the first period, use the right-hand *A* scale, left-hand *B* scale, and the left-hand index of the *C* scale.

Case III: If there is one figure in the first period, use the left-hand *A* scale, left-hand *B* scale and the left-hand index of the *C* scale.

Example: Find the cube root of 0.05. Add ciphers to make three figures, giving 0.050, thus forming one period of three figures. This indicates that the first figure of the root immediately follows the decimal point. As there are two figures, 50, in the first period, "050," the right-hand *A* scale and the left-hand index of the *C* scale are used. Set the runner so that the hair-line is across 5 on the right-hand *A* scale, as in Fig. 7. Then move the slide until the reading on the left-hand *B* scale under the hair-line is exactly equal to that on the *D* scale opposite the left-band index of the *C* scale. This reading on the *D* scale, 368, is the result required. The first figure of the root must follow the decimal point; therefore, the root is 0.368.

Use of K Scale for Cubes and Cube Roots: Some slide rules are equipped with a *K* scale for finding cubes and cube roots in one setting. To find the cube of a number, set the runner so that the hair-line stands over the number on the *D* scale; read the cube on the *K* scale.

To find the cube root of a number the reverse procedure is used, that is, the hair-line is set over the number on the proper section of the *K* scale and the cube root is read on the *D* scale. To determine which of the three sections of the *K* scale to use, point off the number into periods of three figures, starting at the decimal point; the number of digits in the extreme left-hand period will indicate the section of the *K* scale to use. For example, 4′567.89 has one digit in the extreme left-hand period; therefore, use the left section of the *K* scale. The number 45′678.9 has two digits; use the center section of the *K* scale. The number ′456.789 has three digits; use the right section of the *K* scale.

For the Cube Root of a Decimal Fraction: Count the number of zeros between the decimal point and the first significant figure; divide the number of zeros by 3; if the remainder is 2, use the left section of the *K* scale; if the remainder is 1, use the center section; and if the remainder is 0, use the right section. For example, the number 0.000000082 has 7 zeros before the 8 so that $7 \div 3 = 2$ and 1 left over, therefore, use the center section of the *K* scale.

Diameters and Circumferences of Circles.— The ratio of the circumference of a circle to the diameter is $3.1416 = \pi$, and this value is marked by an extra line on the *A* and *B* scales, on many rules. It is used in finding the circumference from the diameter by multiplication, or the diameter from the circumference by division. In either instance, the *A* and *B* scales are used. The left-hand index of the *B* scale is set to π on the *A* scale, and opposite the given diameter on the *B* scale is read the circumference on the *A* scale; or, the value π on the *B* scale is set to the given circumference on the *A* scale, and opposite the index of the *B* scale the required diameter is read from the *A* scale. This multiplication or division is performed exactly as in using the *C* and *D* scales for the same kind of operation.
