90th ANNIVERSARY EDITION

MARKS' STANDARD HANDBOOK FOR MECHANICAL ENGINEERS

11th EDITION

EUGENE A. AVALLONE
THEODORE BAUMEISTER III
ALI M. SADEGH

Marks'

Standard Handbook for Mechanical Engineers

Revised by a staff of specialists

EUGENE A. AVALLONE *Editor*

Consulting Engineer; Professor of Mechanical Engineering, Emeritus
The City College of the City University of New York

THEODORE BAUMEISTER III *Editor*

Retired Consultant, Information Systems Department
E. I. du Pont de Nemours & Co.

ALI M. SADEGH *Editor*

Consulting Engineer; Professor of Mechanical Engineering
The City College of the City University of New York

Eleventh Edition

New York Chicago San Francisco Lisbon London Madrid
Mexico City Milan New Delhi San Juan Seoul
Singapore Sydney Toronto

The McGraw·Hill Companies

Library of Congress Cataloged The First Issue
of this title as follows:

Standard handbook for mechanical engineers. 1st-ed.;
1916–

New York, McGraw-Hill.

v. Illus. 18–24 cm.

Title varies: 1916–58; Mechanical engineers' handbook.
Editors: 1916–51, L. S. Marks.—1958– T. Baumeister.
Includes bibliographies.
1. Mechanical engineering—Handbooks, manuals, etc. I. Marks,
Lionel Simeon, 1871– ed. II. Baumeister, Theodore, 1897–
ed. III. Title; Mechanical engineers' handbook.
TJ151.S82 502'.4'621 16–12915

Library of Congress Catalog Card Number: 87-641192

MARKS' STANDARD HANDBOOK FOR MECHANICAL ENGINEERS

1 2 3 4 5 6 7 8 9 0 DOW/DOW 0 1 0 9 8

ISBN-13: 978-0-07-142867-5
ISBN-10: 0-07-142867-4

The sponsoring editor for this book was Larry S. Hager, the editing supervisor was David E. Fogarty, and the production supervisor was Richard C. Ruzycka. It was set in Times Roman by International Typesetting and Composition. The art director for the cover was Anthony Landi.

Printed and bound by RR Donnelley.

This book is printed on acid-free paper.

The editors and the publisher will be grateful to readers who notify them of any inaccuracy or important omission in this book.

Contributors

Abraham Abramowitz* *Consulting Engineer; Professor of Electrical Engineering, Emeritus, The City College of The City University of New York* (ILLUMINATION)

Vincent M. Altamuro *President, VMA Inc., Toms River, NJ* (MATERIAL HOLDING, FEEDING, AND METERING. CONVEYOR MOVING AND HANDLING. AUTOMATED GUIDED VEHICLES AND ROBOTS. MATERIAL STORAGE AND WAREHOUSING. METHODS ENGINEERING. AUTOMATIC MANUFACTURING. INDUSTRIAL PLANTS)

Charles A. Amann *Principal Engineer, KAB Engineering* (AUTOMOTIVE ENGINEERING)

Farid M. Amirouche *Professor of Mechanical and Industrial Engineering, University of Illinois at Chicago* (INTRODUCTION TO THE FINITE-ELEMENT METHOD. COMPUTER-AIDED DESIGN, COMPUTER-AIDED ENGINEERING, AND VARIATIONAL DESIGN)

Yiannis Andreopoulos *Professor of Mechanical Engineering, The City College of the City University of New York* (EXPERIMENTAL FLUID MECHANICS)

William Antis* *Technical Director, Maynard Research Council, Inc., Pittsburgh, PA* (METHODS ENGINEERING)

Glenn E. Asauskas *Lubrication Engineer, Chevron Corp.* (LUBRICANTS AND LUBRICATION)

Dennis N. Assanis *Professor of Mechanical Engineering, University of Michigan* (INTERNAL COMBUSTION ENGINES)

Eugene A. Avallone *Consulting Engineer; Professor of Mechanical Engineering, Emeritus, The City College of The City University of New York* (MECHANICAL PROPERTIES OF MATERIALS. GENERAL PROPERTIES OF MATERIALS. PIPE, PIPE FITTINGS, AND VALVES. SOURCES OF ENERGY. STEAM ENGINES. MISCELLANY)

Klemens C. Baczewski *Consulting Engineer* (CARBONIZATION OF COAL AND GAS MAKING)

Glenn W. Baggley* *Former Manager, Regenerative Systems, Bloom Engineering Co., Inc.* (COMBUSTION FURNACES)

Frederick G. Baily *Consulting Engineer; Steam Turbines, General Electric Co.* (STEAM TURBINES)

Robert D. Bartholomew *Associate, Sheppard T. Powell Associates, LLC* (CORROSION)

George F. Baumeister *President, EMC Process Corp., Newport, DE* (MATHEMATICAL TABLES)

John T. Baumeister *Manager, Product Compliance Test Center, Unisys Corp.* (MEASURING UNITS)

E. R. Behnke* *Product Manager, CM Chain Division, Columbus, McKinnon Corp.* (CHAINS)

John T. Benedict* *Retired Standards Engineer and Consultant, Society of Automotive Engineers* (AUTOMOTIVE ENGINEERING)

Bernadette M. Bennett, Esq. *Associate; Carter, DeLuca, Farrell and Schmidt, LLP Melville, NY* (PATENTS, TRADEMARKS, AND COPYRIGHTS)

Louis Bialy *Director, Codes & Product Safety, Otis Elevator Company* (ELEVATORS, DUMBWAITERS, AND ESCALATORS)

Malcolm Blair *Technical and Research Director, Steel Founders Society of America* (IRON AND STEEL CASTINGS)

Omer W. Blodgett *Senior Design Consultant, Lincoln Electric Co.* (WELDING AND CUTTING)

B. Douglas Bode *Engineering Supervisor, Product Customization and Vehicle Enhancement, Construction and Forestry Div., John Deere* (OFF-HIGHWAY VEHICLES AND EARTHMOVING EQUIPMENT)

Donald E. Bolt* *Engineering Manager, Heat Transfer Products Dept., Foster Wheeler Energy Corp.* (POWER PLANT HEAT EXCHANGERS)

G. David Bounds *Senior Engineer, Duke Energy Corp.* (PIPELINE TRANSMISSION)

William J. Bow* *Director, Retired, Heat Transfer Products Department, Foster Wheeler Energy Corp.* (POWER PLANT HEAT EXCHANGERS)

*Contributions by authors whose names are marked with an asterisk were made for the previous edition and have been revised or rewritten by others for this edition. The stated professional position in these cases is that held by the author at the time of his or her contribution.

James L. Bowman* *Senior Engineering Consultant, Rotary-Reciprocating Compressor Division, Ingersoll-Rand Co.* (COMPRESSORS)

Walter H. Boyes, Jr. *Editor-in-Chief/Publisher, Control Magazine* (INSTRUMENTS)

Richard L. Brazill *Technology Specialist, ALCOA Technical Center, ALCOA* (ALUMINUM AND ITS ALLOYS)

Frederic W. Buse* *Chief Engineer, Standard Pump Division, Ingersoll-Rand Co.* (DISPLACEMENT PUMPS)

Charles P. Butterfield *Chief Engineer, National Wind Technology Center, National Renewable Energy Laboratory* (WIND POWER)

C. L. Carlson* *Late Fellow Engineer, Research Labs., Westinghouse Electric Corp.* (NONFERROUS METALS AND ALLOYS. METALS AND ALLOYS FOR NUCLEAR ENERGY APPLICATIONS)

Scott W. Case *Professor of Engineering Science & Mechanics, Virginia Polytechnic Institute and State University* (MECHANICS OF COMPOSITE MATERIALS)

Vittorio (Rino) Castelli *Senior Research Fellow, Retired, Xerox Corp.; Engineering Consultant* (FRICTION. FLUID FILM BEARINGS)

Paul V. Cavallaro *Senior Mechanical Research Engineer, Naval Undersea Warfare Center* (AIR-INFLATED FABRIC STRUCTURES)

Eric L. Christiansen *Johnson Space Center, NASA* (METEOROID/ORBITAL DEBRIS SHIELDING)

Robin O. Cleveland *Associate Professor of Aerospace and Mechanical Engineering, Boston University* (SOUND, NOISE, AND ULTRASONICS)

Gary L. Cloud *Professor, Department of Mechanical Engineering, Michigan State University* (EXPERIMENTAL STRESS AND STRAIN ANALYSIS)

Ashley C. Cockerill *Vice President and Event Coordinator, nanoTech Business, Inc.* (ENGINEERING STATISTICS AND QUALITY CONTROL)

Timothy M. Cockerill *Senior Project Manager, University of Illinois* (ELECTRONICS)

Thomas J. Cockerill *Advisory Engineer, International Business Machines Corp.* (COMPUTERS)

Aaron Cohen *Retired Center Director, Lyndon B. Johnson Space Center, NASA; Zachry Professor, Texas A&M University* (ASTRONAUTICS)

Arthur Cohen *Former Manager, Standards and Safety Engineering, Copper Development Assn.* (COPPER AND COPPER ALLOYS)

D. E. Cole *Director, Office for Study of Automotive Transportation, Transportation Research Institute, University of Michigan* (INTERNAL COMBUSTION ENGINES)

James M. Connolly *Section Head, Projects Department, Jacksonville Electric Authority* (COST OF ELECTRIC POWER)

Alexander Couzis *Professor of Chemical Engineering, The City College of the City University of New York* (INTRODUCTION TO NANOTECHNOLOGY)

Terry L. Creasy *Assistant Professor of Mechanical Engineering, Texas A&M University* (STRUCTURAL COMPOSITES)

M. R. M. Crespo da Silva* *University of Cincinnati* (ATTITUDE DYNAMICS, STABILIZATION, AND CONTROL OF SPACECRAFT)

Richard A. Dahlin *Vice President, Engineering, Walker Magnetics* (LIFTING MAGNETS)

Benjamin C. Davenny *Acoustical Consultant, Acentech Inc., Cambridge, MA* (SOUND, NOISE, AND ULTRASONICS)

William H. Day *President, Longview Energy Associates, LLC; formerly Founder and Board Chairman, The Gas Turbine Association* (GAS TURBINES)

Benjamin B. Dayton *Consulting Physicist, East Flat Rock, NC* (HIGH-VACUUM PUMPS)

Horacio M. de la Fuente *Senior Engineer, NASA Johnson Space Center* (TRANSHAB)

Donald D. Dodge *Supervisor, Retired, Product Quality and Inspection Technology, Manufacturing Development, Ford Motor Co.* (NONDESTRUCTIVE TESTING)

Andrew M. Donaldson *Project Director, Parsons E&C, Reading, PA* (COST OF ELECTRIC POWER)

Joseph S. Dorson *Senior Engineer, Columbus McKinnon Corp.* (CHAIN)

James Drago *Manager, Engineering, Garlock Sealing Technologies* (PACKING, GASKETS, AND SEALS)

Michael B. Duke *Chief, Solar Systems Exploration, Johnson Space Center, NASA* (DYNAMIC ENVIRONMENTS)

F. J. Edeskuty *Retired Associate, Las Alamos National Laboratory* (CRYOGENICS)

O. Elnan* *University of Cincinnati* (SPACE-VEHICLE TRAJECTORIES, FLIGHT MECHANICS, AND PERFORMANCE. ORBITAL MECHANICS)
Robert E. Eppich *Vice President, Technology, American Foundry Society* (IRON AND STEEL CASTINGS)
C. James Erickson* *Retired Principal Consultant, Engineering Department, E. I. du Pont de Nemours & Co.* (ELECTRICAL ENGINEERING)
George H. Ewing* *Retired President and Chief Executive Officer, Texas Eastern Gas Pipeline Co. and Transwestern Pipeline Co.* (PIPELINE TRANSMISSION)
Heimir Fanner *Chief Design Engineer, Ariel Corp.* (COMPRESSORS)
Erich A. Farber *Distinguished Service Professor Emeritus, Director Emeritus of Solar Energy and Energy Conversion Lab., University of Florida* [STIRLING (HOT AIR) ENGINES. SOLAR ENERGY. DIRECT ENERGY CONVERSION]
Raymond E. Farrell, Esq. *Partner; Carter, DeLuca, Farrell and Schmidt, LLP, Melville, NY* (PATENTS, TRADEMARKS, AND COPYRIGHTS)
D. W. Fellenz* *University of Cincinnati* (SPACE-VEHICLE TRAJECTORIES, FLIGHT MECHANICS, AND PERFORMANCE. ATMOSPHERIC ENTRY)
Chuck Fennell *Program Manager, Dalton Foundries* (FOUNDARY PRACTICE AND EQUIPMENT)
Arthur J. Fiehn* *Late Retired Vice President, Project Operations Division, Burns & Roe, Inc.* (COST OF ELECTRIC POWER)
Sanford Fleeter *McAllister Distinguished Professor, School of Mechanical Engineering, Purdue University* (JET PROPULSION AND AIRCRAFT PROPELLERS)
Luc G. Fréchette *Professor of Mechanical Engineering, Université de Sherbrooke, Canada* [AN INTRODUCTION TO MICROELECTROMECHANICAL SYSTEMS (MEMS)]
William L. Gamble *Professor Emeritus of Civil and Environmental Engineering, University of Illinois at Urbana-Champaign* (CEMENT, MORTAR, AND CONCRETE. REINFORCED CONCRETE DESIGN AND CONSTRUCTION)
Robert F. Gambon *Power Plant Design and Development Consultant* (COST OF ELECTRIC POWER)
Burt Garofab *Senior Engineer, Pittston Corp.* (MINES, HOISTS, AND SKIPS. LOCOMOTIVE HAULAGE, COAL MINES)
Siamak Ghofranian *Senior Engineer, Rockwell Aerospace* (DOCKING OF TWO FREE-FLYING SPACECRAFT)
Samuel V. Glorioso *Section Chief, Metallic Materials, Johnson Space Center, NASA* (STRESS CORROSION CRACKING)
Norman Goldberg *Consulting Engineer, Economides and Goldberg* (AIR-CONDITIONING, HEATING, AND VENTILATING)
Andrew Goldenberg *Professor of Mechanical and Industrial Engineering, University of Toronto, Canada; President and CEO of Engineering Service Inc. (ESI) Toronto* (ROBOTICS, MECHATRONICS, AND INTELLIGENT AUTOMATION)
David T. Goldman* *Late Deputy Manager, U.S. Department of Energy, Chicago Operations Office* (MEASURING UNITS)
Frank E. Goodwin *Executive Vice President, ILZRO, Inc.* (BEARING METALS. LOW-MELTING-POINT METALS AND ALLOYS. ZINC AND ZINC ALLOYS)
Don Graham *Manager, Turning Products, Carboloy, Inc.* (CEMENTED CARBIDES)
David W. Green *Supervisory Research General Engineer, Forest Products Lab., USDA* (WOOD)
Leonard M. Grillo *Principal, Grillo Engineering Co.* (MUNICIPAL WASTE COMBUSTION)
Walter W. Guy *Chief, Crew and Thermal Systems Division, Johnson Space Center, NASA* (SPACECRAFT LIFE SUPPORT AND THERMAL MANAGEMENT)
Marsbed Hablanian *Retired Manager of Engineering and R&D, Varian Vacuum Technologies* (HIGH-VACUUM PUMPS)
Christopher P. Hansen *Structures and Mechanism Engineer, NASA Johnson Space Center* (PORTABLE HYPERBARIC CHAMBER)
Harold V. Hawkins* *Late Manager, Product Standards and Services, Columbus McKinnon Corp.* (DRAGGING, PULLING, AND PUSHING. PIPELINE FLEXURE STRESSES)
Keith L. Hawthorne *Vice President—Technology, Transportation Technology Center, Inc.* (RAILWAY ENGINEERING)
V. Terrey Hawthorne *Late Senior Engineer, LTK Engineering Services* (RAILWAY ENGINEERING)
J. Edmund Hay *U.S. Department of the Interior* (EXPLOSIVES)
Terry L. Henshaw *Consulting Engineer, Magnolia, TX* (DISPLACEMENT PUMPS. CENTRIFUGAL PUMPS)
Roland Hernandez *Research Engineer, Forest Products Lab., USDA* (WOOD)
David T. Holmes *Manager of Engineering, Lift-Tech International Div. of Columbus McKinnon Corp.* (MONORAILS. OVERHEAD TRAVELING CRANES)
Hoyt C. Hottel *Late Professor Emeritus, Massachusetts Institute of Technology* (RADIANT HEAT TRANSFER)
Michael W. Hyer *Professor of Engineering Science & Mechanics, Virginia Polytechnic Institute and State University* (MECHANICS OF COMPOSITE MATERIALS)
Timothy J. Jacobs *Research Fellow, Department of Mechanical Engineering, University of Michigan* (INTERNAL COMBUSTION ENGINES)
Michael W. M. Jenkins *Professor, Aerospace Design, Georgia Institute of Technology* (AERONAUTICS)
Peter K. Johnson *Consultant* (POWDERED METALS)
Randolph T. Johnson *Naval Surface Warfare Center* (ROCKET FUELS)
Robert L. Johnston *Branch Chief, Materials, Johnson Space Center, NASA* (METALLIC MATERIALS FOR AEROSPACE APPLICATIONS. MATERIALS FOR USE IN HIGH-PRESSURE OXYGEN SYSTEMS)
Byron M. Jones* *Retired Assistant Professor of Electrical Engineering, School of Engineering, University of Tennessee at Chattanooga* (ELECTRONICS)
Scott K. Jones *Professor, Department of Accounting & MIS, Alfred Lerner College of Business & Economics, University of Delaware* (COST ACCOUNTING)
Robert Jorgensen *Engineering Consultant* (FANS)
Serope Kalpakjian *Professor Emeritus of Mechanical and Materials Engineering, Illinois Institute of Technology* (MACHINING PROCESSES AND MACHINE TOOLS)
Igor J. Karassik* *Late Senior Consulting Engineer, Ingersoll Dresser Pump Co.* (CENTRIFUGAL AND AXIAL FLOW PUMPS)
Jonathan D. Kemp *Vibration Consultant, Acentech, Inc., Cambridge, MA* (SOUND, NOISE, AND ULTRASONICS)
J. Randolph Kissell *President, The TGB Partnership* (ALUMINUM AND ITS ALLOYS)
John B. Kitto, Jr. *Babcock & Wilcox Co.* (STEAM BOILERS)
Andrew C. Klein *Professor of Nuclear Engineering, Oregon State University; Director of Training, Education and Research Partnership, Idaho National Laboratories* (NUCLEAR POWER. ENVIRONMENTAL CONTROL. OCCUPATIONAL SAFETY AND HEALTH. FIRE PROTECTION)
Doyle Knight *Professor of Mechanical and Aerospace Engineering, Rutgers University* (INTRODUCTION TO COMPUTATIONAL FLUID MECHANICS)
Ronald M. Kohner *President, Landmark Engineering Services, Ltd.* (DERRICKS)
Ezra S. Krendel *Emeritus Professor of Operations Research and Statistics, University of Pennsylvania* (HUMAN FACTORS AND ERGONOMICS. MUSCLE GENERATED POWER)
A. G. Kromis* *University of Cincinnati* (SPACE-VEHICLE TRAJECTORIES, FLIGHT MECHANICS, AND PERFORMANCE)
Srirangam Kumaresan *Biomechanics Institute, Santa Barbara, California* (HUMAN INJURY TOLERANCE AND ANTHROPOMETRIC TEST DEVICES)
L. D. Kunsman* *Late Fellow Engineer, Research Labs, Westinghouse, Electric Corp.* (NONFERROUS METALS AND ALLOYS. METALS AND ALLOYS FOR NUCLEAR ENERGY APPLICATIONS)
Colin K. Larsen *Vice President, Blue Giant U.S.A. Corp.* (SURFACE HANDLING)
Stan Lebow *Research Forest Products Technologist, Forest Products Lab., USDA* (WOOD)
John H. Lewis *Engineering Consultant; Formerly Engineering Staff, Pratt & Whitney Division, United Technologies Corp.; Adjunct Associate Professor, Hartford Graduate Center, Renssealear Polytechnic Institute* (GAS TURBINES)
Jackie Jie Li *Professor of Mechanical Engineering, The City College of the City University of New York* (FERROELECTRICS/PIEZOELECTRICS AND SHAPE MEMORY ALLOYS)
Peter E. Liley *Professor Emeritus of Mechanical Engineering, Purdue University* (THERMODYNAMICS, THERMODYNAMIC PROPERTIES OF SUBSTANCES)
James P. Locke *Flight Surgeon, NASA Johnson Space Center* (PORTABLE HYPERBARIC CHAMBER)
Ernst K. H. Marburg *Manager, Product Standards and Service, Columbus McKinnon Corp.* (LIFTING, HOISTING, AND ELEVATING. DRAGGING, PULLING, AND PUSHING. LOADING, CARRYING, AND EXCAVATING)
Larry D. Means *President, Means Engineering and Consulting* (WIRE ROPE)
Leonard Meirovitch *University Distinguished Professor Emeritus, Department of Engineering Science and Mechanics, Virginia Polytechnic Institute and State University* (VIBRATION)
George W. Michalec *Late Consulting Engineer* (GEARING)
Duane K. Miller *Manager, Engineering Services, Lincoln Electric Co.* (WELDING AND CUTTING)
Patrick C. Mock *Principal Electron Optical Scientist, Science and Engineering Associates, Inc.* (OPTICS)
Thomas L. Moser *Deputy Associate Administrator, Office of Space Flight, NASA Headquarters, NASA* (SPACE-VEHICLE STRUCTURES)
George J. Moshos* *Professor Emeritus of Computer and Information Science, New Jersey Institute of Technology* (COMPUTERS)
Eduard Muljadi *Senior Engineer, National Wind Technology Center, National Renewable Energy Laboratory* (WIND POWER)
Otto Muller-Girard* *Consulting Engineer* (INSTRUMENTS)
James W. Murdock *Late Consulting Engineer* (MECHANICS OF FLUIDS)
Gregory V. Murphy *Head and Professor, Department of Electrical Engineering, College of Engineering, Tuskegee University* (AUTOMATIC CONTROLS)
Joseph F. Murphy *Research General Engineer, Forest Products Lab., USDA* (WOOD)
John Nagy *Retired Supervisory Physical Scientist, U.S. Department of Labor, Mine Safety and Health Administration* (DUST EXPLOSIONS)
B. W. Niebel* *Professor Emeritus of Industrial Engineering, The Pennsylvania State University* (INDUSTRIAL ECONOMICS AND MANAGEMENT)
James J. Noble *Formerly Research Associate Professor of Chemical and Biological Engineering, Tufts University* (RADIANT HEAT TRANSFER)
Charles Osborn *Business Manager, Precision Cleaning Division, PTI Industries, Inc.* (PRECISION CLEANING)
D. J. Patterson *Professor of Mechanical Engineering, Emeritus, University of Michigan* (INTERNAL COMBUSTION ENGINES)
Harold W. Paxton *United States Steel Professor Emeritus, Carnegie Mellon University* (IRON AND STEEL)
Richard W. Perkins *Professor Emeritus of Mechanical, Aerospace, and Manufacturing Engineering, Syracuse University* (WOODCUTTING TOOLS AND MACHINES)
W. R. Perry* *University of Cincinnati* (ORBITAL MECHANICS. SPACE-VEHICLE TRAJECTORIES, FLIGHT MECHANICS, AND PERFORMANCE)

Kenneth A. Phair *Senior Project Engineer, Shaw Stone & Webster* (GEOTHERMAL POWER)
Orvis E. Pigg *Section Head, Structural Analysis, Johnson Space Center, NASA* (SPACE VEHICLE STRUCTURES)
Henry O. Pohl *Chief, Propulsion and Power Division, Johnson Space Center, NASA* (SPACE PROPULSION)
Nicholas R. Rafferty *Retired Technical Associate, E. I. du Pont de Nemours & Co., Inc.* (ELECTRICAL ENGINEERING)
Rama Ramakumar *PSO/Albrecht Naeter Professor and Director, Engineering Energy Laboratory, Oklahoma State University* (WIND POWER)
Pascal M. Rapier* *Scientist III, Retired, Lawrence Berkeley Laboratory* (ENVIRONMENTAL CONTROL. OCCUPATIONAL SAFETY AND HEALTH. FIRE PROTECTION)
James D. Redmond *President, Technical Marketing Services, Inc.* (STAINLESS STEELS)
Darrold E. Roen *Late Manager, Sales & Special Engineering & Government Products, John Deere* (OFF-HIGHWAY VEHICLES)
Ivan L. Ross* *International Manager, Chain Conveyor Division, ACCO* (OVERHEAD CONVEYORS)
Robert J. Ross *Supervisory Research General Engineer, Forest Products Lab., USDA* (WOOD)
J. W. Russell* *University of Cincinnati* (SPACE-VEHICLE TRAJECTORIES, FLIGHT MECHANICS, AND PERFORMANCE. LUNAR- AND INTERPLANETARY FLIGHT MECHANICS)
A. J. Rydzewski *Consultant, DuPont Engineering, E. I. du Pont de Nemours and Company* (MECHANICAL REFRIGERATION)
Ali M. Sadegh *Professor of Mechanical Engineering, The City College of The City University of New York* (MECHANICS OF MATERIALS. NONMETALLIC MATERIALS. MECHANISM. MACHINE ELEMENTS. SURFACE TEXTURE DESIGNATION, PRODUCTION, AND QUALITY CONTROL. INTRODUCTION TO BIOMECHANICS. AIR-INFLATED FABRIC STRUCTURES. RAPID PROTOTYPING.)
Anthony Sances, Jr. *Biomechanics Institute, Santa Barbara, CA* (HUMAN INJURY TOLERANCE AND ANTHROPOMETRIC TEST DEVICES)
C. Edward Sandifer *Professor, Western Connecticut State University, Danbury, CT* (MATHEMATICS)
Erwin M. Saniga *Dana Johnson Professor of Information Technology and Professor of Operations Management, University of Delaware* (OPERATIONS MANAGEMENT)
Adel F. Sarofim *Presidential Professor of Chemical Engineering, University of Utah* (RADIANT HEAT TRANSFER)
Martin D. Schlesinger *Late Consultant, Wallingford Group, Ltd.* (FUELS)
John R. Schley *Manager, Technical Marketing, RMI Titanium Co.* (TITANIUM AND ZIRCONIUM)
Matthew S. Schmidt *Senior Engineer, Rockwell Aerospace* (DOCKING OF TWO FREE-FLYING SPACECRAFT)
Wiliam C. Schneider *Retired Assistant Director Engineering/Senior Engineer, NASA Johnson Space Center; Visiting Professor, Texas A&M University* (ASTRONAUTICS)
James D. Shearouse, III *Late Senior Development Engineer, The Dow Chemical Co.* (MAGNESIUM AND MAGNESIUM ALLOYS)
David A. Shifler *Metallurgist, MERA Metallurgical Services* (CORROSION)
Rajiv Shivpuri *Professor of Industrial, Welding, and Systems Engineering, Ohio State University* (PLASTIC WORKING OF METALS)
James C. Simmons *Senior Vice President, Business Development, Core Furnace Systems Corp.* (ELECTRIC FURNACES AND OVENS)
William T. Simpson *Research Forest Products Technologist, Forest Products Lab., USDA* (WOOD)
Kenneth A. Smith *Edward R. Gilliland Professor of Chemical Engineering, Massachusetts Institute of Technology* (TRANSMISSION OF HEAT BY CONDUCTION AND CONVECTION)
Lawrence H. Sobel* *University of Cincinnati* (VIBRATION OF STRUCTURES)
James G. Speight *Western Research Institute* (FUELS)
Robert D. Steele *Project Manager, Voith Siemens Hydro Power Generation, Inc.* (HYDRAULIC TURBINES)
Stephen R. Swanson *Professor of Mechanical Engineering, University of Utah* (FIBER COMPOSITE MATERIALS)
John Symonds* *Fellow Engineer, Retired, Oceanic Division, Westinghouse Electric Corp.* (MECHANICAL PROPERTIES OF MATERIALS)
Peter L. Tea, Jr. *Professor of Physics Emeritus, The City College of the City University of New York* (MECHANICS OF SOLIDS)
Anton TenWolde *Supervisory Research Physicist, Forest Products Lab., USDA* (WOOD)
W. David Teter *Retired Professor of Civil Engineering, University of Delaware* (SURVEYING)
Michael C. Tracy *Rear Admiral, U.S. Navy* (MARINE ENGINEERING)
John H. Tundermann *Former Vice President, Research and Technology, INCO Intl., Inc.* (METALS AND ALLOYS FOR USE AT ELEVATED TEMPERATURES. NICKEL AND NICKEL ALLOYS)
Charles O. Velzy *Consultant* (MUNICIPAL WASTE COMBUSTION)
Harry C. Verakis *Supervisory Physical Scientist, U.S. Department of Labor, Mine Safety and Health Administration* (DUST EXPLOSIONS)
Arnold S. Vernick *Former Associate, Geraghty & Miller, Inc.* (WATER)
Robert J. Vondrasek* *Assistant Vice President of Engineering, National Fire Protection Assoc.* (COST OF ELECTRIC POWER)
Michael W. Washo *Senior Engineer, Retired, Eastman Kodak, Co.* (BEARINGS WITH ROLLING CONTACT)
Larry F. Wieserman *Senior Technical Supervisor, ALCOA* (ALUMINUM AND ITS ALLOYS)
Robert H. White *Supervisory Wood Scientist, Forest Products Lab., USDA* (WOOD)
John W. Wood, Jr. *Manager, Technical Services, Garlock Klozure* (PACKING, GASKETS, AND SEALS)

Symbols and Abbreviations

For symbols of chemical elements, see Sec. 6; for abbreviations applying to metric weights and measures and SI units, Sec. 1; SI unit prefixes are listed on p. 1–19.

Pairs of parentheses, brackets, etc., are frequently used in this work to indicate corresponding values. For example, the statement that "the cost per kW of a 30,000-kW plant is $86; of a 15,000-kW plant, $98; and of an 8,000-kW plant, $112," is condensed as follows: The cost per kW of a 30,000 (15,000) [8,000]-kW plant is $86 (98) [112].

In the citation of references readers should always attempt to consult the latest edition of referenced publications.

A or Å	Angstrom unit = 10^{-10} m; 3.937×10^{-11} in
A	mass number = N + Z; ampere
AA	arithmetical average
AAA	Am. Automobile Assoc.
AAMA	American Automobile Manufacturers' Assoc.
AAR	Assoc. of Am. Railroads
AAS	Am. Astronautical Soc.
ABAI	Am. Boiler & Affiliated Industries
abs	absolute
a.c.	aerodynamic center
a-c, ac	alternating current
ACI	Am. Concrete Inst.
ACM	Assoc. for Computing Machinery
ACRMA	Air Conditioning and Refrigerating Manufacturers Assoc.
ACS	Am. Chemical Soc.
ACSR	aluminum cable steel-reinforced
ACV	air cushion vehicle
A.D.	anno Domini (in the year of our Lord)
AEC	Atomic Energy Commission (U.S.)
a-f, af	audio frequency

b	barns
bar	barometer
B&S	Brown & Sharp (gage); Beams and Stringers
bbl	barrels
B.C.	before Christ
B.C.C.	body centered cubic
Bé	Baumé (degrees)
B.G.	Birmingham gage (hoop and sheet)
bgd	billions of gallons per day
BHN	Brinnell Hardness Number
bhp	brake horsepower
BLC	boundary layer control
B.M.	board measure; bench mark
bmep	brake mean effective pressure
B of M, BuMines	Bureau of Mines

BOD	biochemical oxygen demand
bp	boiling point
Bq	bequerel
bsfc	brake specific fuel consumption
BSI	British Standards Inst.
Btu	British thermal units
Btub, Btu/h	Btu per hr
bu	bushels
Bull.	Bulletin
Buweaps	Bureau of Weapons, U.S. Navy
BWG	Birmingham wire gage
c	velocity of light
°C	degrees Celsius (centigrade)
C	coulomb
CAB	Civil Aeronautics Board
CAGI	Compressed Air & Gas Inst.
cal	calories
C-B-R	chemical, biological & radiological (filters)
CBS	Columbia Broadcasting System
cc, cm^3	cubic centimetres
CCR	critical compression ratio
c to c	center to center
cd	candela
c.f.	centrifugal force
cf.	confer (compare)
cfh, ft^3/h	cubic feet per hour
cfm, ft^3/min	cubic feet per minute
C.F.R.	Cooperative Fuel Research
cfs, ft^3/s	cubic feet per second
cg	center of gravity
cgs	centimetre-gram-second
Chm. Eng.	Chemical Eng'g (New York)
chu	centrigrade heat unit
C.I.	cast iron
cir	circular
cir mil	circular mils
cm	centimetres
CME	Chartered Mech. Engr. (IMechE)
C.N.	cetane number
coef	coefficient
COESA	U.S. Committee on Extension to the Standard Atmosphere
col	column
colog	cologarithm of
const	constant
cos	cosine of
$\cos^{-1}$	angle whose cosine is, inverse cosine of
cosh	hyperbolic cosine of
$\cosh^{-1}$	inverse hyperbolic cosine of
cot	cotangent of
$\cot^{-1}$	angle whose cotangent is (see $\cos^{-1}$)
coth	hyperbolic cotangent of
$\coth^{-1}$	inverse hyperbolic cotangent of
covers	coversed sine of
c.p.	circular pitch; center of pressure
cp	candle power
cp	coef of performance
CP	chemically pure
CPH	close packed hexagonal
cpm	cycles per minute
cycles/min	
cps, cycles/s	cycles per second
CSA	Canadian Standards Assoc.
csc	cosecant of
$\csc^{-1}$	angle whose cosecant is (see $\cos^{-1}$)
csch	hyperbolic cosecant of
csch^{-1}	inverse hyperbolic cosecant of
cu	cubic
cyl	cylinder
db, dB	decibel
d-c, dc	direct current
def	definition
deg	degrees
diam. (dia)	diameter
DO	dissolved oxygen
D_2O	deuterium (heavy water)
d.p.	double pole
DP	Diametral pitch
DPH	diamond pyramid hardness
DST	daylight saving time
d^2 tons	breaking strength, d = chain wire diam. in.
DX	direct expansion
e	base of Napierian logarithmic system (= 2.7182+)
EAP	equivalent air pressure
EDR	equivalent direct radiation
EEI	Edison Electric Inst.
eff	efficiency
e.g.	exempli gratia (for example)
ehp	effective horsepower
EHV	extra high voltage
El. Wld.	Electrical World (New York)
elec	electric
elong	elongation
emf	electromotive force
Engg.	Engineering (London)
Engr.	The Engineer (London)
ENT	emergency negative thrust
EP	extreme pressure (lubricant)
ERDA	Energy Research & Development Administration (successor to AEC; see also NRC)
Eq.	equation
est	estimated
etc.	et cetera (and so forth)
et seq.	et sequens (and the following)
eV	electron volts
evap	evaporation
exp	exponential function of
exsec	exterior secant of
ext	external
°F	degrees Fahrenheit
F	farad
FAA	Federal Aviation Agency
F.C.	fixed carbon, %
FCC	Federal Communications Commission; Federal Constructive Council
F.C.C.	face-centered-cubic (alloys)

MATHEMATICAL SIGNS AND SYMBOLS

$+$	plus (sign of addition)
$+$	positive
$-$	minus (sign of subtraction)
$-$	Negative
$\pm(\mp)$	plus or minus (minus or plus)
$\times$	times, by (multiplication sign)
$\cdot$	multiplied by
$\div$	sign of division
/	divided by
:	ratio sign, divided by, is to
::	equals, as (proportion)
$<$	less than
$>$	greater than
$\ll$	much less than
$\gg$	much greater than
$=$	equals
$\equiv$	identical with
$\sim$	similar to
$\approx$	approximately equals
$\cong$	approximately equals, congruent
$\leqslant$	equal to or less than
$\geqslant$	equal to or greater than
$\neq$ $\neq$	not equal to
$\rightarrow$ $\doteq$	approaches
$\propto$	varies as
∞	infinity
$\sqrt{\ }$	square root of
$\sqrt[3]{\ }$	cube root of
$\therefore$	therefore
$\parallel$	parallel to
() [] {}	parentheses, brackets and braces; quantities enclosed by them to be taken together in multiplying, dividing, etc.
$\overline{AB}$	length of line from A to B
π	pi ($= 3.14159^{+}$)
$^\circ$	degrees
$'$	minutes
$''$	seconds
$\angle$	angle
dx	differential of x
Δ	(delta) difference
Δx	increment of x
$\partial u/\partial x$	partial derivative of u with respect to x
$\int$	integral of

$\int_b^a$	integral of, between limits a and b
$\oint$	line integral around a closed path
Σ	(sigma) summation of
$f(x)$, $F(x)$	functions of x
$\exp x = e^x$	[$e = 2.71828$ (base of natural, or Napierian, logarithms)]
∇	del or nabla, vector differential operator
∇^2	Laplacian operator
£	Laplace operational symbol
$4!$	factorial $4 = 4 \times 3 \times 2 \times 1$
$\lvert x \rvert$	absolute value of x
$\dot{x}$	first derivative of x with respect to time
$\ddot{x}$	second derivative of x with respect to time
$A \times B$	vector product; magnitude of A times magnitude of B times sine of the angle from A to B; $AB \sin \overline{AB}$
$A \cdot B$	scalar product; magnitude of A times magnitude of B times cosine of the angle from A to B; $AB \cos \overline{AB}$

The Editors

EUGENE A. AVALLONE, Editor, is Professor of Mechanical Engineering, Emeritus, The City College of the City University of New York. He has been engaged for many years as a consultant to industry and to a number of local and national governmental agencies.

THEODORE BAUMEISTER, III, Editor, is now retired from Du Pont where he was an internal consultant. His specialties are operations research, business decision making, and long-range planning. He has also taught financial modeling in the United States, South America, and the Far East.

ALI M. SADEGH, Editor, is Professor of Mechanical Engineering, The City College of the City University of New York. He is also Director of the Center for Advanced Engineering Design and Development. He is actively engaged in research in the areas of machine design, manufacturing, and biomechanics. He is a Fellow of ASME and SME.

Preface to the Eleventh Edition

The evolutionary trends underlying modern engineering practice are grounded not only on the tried and true principles and techniques of the past, but also on more recent and current advances. Thus, in the preparation of the eleventh edition of "Marks'," the Editors have considered the broad enterprise falling under the rubric of "Mechanical Engineering" and have added to and/or amended the contents to include subject areas that will be of maximum utility to the practicing engineer. That said, the Editors note that the publication of this eleventh edition has been accomplished through the combined and coordinated efforts of contributors, readers, and the Editors.

First, we recognize, with pleasure, the input from our many contributors—past, continuing, and those newly engaged. Their contributions have been prepared with care, and are authoritative, informative, and concise.

Second, our readers, who are practitioners in their own wise, have found that the global treatment of the subjects presented in the "Marks'" permits of great utility and serves as a convenient ready reference. The reading public has had access to "Marks'" since 1916, when Lionel S. Marks edited the first edition. This eleventh edition follows 90 years later. During the intervening years, "Marks'" and "Handbook for Mechanical Engineers" have become synonymous to a wide readership which includes mechanical engineers, engineers in the associated disciplines, and others. Our readership derives from a wide spectrum of interests, and it appears many find the "Marks'" useful as they pursue their professional endeavors.

The Editors consider it a given that every successive edition must balance the requests to broaden the range or depth of subject matter printed, the incorporation of new material which will be useful to the widest possible audience, and the requirement to keep the size of the Handbook reasonable and manageable. We are aware that the current engineering practitioner learns quickly that the revolutionary developments of the recent past soon become standard practice. By the same token, it is prudent to realize that as a consequence of rapid developments, some cutting-edge technologies prove to have a short shelf life and soon are regarded as obsolescent—if not obsolete.

The Editors are fortunate to have had, from time to time, input from readers and reviewers, who have proffered cogent commentary and suggestions; a number are included in this edition. Indeed, the synergy between Editors, contributors, and readers has been instrumental in the continuing usefulness of successive editions of "Marks' Standard Handbook for Mechanical Engineers."

The reader will note that a considerable portion of the tabular data and running text continue to be presented in dual units; i.e., USCS and SI. The date for a projected full transition to SI units is not yet firm, and the "Marks'" reflects that. We look to the future in that regard.

Society is in an era of information technology, as manifest by the practicing engineer's working tools. For example: the ubiquitous personal computer, its derivative use of software programs of a vast variety and number, printers, computer-aided design and drawing, universal access to the Internet, and so on. It is recognized, too, that the great leaps forward which

are thereby enhanced still require the engineer to exercise sound and rational judgment as to the reliability of the solutions provided.

Last, the Handbook is ultimately the responsibility of the Editors. The utmost care has been exercised to avoid errors, but if any inadvertently are included, the Publisher and Editors will appreciate being so informed. Corrections will be incorporated into subsequent printings.

Table 1.1.1 Segments of Circles, Given *h/c*

Given: h = height; c = chord. To find the diameter of the circle, the length of arc, or the area of the segment, form the ratio h/c, and find from the table the value of (diam/c), (arc/c); then, by a simple multiplication,

$$\text{diam} = c \times (\text{diam}/c)$$
$$\text{arc} = c \times (\text{arc}/c)$$
$$\text{area} = h \times c \times (\text{area}/h \times c)$$

The table gives also the angle subtended at the center, and the ratio of h to D.

$\frac{h}{c}$	$\frac{\text{Diam}}{c}$	Diff	$\frac{\text{Arc}}{c}$	Diff	$\frac{\text{Area}}{h \times c}$	Diff	Central angle, v	Diff	$\frac{h}{\text{Diam}}$	Diff

Table 1.1.2 Segments of Circles, Given *h/D*

Given: h = height; D = diameter of circle. To find the chord, the length of arc, or the area of the segment, form the ratio h/D, and find from the table the value of (chord/D), (arc/D), or (area/D^2); then by a simple multiplication,

$$\begin{aligned}\text{chord} &= D \times (\text{chord}/D)\\ \text{arc} &= D \times (\text{arc}/D)\\ \text{area} &= D^2 \times (\text{area}/D^2)\end{aligned}$$

This table gives also the angle subtended at the center, the ratio of the arc of the segment of the whole circumference, and the ratio of the area of the segment to the area of the whole circle.

$\frac{h}{D}$	$\frac{\text{Arc}}{D}$	Diff	$\frac{\text{Area}}{D^2}$	Diff	Central angle, v	Diff	$\frac{\text{Chord}}{D}$	Diff	$\frac{\text{Arc}}{\text{Circum}}$	Diff	$\frac{\text{Area}}{\text{Circle}}$	Diff

FORMULA: $y = e^{(r/100) \times n}$.

Table 1.1.6 Principal Which Will Amount to a Given Sum

The principal P, which, if placed at compound interest today, will amount to a given sum A at the end of n years $P = A \times x'$ or $P = A \times y'$, according as the interest (at the rate of r percent per annum) is compounded annually, or continuously; the factor x' or y' being taken from the following tables.

Values of x' (interest compounded annually: $P = A \times x'$)

Years	$r = 2$	3	4	5	6	7	8	10	12

NOTE: $x = (a - \mu)/\sigma$ where a is the observed value, μ is the mean, and σ is the standard deviation.
x is the value in the left-hand column + the value in the top row.
$F(x)$ is the probability that a point will be less than or equal to x.
$F(x)$ is the value in the body of the table. *Example:* The probability that an observation will be less than or equal to 1.04 is .8508.
NOTE: $F(-x) = 1 - F(x)$.

Table 1.1.13 Cumulative Chi-Square Distribution

$$F(t) = \int_0^t \frac{x^{(n-2)/2} e^{-x/2} dx}{2^{n/2}[(n-2)/2]!}$$

NOTE: m is the number of degrees of freedom in the numerator of F; n is the number of degrees of freedom in the denominator of F.
Values for F are in the body of the table.
G is the probability that a point, with m and n degrees of freedom will be $\leq F$.
Example: With 2 and 5 degrees of freedom, the probability that a point will be ≤ 13.3 is .99.

U.S. CUSTOMARY SYSTEM (USCS)

The USCS, often called the "inch-pound system," is the system of units most commonly used for measures of weight and length (Table 1.2.1). The units are identical for practical purposes with the corresponding English units, but the capacity measures differ from those used in the British Commonwealth, the U.S. gallon being defined as 231 cu in and the bushel as 2,150.42 cu in, whereas the corresponding British Imperial units are, respectively, 277.42 cu in and 2,219.36 cu in (1 Imp gal = 1.2 U.S. gal, approx; 1 Imp bu = 1.03 U.S. bu, approx).

Table 1.2.1 U.S. Customary Units

Units of length

12 inches	= 1 foot
3 feet	= 1 yard
5½ yards = 16½ feet	= 1 rod, pole, or perch
40 poles = 220 yards	= 1 furlong
8 furlongs = 1,760 yards = 5,280 feet	= 1 mile
3 miles	= 1 league
4 inches	= 1 hand
9 inches	= 1 span

Nautical units

6,076.11549 feet	= 1 international nautical mile
6 feet	= 1 fathom
120 fathoms	= 1 cable length
1 nautical mile per hr	= 1 knot

Surveyor's or Gunter's units

7.92 inches	= 1 link
100 links = 66 ft = 4 rods	= 1 chain
80 chains	= 1 mile
33⅓ inches	= 1 vara (Texas)

Units of area

144 square inches	= 1 square foot
9 square feet	= 1 square yard
30¼ square yards	= 1 square rod, pole, or perch
160 square rods = 10 square chains = 43,560 square feet = 5,645 sq varas (Texas)	= 1 acre
640 acres = 1 square mile =	1 "section" of U.S. government-surveyed land
1 circular inch = area of circle 1 inch in diameter	= 0.7854 sq in
1 square inch	= 1.2732 circular inches
1 circular mil	= area of circle 0.001 in in diam
1,000,000 cir mils	= 1 circular inch

Units of volume

1,728 cubic inches	= 1 cubic foot
231 cubic inches	= 1 gallon
27 cubic feet	= 1 cubic yard
1 cord of wood	= 128 cubic feet
1 perch of masonry	= 16½ to 25 cu ft

Liquid or fluid measurements

4 gills	= 1 pint
2 pints	= 1 quart
4 quarts	= 1 gallon
7.4805 gallons	= 1 cubic foot

(There is no standard liquid barrel; by trade custom, 1 bbl of petroleum oil, unrefined = 42 gal. The capacity of the common steel barrel used for refined petroleum products and other liquids is 55 gal.)

Apothecaries' liquid measurements

60 minims	= 1 liquid dram or drachm
8 drams	= 1 liquid ounce
16 ounces	= 1 pint

Water measurements

The miner's inch is a unit of water volume flow no longer used by the Bureau of Reclamation. It is used within particular water districts where its value is defined by statute. Specifically, within many of the states of the West the miner's inch is 1/50 cubic foot per second. In others it is equal to 1/40 cubic foot per second, while in the state of Colorado, 38.4 miner's inch is equal to 1 cubic-foot per second. In SI units, these correspond to $.32 \times 10^{-6}$ m^3/s, $.409 \times 10^{-6}$ m^3/s, and $.427 \times 10^{-6}$ m^3/s, respectively.

Dry measures

2 pints	= 1 quart
8 quarts	= 1 peck
4 pecks	= 1 bushel

1 std bbl for fruits and vegetables = 7,056 cu in or 105 dry qt, struck measure

Shipping measures

1 Register ton	= 100 cu ft
1 U.S. shipping ton	= 40 cu ft
	= 32.14 U.S. bu or 31.14 Imp bu
1 British shipping ton	= 42 cu ft
	= 32.70 Imp bu or 33.75 U.S. bu

Board measurements

(Based on nominal not actual dimensions; see Table 12.2.8)

1 board foot = 144 cu in = volume of board = 1 ft sq and 1 in thick

The international log rule, based upon ¼ in kerf, is expressed by the formula

$$X = 0.904762(0.22\,D^2 - 0.71\,D)$$

where X is the number of board feet in a 4-ft section of a log and D is the top diam in in. In computing the number of board feet in a log, the taper is taken at ½ in per 4 ft linear, and separate computation is made for each 4-ft section.

Weights
(The grain is the same in all systems.)

Avoirdupois weights

16 drams = 437.5 grains	= 1 ounce
16 ounces = 7,000 grains	= 1 pound
100 pounds	= 1 cental
2,000 pounds	= 1 short ton
2,240 pounds	= 1 long ton
1 std lime bbl, small	= 180 lb net
1 std lime bbl, large	= 280 lb net

Also (in Great Britain):

14 pounds	= 1 stone
2 stone = 28 pounds	= 1 quarter
4 quarters = 112 pounds	= 1 hundredweight (cwt)
20 hundredweight	= 1 long ton

Troy weights

24 grains	= 1 pennyweight (dwt)
20 pennyweights = 480 grains	= 1 ounce
12 ounces = 5,760 grains	= 1 pound

1 assay ton = 29,167 milligrams, or as many milligrams as there are troy ounces in a ton of 2,000 lb avoirdupois. Consequently, the number of milligrams of precious metal yielded by an assay ton of ore gives directly the number of troy ounces that would be obtained from a ton of 2,000 lb avoirdupois.

Apothecaries' weights

20 grains	= 1 scruple ℈
3 scruples = 60 grains	= 1 dram ʒ
8 drams	= 1 ounce ℥
12 ounces = 5,760 grains	= 1 pound

Weight for precious stones
1 carat = 200 milligrams
(Used by almost all important nations)

Circular measures

60 seconds	= 1 minute
60 minutes	= 1 degree
90 degrees	= 1 quadrant
360 degrees	= circumference
57.2957795 degrees (= 57°17′44.806″)	= 1 radian (or angle having arc of length equal to radius)

METRIC SYSTEM

In the United States the name **"metric system"** of length and mass units is commonly taken to refer to a system that was developed in France about 1800. The unit of length was equal to 1/10,000,000 of a quarter meridian (north pole to equator) and named the **metre.** A cube 1/10th metre on a side was the **litre,** the unit of volume. The mass of water filling this cube was the **kilogram,** or standard of mass; i.e., 1 litre of water = 1 kilogram of mass. Metal bars and weights were constructed conforming to these prescriptions for the metre and kilogram. One bar and one weight were selected to be the primary representations. The kilogram and the metre are now defined independently, and the litre, although for many years defined as the volume of a kilogram of water at the temperature of its maximum density, 4°C, and under a pressure of 76 cm of mercury, is now equal to 1 cubic decimeter.

In 1866, the U.S. Congress formally recognized metric units as a legal system, thereby making their use permissible in the United States. In 1893, the Office of Weights and Measures (now the National Bureau of Standards), by executive order, fixed the values of the U.S. yard and pound in terms of the meter and kilogram, respectively, as 1 yard = 3,600/3,937 m; and 1 lb = 0.453 592 4277 kg. By agreement in 1959 among the **national standards** laboratories of the **English-speaking nations,** the relations in use now are: 1 yd = 0.9144 m, whence 1 in = 25.4 mm exactly; and 1 lb = 0.453 592 37 kg, or 1 lb = 453.59 g (nearly).

THE INTERNATIONAL SYSTEM OF UNITS (SI)

In October 1960, the Eleventh General (International) Conference on Weights and Measures redefined some of the original metric units and expanded the system to include other physical and engineering units. This expanded system is called, in French, **Le Système International d'Unités** (abbreviated **SI**), and in English, **The International System of Units.**

The **Metric Conversion Act of 1975** codifies the voluntary conversion of the U.S. to the SI system. It is expected that in time all units in the United States will be in SI form. For this reason, additional tables of units, prefixes, equivalents, and conversion factors are included below (Tables 1.2.2 and 1.2.3).

SI consists of **seven base** units, **two supplementary** units, a series of **derived units** consistent with the base and supplementary units, and a series of approved prefixes for the formation of multiples and submultiples of the various units (see Tables 1.2.2 and 1.2.3). Multiple and submultiple prefixes in steps of 1,000 are recommended. (See ASTM E380-91a for further details.)

Base and **supplementary units** are **defined** [NIST Spec. Pub. 330 (2001)] as:

Metre The metre is defined as the length of path traveled by light in a vacuum during a time interval 1/299 792 458 of a second.

Kilogram The kilogram is the unit of mass; it is equal to the mass of the international prototype of the kilogram.

Second The second is the duration of 9,192,631,770 periods of the radiation corresponding to the transition between the two hyperfine levels of the ground state of the cesium 133 atom.

Ampere The ampere is that constant current which, if maintained in two straight parallel conductors of infinite length, of negligible cross section, and placed 1 metre apart in vacuum, would produce between these conductors a force equal to 2×10^{-7} newton per metre of length.

Kelvin The kelvin, unit of thermodynamic temperature, is the fraction 1/273.16 of the thermodynamic temperature of the triple point of water.

Mole The mole is the amount of substance of a system which contains as many elementary entities as there are atoms in 0.012 kilogram of carbon 12. (When the mole is used, the elementary entities must be specified and may be atoms, molecules, ions, electrons, other particles, or specified groups of such particles.)

Candela The candela is the luminous intensity, in a given direction, of a source that emits monochromatic radiation of frequency 540×10^{12} hertz and that has a radiant intensity in that direction of 1/683 watt per steradian.

Radian The unit of measure of a plane angle with its vertex at the center of a circle and subtended by an arc equal in length to the radius.

Steradian The unit of measure of a solid angle with its vertex at the center of a sphere and enclosing an area of the spherical surface equal to that of a square with sides equal in length to the radius.

SI conversion factors are listed in Table 1.2.4 alphabetically (adapted from ASTM E380-91a, "Standard Practice for Use of the International System of Units (SI) (the Modernized Metric System)." Conversion factors are written as a number greater than one and less than ten with six or fewer decimal places. This number is followed by the letter E (for exponent), a plus or minus symbol, and two digits which indicate the power of 10 by which the number must be multiplied to obtain the correct value. For example:

$$3.523\ 907\ \text{E} - 02 \text{ is } 3.523\ 907 \times 10^{-2} \text{ or } 0.035\ 239\ 07$$

An asterisk (*) after the sixth decimal place indicates that the conversion factor is exact and that all subsequent digits are zero. All other conversion factors have been rounded off.

Table 1.2.2 SI Units

Quantity	Unit	SI symbol	Formula
	Base units*		
Length	metre	m	
Mass	kilogram	kg	
Time	second	s

[a] Based on the U.S. survey foot (1 ft = 1,200/3,937 m).

[b] In 1948 a new international agreement was reached on absolute electrical units, which changed the value of the volt used in this country by about 300 parts per million. Again in 1969 a new base of reference was internationally adopted making a further change of 8.4 parts per million. These changes (and also changes in ampere, joule, watt, coulomb) require careful terminology and conversion factors for exact use of old information. Terms used in this guide are:
Volt as used prior to January 1948—volt, international U.S. (V_{INT-US})
Volt as used between January 1948 and January 1969—volt, U.S. legal 1948 (V_{INT-48})
Volt as used since January 1969—volt (V)
Identical treatment is given the ampere, coulomb, watt, and joule.

[c] This value was adopted in 1956. Some of the older International Tables use the value 1.055 04 E+03. The exact conversion factor is 1.055 055 852 62*E+03.

[d] Moment of inertia of a plane section about a specified axis.

[e] In 1964, the General Conference on Weights and Measures adopted the name "litre" as a special name for the cubic decimetre. Prior to this decision the litre differed slightly (previous value, 1.000028 dm^3), and in expression of precision, volume measurement, this fact must be kept in mind.

SYSTEMS OF UNITS

The principal units of interest to mechanical engineers can be derived from three base units which are considered to be dimensionally independent of each other. The British "gravitational system," in common use in the United States, uses units of **length, force,** and **time** as base units and is also called the "foot-pound-second system." The metric system, on the other hand, is based on the meter, kilogram, and second, units of **length, mass,** and **time,** and is often designated as the "MKS system." During the nineteenth century a metric "gravitational system," based on a kilogram-force (also called a "kilopond") came into general use. With the development of the International System of Units (SI), based as it is on the original metric system for mechanical units, and the general requirements by members of the European Community that only SI units be used, it is anticipated that the kilogram-force will fall into disuse to be replaced by the newton, the SI unit of force. Table 1.2.5 gives the base units of four systems with the corresponding derived unit given in parentheses.

In the definitions given below, the "standard kilogram body" refers to the international kilogram prototype, a platinum-iridium cylinder kept in the International Bureau of Weights and Measures in Sèvres, just outside Paris. The "standard pound body" is related to the kilogram by a precise numerical factor: 1 lb = 0.453 592 37 kg. This new "unified" pound has replaced the somewhat smaller Imperial pound of the United Kingdom and the slightly larger pound of the United States (see NBS Spec. Pub. 447). The "standard locality" means sea level, 45° latitude, or more strictly any locality in which the acceleration due to gravity has the value 9.80 665 m/s^2 = 32.1740 ft/s^2, which may be called the **standard acceleration** (Table 1.2.6).

The **pound force** is the force required to support the standard pound body against gravity, *in vacuo,* in the standard locality; or, it is the force which, if applied to the standard pound body, supposed free to move, would give that body the "standard acceleration." The word *pound* is used for the unit of both force and mass and consequently is ambiguous. To avoid uncertainty, it is desirable to call the units "pound force" and "pound mass," respectively. The slug has been defined as that mass which will accelerate at 1 ft/s^2 when acted upon by a one pound force. It is therefore equal to 32.1740 pound-mass.

The **kilogram force** is the force required to support the standard kilogram against gravity, *in vacuo,* in the standard locality; or, it is the force which, if applied to the standard kilogram body, supposed free to move, would give that body the "standard acceleration." The word *kilogram* is used for the unit of both force and mass and consequently is ambiguous. It is for this reason that the General Conference on Weights and Measures declared (in 1901) that the kilogram was the unit of mass, a concept incorporated into SI when it was formally approved in 1960.

The **dyne** is the force which, if applied to the standard gram body, would give that body an acceleration of 1 cm/s^2; i.e., 1 dyne = 1/980.665 of a gram force.

The **newton** is that force which will impart to a 1-kilogram mass an acceleration of 1 m/s^2.

Table 1.2.5 Systems of Units

Quantity	Dimensions of units in terms of L/M/F/T	British "gravitational system"	Metric "gravitational system"	CGS system	SI system
Length	L	1 ft	1 m	1 cm	1 m
Mass	M	(1 slug)		1 g	1 kg
Force	F	1 lb	1 kg	(1 dyne)	(1 N)
Time	T	1 s	1 s	1 s	1 s

Table 1.2.6 Acceleration of Gravity

Latitude, deg	g m/s²	g ft/s²	g/g^0	Latitude, deg	g m/s²	g ft/s²	g/g^0
0	9.780	32.088	0.9973	50	9.811	32.187	1.0004
10	9.782	32.093	0.9975	60	9.819	32.215	1.0013

40	9.802	32.158	0.9995	90	9.832	32.258	1.0026

NOTE: Correction for altitude above sea level: -3 mm/s² for each 1,000 m; -0.003 ft/s² for each 1,000 ft.
SOURCE: U.S. Coast and Geodetic Survey, 1912.

TEMPERATURE

The SI unit for thermodynamic temperature is the **kelvin, K,** which is the fraction 1/273.16 of the thermodynamic temperature of the triple point of water. Thus 273.16 K is the **fixed (base) point** on the **kelvin scale.**

Another unit used for the measurement of temperature is degrees **Celsius** (formerly **centigrade**), °C. The relation between a thermodynamic temperature T and a Celsius temperature t is

$$t = T - 273.15 \text{ K (the ice point of water)}$$

Thus the unit Celsius degree is equal to the unit kelvin, and a difference of temperature would be the same on either scale.

In the USCS temperature is measured in degrees **Fahrenheit, F.** The relation between the Celsius and the Fahrenheit scales is

$$t_{°C} = (t_{°F} - 32)/1.8$$

(For temperature-conversion tables, see Sec. 4.)

TERRESTRIAL GRAVITY

Standard acceleration of gravity is $g^0 = 9.80665$ m per sec per sec, or 32.1740 ft per sec per sec. This value g^0 is assumed to be the value of g at sea level and latitude 45°.

MOHS SCALE OF HARDNESS

This scale is an arbitrary one which is used to describe the hardness of several mineral substances on a scale of 1 through 10 (Table 1.2.7). The given number indicates a higher relative hardness compared with that of substances below it; and a lower relative hardness than those above it. For example, an unknown substance is scratched by quartz, but it, in turn, scratches feldspar. The unknown has a hardness of between 6 and 7 on the Mohs scale.

Table 1.2.7 Mohs Scale of Hardness

1. Talc	5. Apatite	8. Topaz
2. Gypsum	6. Feldspar	9. Sapphire
3. Calc-spar	7. Quartz	10. Diamond
4. Fluorspar		

TIME

Kinds of Time Three kinds of time are recognized by astronomers: sidereal, apparent solar, and mean solar time. The **sidereal day** is the interval between two consecutive transits of some fixed celestial object across any given meridian, or it is the interval required by the earth to make one complete revolution on its axis. The interval is constant, but it is inconvenient as a time unit because the noon of the sidereal day occurs at all hours of the day and night. The **apparent solar day** is the interval between two consecutive transits of the sun across any given meridian. On account of the variable distance between the sun and earth, the variable speed of the earth in its orbit, the effect of the moon, etc., this interval is not constant and consequently cannot be kept by any simple mechanisms, such as clocks or watches. To overcome the objection noted above, the **mean solar day** was devised. The mean solar day is the length of the average apparent solar day. Like the sidereal day it is constant, and like the apparent solar day its noon always occurs at approximately the same time of day. By international agreement, beginning Jan. 1, 1925, the astronomical day, like the civil day, is from midnight to midnight. The hours of the astronomical day run from 0 to 24, and the hours of the civil day usually run from 0 to 12 A.M. and 0 to 12 P.M. In some countries the hours of the civil day also run from 0 to 24.

The Year Three different kinds of year are used: the sidereal, the tropical, and the anomalistic. The **sidereal year** is the time taken by the earth to complete one revolution around the sun from a given star to the same star again. Its length is 365 days, 6 hours, 9 minutes, and 9 seconds. The **tropical year** is the time included between two successive passages of the vernal equinox by the sun, and since the equinox moves westward 50.2 seconds of arc a year, the tropical year is shorter by 20 minutes 23 seconds in time than the sidereal year. As the seasons depend upon the earth's position with respect to the equinox, the tropical year is the year of civil reckoning. The **anomalistic year** is the interval between two successive passages of the perihelion, viz., the time of the earth's nearest approach to the sun. The anomalistic year is used only in special calculations in astronomy.

The Second Although the second is ordinarily defined as 1/86,400 of the mean solar day, this is not sufficiently precise for many scientific purposes. Scientists have adopted more precise definitions for specific purposes: in 1956, one in terms of the length of the tropical year 1900 and, more recently, in 1967, one in terms of a specific atomic frequency.

Frequency is the reciprocal of time for 1 cycle; the unit of frequency is the **hertz** (Hz), defined as 1 cycle/s.

The Calendar The **Gregorian calendar,** now used in most of the civilized world, was adopted in Catholic countries of Europe in 1582 and in Great Britain and her colonies Jan. 1, 1752. The average length of the Gregorian calendar year is 365 ¼ − ¾₀₀ days, or 365.2425 days. This is equivalent to 365 days, 5 hours, 49 minutes, 12 seconds. The length of the tropical year is 365.2422 days, or 365 days, 5 hours, 48 minutes, 46 seconds. Thus the Gregorian calendar year is longer than the tropical year by 0.0003 day, or 26 seconds. This difference amounts to 1 day in slightly more than 3,300 years and can properly be neglected.

Standard Time Prior to 1883, each city of the United States had its own time, which was determined by the time of passage of the sun across the local meridian. A system of standard time had been used since its first adoption by the railroads in 1883 but was first legalized on Mar. 19, 1918, when Congress directed the Interstate Commerce Commission to establish limits of the standard time zones. Congress took no further steps until the **Uniform Time Act of 1966** was enacted, followed with an amendment in 1972. This legislation, referred to as "the Act," transferred the regulation and enforcement of the law to the Department of Transportation.

By the legislation of 1918, with some modifications by the Act, the contiguous United States is divided into four **time zones,** each of which, theoretically, was to span 15 degrees of longitude. The first, the **Eastern zone,** extends from the Atlantic westward to include most of Michigan and Indiana, the eastern parts of Kentucky and Tennessee, Georgia, and Florida, except the west half of the panhandle. **Eastern standard time** is

based upon the mean solar time of the 75th meridian west of Greenwich, and is 5 hours slower than **Greenwich Mean Time (GMT).** (See also discussion of UTC below.) The second or **Central zone** extends westward to include most of North Dakota, about half of South Dakota and Nebraska, most of Kansas, Oklahoma, and all but the two most westerly counties of Texas. **Central standard time** is based upon the mean solar time of the 90th meridian west of Greenwich, and is 6 hours slower than GMT. The third or **Mountain zone** extends westward to include Montana, most of Idaho, one county of Oregon, Utah, and Arizona. **Mountain standard time** is based upon the mean solar time of the 105th meridian west of Greenwich, and is 7 hours slower than GMT. The fourth or **Pacific zone** includes all of the remaining 48 contiguous states. **Pacific standard time** is based on the mean solar time of the 120th meridian west of Greenwich, and is 8 hours slower than GMT. Exact locations of boundaries may be obtained from the Department of Transportation.

In addition to the above four zones there are four others that apply to the noncontiguous states and islands. The most easterly is the **Atlantic zone,** which includes Puerto Rico and the Virgin Islands, where the time is 4 hours slower than GMT. Eastern standard time is used in the Panama Canal strip. To the west of the Pacific time zone there are the **Yukon,** the **Alaska-Hawaii,** and **Bering zones** where the times are, respectively, 9, 10, and 11 hours slower than GMT. The system of standard time has been adopted in all civilized countries and is used by ships on the high seas.

The Act directs that from the first Sunday in April to the last Sunday in October, the time in each zone is to be advanced one hour for advanced time or daylight saving time (DST). However, any state-by-state enactment may exempt the entire state from using advanced time. By this provision Arizona and Hawaii do not observe advanced time (as of 1973). By the 1972 amendment to the Act, a state split by a time-zone boundary may exempt from using advanced time all that part which is in one zone without affecting the rest of the state. By this amendment, 80 counties of Indiana in the Eastern zone are exempt from using advanced time, while 6 counties in the northwest corner and 6 counties in the southwest, which are in Central zone, do observe advanced time.

Pursuant to its assignment of carrying out the Act, the Department of Transportation has stipulated that municipalities located on the boundary between the Eastern and Central zones are in the Central zone; those on the boundary between the Central and Mountain zones are in the Mountain zone (except that Murdo, SD, is in the Central zone); those on the boundary between Mountain and Pacific time zones are in the Mountain zone. In such places, when the time is given, it should be specified as Central, Mountain, etc.

Standard Time Signals The National Institute of Standards and Technology broadcasts time signals from **station WWV,** Ft. Collins, CO, and from **station WWVH,** near Kekaha, Kaui, HI. The broadcasts by WWV are on radio carrier frequencies of 2.5, 5, 10, 15, and 20 MHz, while those by WWVH are on radio carrier frequencies of 2.5, 5, 10, and 15 MHz. Effective Jan. 1, 1975, time announcements by both WWV and WWVH are referred to as **Coordinated Universal Time, UTC,** the international coordinated time scale used around the world for most timekeeping purposes. UTC is generated by reference to International Atomic Time (TAI), which is determined by the Bureau International de l'Heure on the basis of atomic clocks operating in various establishments in accordance with the definition of the second. Since the difference between UTC and TAI is defined to be a whole number of seconds, a "leap second" is periodically added to or subtracted from UTC to take into account variations in the rotation of the earth. Time (i.e., clock time) is given in terms of 0 to 24 hours a day, starting with 0000 at midnight at Greenwich zero longitude. The beginning of each 0.8-second-long audio tone marks the end of an announced time interval. For example, at 2:15 P.M., UTC, the voice announcement would be: "At the tone fourteen hours fifteen minutes Coordinated Universal Time," given during the last 7.5 seconds of each minute. The tone markers from both stations are given simultaneously, but owing to propagation interferences may not be received simultaneously.

Beginning 1 minute after the hour, a 600-Hz signal is broadcast for about 45 s. At 2 min after the hour, the standard musical pitch of 440 Hz is broadcast for about 45 s. For the remaining 57 min of the hour, alternating tones of 600 and 500 Hz are broadcast for the first 45 s of each minute (see NIST Spec. Pub. 432). The time signal can also be received via long-distance telephone service from Ft. Collins. In addition to providing the musical pitch, these tone signals may be of use as markers for automated recorders and other such devices.

DENSITY AND RELATIVE DENSITY

Density of a body is its mass per unit volume. With SI units densities are in kilograms per cubic meter. However, giving densities in grams per cubic centimeter has been common. With the USCS, densities are given in pounds per mass cubic foot.

Table 1.2.8 Relative Densities at 60°/60°F Corresponding to Degrees API and Weights per U.S. Gallon at 60°F

$$\left(\text{Calculated from the formula, relative density} = \frac{141.5}{131.5 + \text{deg API}}\right)$$

Relative density is the ratio of the density of one substance to that of a second (or reference) substance, both at some specified temperature. Use of the earlier term *specific gravity* for this quantity is discouraged. For solids and liquids water is almost universally used as the reference substance. Physicists use a reference temperature of 4°C (= 39.2°F); U.S. engineers commonly use 60°F. With the introduction of SI units, it may be found desirable to use 59°F, since 59°F and 15°C are equivalents.

For gases, relative density is generally the ratio of the density of the gas to that of air, both at the same temperature, pressure, and dryness (as regards water vapor). Because equal numbers of moles of gases occupy equal volumes, the ratio of the molecular weight of the gas to that of air may be used as the relative density of the gas. When this is done, the molecular weight of air may be taken as 28.9644.

The relative density of liquids is usually measured by means of a **hydrometer.** In addition to a scale reading in relative density as defined above, other arbitrary scales for hydrometers are used in various trades and industries. The most common of these are the **API** and **Baumé.** The API (American Petroleum Institute) scale is approved by the American Petroleum Institute, the ASTM, the U.S. Bureau of Mines, and the National Bureau of Standards and is recommended for exclusive use in the U.S. petroleum industry, superseding the Baumé scale for liquids lighter than water. The relation between **API degrees** and relative density (see Table 1.2.8) is expressed by the following equation:

$$\text{Degrees API} = \frac{141.5}{\text{rel dens } 60^\circ/60^\circ\text{F}} - 131.5$$

The relative densities corresponding to the indications of the **Baumé hydrometer** are given in Tables 1.2.9 and 1.2.10.

Table 1.2.10 Relative Densities at 60°/60°F Corresponding to Degrees Baumé for Liquids Heavier than Water

$$\left(\text{Calculated from the formula, relative density } \frac{60^\circ}{60^\circ}\text{F} = \frac{145}{145 - \text{deg Baumé}}\right)$$

* Computed by J. A. Broadston.
† One light band equals one-half corresponding wavelength. Visible-light wavelengths range from red at 6,500 Å to violet at 4,100 Å.
‡ One helium light band = 0.000011661 in = 2937.5 Å; one krypton 86 light band = 0.0000119 in = 3,022.5 Å; one mercury 198 light band = 0.00001075 in = 2,730 Å.
§ The designations "precision measurements," etc., are not necessarily used in all metrology laboratories.

SETS, NUMBERS, AND ARITHMETIC

Sets and Elements

The concept of a set appears throughout modern mathematics. A **set** is a well-defined list or collection of objects and is generally denoted by capital letters, A, B, C, ... The objects composing the set are called **elements** and are denoted by lowercase letters, a, b, x, y, ... The notation

$$x \in A$$

is read "x is an element of A" and means that x is one of the objects composing the set A.

There are two basic ways to describe a set. The first way is to list the elements of the set.

$$A = \{2, 4, 6, 8, 10\}$$

This often is not practical for very large sets.

The second way is to describe properties which determine the elements of the set.

$$A = \{\text{even numbers from 2 to 10}\}$$

This method is sometimes awkward since a single set may sometimes be described in several different ways.

In describing sets, the symbol : is read "such that." The expression

$$B = \{x : x \text{ is an even integer}, x > 1, x < 11\}$$

is read "B equals the set of all x such that x is an even integer, x is greater than 1, and x is less than 11."

Two sets, A and B, are equal, written $A = B$, if they contain exactly the same elements. The sets A and B above are equal. If two sets, X and Y, are not equal, it is written $X \neq Y$.

Subsets A set C is a subset of a set A, written $C \subseteq A$, if each element in C is also an element in A. It is also said that C is contained in A. Any set is a subset of itself. That is, $A \subseteq A$ always. A is said to be an "improper subset of itself." Otherwise, if $C \subseteq A$ and $C \neq A$, then C is a proper subset of A.

Two theorems are important about subsets:
(Fundamental theorem of set equality)

$$\text{If } X \subseteq Y \quad \text{and} \quad Y \subseteq X, \quad \text{then } X = Y \tag{2.1.1}$$

(Transitivity)

$$\text{If } X \subseteq Y \quad \text{and} \quad Y \subseteq Z, \quad \text{then } X \subseteq Z \tag{2.1.2}$$

Universe and Empty Set In an application of set theory, it often happens that all sets being considered are subsets of some fixed set, say integers or vectors. This fixed set is called the **universe** and is sometimes denoted U.

It is possible that a set contains no elements at all. The set with no elements is called the **empty set** or the **null set** and is denoted $\varnothing$.

Set Operations New sets may be built from given sets in several ways. The **union** of two sets, denoted $A \cup B$, is the set of all elements belonging to A or to B, or to both.

$$A \cup B = \{x : x \in A \quad \text{or} \quad x \in B\}$$

The union has the properties:

$$A \subseteq A \cup B \quad \text{and} \quad B \subseteq A \cup B \tag{2.1.3}$$

The **intersection** is denoted $A \cap B$ and consists of all elements, each of which belongs to both A and B.

$$A \cap B = \{x : x \in A \quad \text{and} \quad x \in B\}$$

The intersection has the properties

$$A \cap B \subseteq A \quad \text{and} \quad A \cap B \subseteq B \tag{2.1.4}$$

If $A \cap B = \varnothing$, then A and B are called **disjoint.**

In general, a union makes a larger set and an intersection makes a smaller set.

The **complement** of a set A is the set of all elements in the universe set which are not in A. This is written

$$\tilde{}A = \{x : x \in U, \quad x \notin A\}$$

The difference of two sets, denoted $A - B$, is the set of all elements which belong to A but do not belong to B.

Algebra on Sets The operations of union, intersection, and complement obey certain laws known as **Boolean algebra.** Using these laws, it is possible to convert an expression involving sets into other equivalent expressions. The laws of Boolean algebra are given in Table 2.1.1.

Venn Diagrams To give a pictorial representation of a set, **Venn diagrams** are often used. Regions in the plane are used to correspond to sets, and areas are shaded to indicate unions, intersections, and complements. Examples of Venn diagrams are given in Fig. 2.1.1. The laws of Boolean algebra and their relation to Venn diagrams are particularly important in programming and in the logic of computer searches.

Numbers

Numbers are the basic instruments of computation. It is by operations on numbers that calculations are made. There are several different kinds of numbers.

Natural numbers, or counting numbers, denoted **N,** are the whole numbers greater than zero. Sometimes zero is included as a natural number. Any two natural numbers may be added or multiplied to give another natural number, but subtracting them may produce a negative

Table 2.1.1 Laws of Boolean Algebra

1. Idempotency	
$A \cup A = A$	$A \cap A = A$
2. Associativity	
$(A \cup B) \cup C = A \cup (B \cup C)$	$(A \cap B) \cap C = A \cap (B \cap C)$
3. Commutativity	
$A \cup B = B \cup A$	$A \cap B = B \cap A$
4. Distributivity	
$A \cup (B \cap C) = (A \cup B) \cap (A \cup C)$	$A \cap (B \cup C) = (A \cap B) \cup (A \cap C)$
5. Identity	
$A \cup \varnothing = A$	$A \cap U = A$
$A \cup U = U$	$A \cap \varnothing = \varnothing$
6. Complement	
$A \cup \tilde{}A = U$	$A \cap \tilde{}A = \varnothing$
$\tilde{}(\tilde{}A) = A$	
$\tilde{}U = \varnothing$	
$\tilde{}\varnothing = U$	
7. DeMorgan's laws	
$\tilde{}(A \cup B) = \tilde{}A \cap \tilde{}B$	$\tilde{}(A \cap B) = \tilde{}A \cup \tilde{}B$

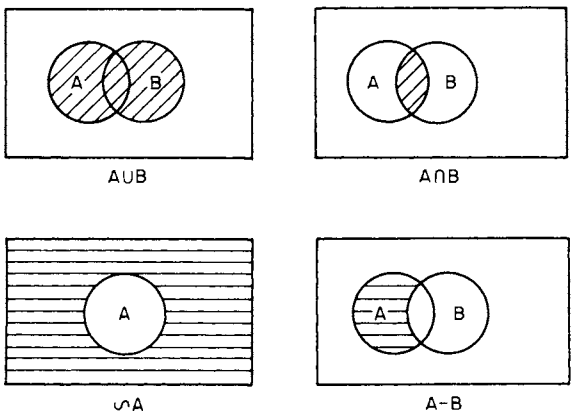

Fig. 2.1.1 Venn diagrams.

number, which is not a natural number, and dividing them may produce a fraction, which is not a natural number. When computers are used, it is important to know what kind of number is being used so the correct data type will be used as well.

Integers, or whole numbers, are denoted by **Z.** They include both positive and negative numbers and zero. Integers may be added, subtracted, and multiplied, but division might not produce an integer.

Real numbers, denoted **R,** are essentially all values which it is possible for a measurement to take, or all possible lengths for line segments. **Rational numbers** are real numbers that are the quotient of two integers, for example, $11/78$. **Irrational numbers** are not the quotient of two integers, for example, π and $\sqrt{2}$. Within the real numbers, it is always possible to add, subtract, multiply, and divide (except division by zero).

Complex numbers, or **imaginary numbers,** denoted **C,** are an extension of the real numbers that include the square root of -1, denoted i. Within the real numbers, only positive numbers have square roots. Within the complex numbers, all numbers have square roots.

Any complex number z can be written uniquely as $z = x + iy$, where x and y are real. Then x is the real part of z, denoted $\mathrm{Re}(z)$, and y is the imaginary part, denoted $\mathrm{Im}(z)$.

The **complex conjugate,** or simply conjugate of a complex number, z is $\bar{z} = x - iy$.

If $z = x + iy$ and $w = u + iv$, then z and w may be manipulated as follows:

$$z + w = (x + u) + i(y + v)$$
$$z - w = (x - u) + i(y - v)$$
$$zw = xu - yv + i(xv + yu)$$
$$\frac{z}{w} = \frac{xu + yv + i(yu - xv)}{u^2 + v^2}$$

As sets, the following relation exists among these different kinds of numbers:

$$\mathbf{N} \subseteq \mathbf{Z} \subseteq \mathbf{R} \subseteq \mathbf{C}$$

Functions

A function f is a rule that relates two sets A and B. Given an element x of the set A, the function assigns a unique element y from the set B. This is written

$$y = f(x)$$

The set A is called the **domain** of the function, and the set B is called the **range.** It is possible for A and B to be the same set.

Functions are usually described by giving the rule. For example,

$$f(x) = 3x + 4$$

is a rule for a function with range and domain both equal to **R.** Given a value, say, 2, from the domain, $f(2) = 3(2) + 4 = 10$.

If two functions f and g have the same range and domain and if the ranges are numbers, then f and g may be added, subtracted, multiplied, or divided according to the rules of the range. If $f(x) = 3x + 4$ and $g(x) = \sin(x)$ and both have range and domain equal to **R,** then

$$f + g(x) = 3x + 4 + \sin(x)$$

and

$$\frac{f}{g}(x) = \frac{3x + 4}{\sin x}$$

Dividing functions occasionally leads to complications when one of the functions assumes a value of zero. In the example f/g above, this occurs when $x = 0$. The quotient cannot be evaluated for $x = 0$ although the quotient function is still meaningful. In this case, the function f/g is said to have a **pole** at $x = 0$.

Polynomial functions are functions of the form

$$f(x) = \sum_{i=0}^{n} a_i x^i$$

where $a_n \neq 0$. The domain and range of polynomial functions are always either **R** or **C.** The number n is the degree of the polynomial.

Polynomials of degree 0 or 1 are called **linear;** of degree 2 they are called **parabolic** or **quadratic;** and of degree 3 they are called **cubic.**

The values of f for which $f(x) = 0$ are called the **roots of** f. A polynomial of degree n has at most n roots. There is exactly one exception to this rule: If $f(x) = 0$ is the constant zero function, the degree of f is zero, but f has infinitely many roots.

Roots of polynomials of degree 1 are found as follows: Suppose the polynomial is $f(x) = ax + b$. Set $f(x) = 0$ and solve for x. Then $x = -b/a$.

Roots of polynomials of degree 2 are often found using the quadratic formula. If $f(x) = ax^2 + bx + c$, then the two roots of f are given by the **quadratic formula:**

$$x_1 = \frac{-b + \sqrt{b^2 - 4ac}}{2a} \quad \text{and} \quad x_2 = \frac{-b - \sqrt{b^2 - 4ac}}{2a}$$

Roots of a polynomial of degree 3 fall into two types.

Equations of the Third Degree with Term in x^2 Absent

Solution: After dividing through by the coefficient of x^3, any equation of this type can be written $x^3 = Ax + B$. Let $p = A/3$ and $q = B/2$. The general solution is as follows:

CASE 1. $q^2 - p^3$ positive. One root is real, viz.,

$$x_1 = \sqrt[3]{q + \sqrt{q^2 - p^3}} + \sqrt[3]{q - \sqrt{q^2 - p^3}}$$

The other two roots are imaginary.

CASE 2. $q^2 - p^3 =$ zero. Three roots real, but two of them equal.

$$x_1 = 2\sqrt[3]{q} \qquad x_2 = -\sqrt[3]{q} \qquad x_3 = -\sqrt[3]{q}$$

CASE 3. $q^2 - p^3$ negative. All three roots are real and distinct. Determine an angle u between 0 and 180°, such that $\cos u = q/(p\sqrt{p})$. Then

$$x_1 = 2\sqrt{p}\cos(u/3)$$
$$x_2 = 2\sqrt{p}\cos(u/3 + 120°)$$
$$x_3 = 2\sqrt{p}\cos(u/3 + 240°)$$

Graphical Solution: Plot the curve $y_1 = x^3$, and the straight line $y_2 = Ax + B$. The abscissas of the points of intersection will be the roots of the equation.

Equations of the Third Degree (General Case)

Solution: The general cubic equation, after dividing through by the coefficient of the highest power, may be written $x^3 + ax^2 + bx + c = 0$. To get rid of the term in x^2, let $x = x_1 - a/3$. The equation then becomes $x_1^3 = Ax_1 + B$, where $A = 3(a/3)^2 - b$, and $B = -2(a/3)^3 + b(a/3) - c$. Solve this equation for x_1, by the method above, and then find x itself from $x = x_1 - (a/3)$.

Graphical Solution: Without getting rid of the term in x^2, write the equation in the form $x^3 = -a[x + (b/2a)]^2 + [a(b/2a)^2 - c]$, and solve by the graphical method.

Computer Solutions: Equations of degree 3 or higher are frequently solved by using computer algebra systems such as Mathematica or Maple.

Arithmetic

When numbers, functions, or vectors are manipulated, they always obey certain properties, regardless of the types of the objects involved. Elements may be added or subtracted only if they are in the same universe set. Elements in different universes may sometimes be multiplied or divided, but the result may be in a different universe. Regardless of the universe sets involved, the following properties hold true:

1. Associative laws. $a + (b + c) = (a + b) + c$, $a(bc) = (ab)c$
2. Identity laws. $0 + a = a$, $1a = a$
3. Inverse laws. $a - a = 0$, $a/a = 1$
4. Distributive law. $a(b + c) = ab + ac$
5. Commutative laws. $a + b = b + a$, $ab = ba$

Certain universes, for example, matrices, do not obey the commutative law for multiplication.

SIGNIFICANT FIGURES AND PRECISION

Number of Significant Figures In engineering computations, the data are ordinarily the result of measurement and are correct only to a limited number of significant figures. Each of the numbers 3.840 and 0.003840 is said to be given "correct to four figures"; the true value lies in the first case between 0.0038395 and 0.0038405. The **absolute error** is less than 0.001 in the first case, and less than 0.000001 in the second; but the **relative error** is the same in both cases, namely, an error of less than "one part in 3,840."

If a number is written as 384,000, the reader is left in doubt whether the number of correct significant figures is 3, 4, 5, or 6. This doubt can be removed by writing the number as 3.84×10^5, or 3.840×10^5, or 3.8400×10^5, or 3.84000×10^5.

In any numerical computation, the possible or desirable degree of accuracy should be decided on and the computation should then be so arranged that the required number of significant figures, and no more, is secured. Carrying out the work to a larger number of places than is justified by the data is to be avoided, (1) because the form of the results leads to an erroneous impression of their accuracy and (2) because time and labor are wasted in superfluous computation.

The unit value of the least significant figure in a number is its **precision.** The number 123.456 has six significant figures and has precision 0.001.

Two ways to represent a real number are as **fixed-point** or as **floating-point,** also known as "scientific notation."

In scientific notation, a number is represented as a product of a **mantissa** and a power of 10. The mantissa has its first significant figure either immediately before or immediately after the decimal point, depending on which convention is being used. The power of 10 used is called the **exponent.** The number 123.456 may be represented as either

$$0.123456 \times 10^3 \qquad \text{or} \qquad 1.23456 \times 10^2$$

Fixed-point representations tend to be more convenient when the quantities involved will be added or subtracted or when all measurements are taken to the same precision. Floating-point representations are more convenient for very large or very small numbers or when the quantities involved will be multiplied or divided.

Many different numbers may share the same representation. For example, 0.05 may be used to represent, with precision 0.01, any value between 0.045000 and 0.054999. The largest value a number represents, in this case 0.0549999, is sometimes denoted x^*, and the smallest is denoted x_*.

An awareness of precision and significant figures is necessary so that answers correctly represent their accuracy.

Multiplication and Division A product or quotient should be written with the smallest number of significant figures of any of the factors involved. The product often has a different precision than the factors, but the significant figures must not increase.

EXAMPLES. $(6.)(8.) = 48$ should be written as 50 since the factors have one significant figure. There is a loss of precision from 1 to 10.

$0.6 \times 0.8 = .048$ should be written as 0.5 since the factors have one significant figure. There is a gain of precision from 0.1 to 0.01.

Addition and Subtraction A sum or difference should be represented with the same precision as the least precise term involved. The number of significant figures may change.

EXAMPLES. $3.14 + 0.001 = 3.141$ should be represented as 3.14 since the least precise term has precision 0.01.

$3.14 + 0.1 = 3.24$ should be represented as 3.2 since the least precise term has precision 0.1.

Loss of Significant Figures Addition and subtraction may result in serious loss of significant figures and resultant large relative errors if the sums are near zero. For example,

$$3.15 - 3.14 = 0.01$$

shows a loss from three significant figures to just one. Where it is possible, calculations and measurements should be planned so that loss of significant figures can be avoided.

Mixed Calculations When an expression involves both products and sums, significant figures and precision should be noted for each term or factor as it is calculated, so that correct significant figures and precision for the result are known. The calculation should be performed to as much precision as is available and should be rounded to the correct precision when the calculation is finished. This process is frequently done incorrectly, particularly when calculators or computers provide many decimal places in their result but provide no clue as to how many of those figures are significant.

Significant Figures in Evaluating Functions If $y = f(x)$, then the correct number of significant figures in y depends on the number of significant figures in x and on the behavior of the function f in the neighborhood of x. In general, y should be represented so that all of $f(x)$, $f(x^*)$, and $f(x_*)$ are between y^* and y_*.

EXAMPLES.

$$\begin{aligned}
\text{sqr } (2.0) \quad \text{sqr } (1.95) &= 1.39642 \\
\text{sqr } (2.00) &= 1.41421 \\
\text{sqr } (2.05) &= 1.43178 \\
\text{so } y &= 1.4
\end{aligned}$$

$$\begin{aligned}
\sin (1°) \quad \sin (0.5) &= 0.00872 \\
\sin (1.0) &= 0.01745 \\
\sin (1.5) &= 0.02617 \\
\text{so } \sin (1°) &= 0.0
\end{aligned}$$

$$\begin{aligned}
\sin (90°) \quad \sin (89.5) &= 0.99996 \\
\sin (90.0) &= 1.00000 \\
\sin (90.5) &= 0.99996 \\
\text{so } \sin (90°) &= 1.0000
\end{aligned}$$

Note that in finding sin (90°), there was a gain in significant figures from two to five and also a gain in precision. This tends to happen when $f'(x)$ is close to zero. On the other hand, precision and significant figures are often lost when $f'(x)$ or $f''(x)$ are large.

Rearrangement of Formulas Often a formula may be rewritten in order to avoid a loss of significant figures.

In using the quadratic formula to find the roots of a polynomial, significant figures may be lost if the $ax^2 + bx + c$ has a root near zero. The quadratic formula may be rearranged as follows:

1. Use the quadratic formula to find the root that is not close to 0. Call this root x_1.
2. Then $x_2 = c/ax_1$.

If $f(x) = \sqrt{x + 1} - \sqrt{x}$, then loss of significant figures occurs if x is large. This can be eliminated by "rationalizing the numerator" as follows:

$$\frac{(\sqrt{x + 1} - \sqrt{x})(\sqrt{x + 1} + \sqrt{x})}{\sqrt{x + 1} + \sqrt{x}} = \frac{1}{\sqrt{x + 1} + \sqrt{x}}$$

and this has no loss of significant figures.

There is an almost unlimited number of "tricks" for rearranging formulas to avoid loss of significant figures, but many of these are very similar to the tricks used in calculus to evaluate limits.

GEOMETRY, AREAS, AND VOLUMES

Geometrical Theorems

Right Triangles $a^2 + b^2 = c^2$. (See Fig. 2.1.2.) $\angle A + \angle B = 90°$. $p^2 = mn$. $a^2 = mc$. $b^2 = nc$.

Oblique Triangles Sum of angles = 180°. An exterior angle = sum of the two opposite interior angles (Fig. 2.1.2).

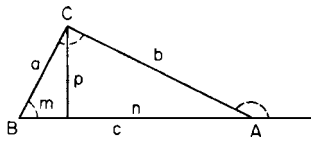

Fig. 2.1.2 Right triangle.

The medians, joining each vertex with the middle point of the opposite side, meet in the center of gravity *G* (Fig. 2.1.3), which trisects each median.

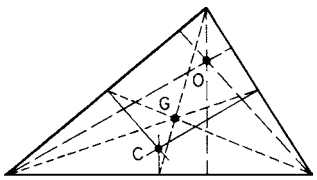

Fig. 2.1.3 Triangle showing medians and center of gravity.

The altitudes meet in a point called the **orthocenter,** *O*.

The perpendiculars erected at the midpoints of the sides meet in a point *C*, the center of the circumscribed circle. (In any triangle *G*, *O*, and *C* lie in line, and *G* is two-thirds of the way from *O* to *C*.)

The bisectors of the angles meet in the center of the inscribed circle (Fig. 2.1.4).

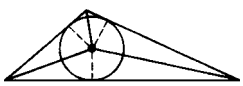

Fig. 2.1.4 Triangle showing bisectors of angles.

The largest side of a triangle is opposite the largest angle; it is less than the sum of the other two sides.

Similar Figures Any two similar figures, in a plane or in space, can be placed in "perspective," i.e., so that straight lines joining corresponding points of the two figures will pass through a common point (Fig. 2.1.5). That is, of two similar figures, one is merely an enlargement of the other. Assume that each length in one figure is k times the corresponding length in the other; then each area in the first figure is k^2 times the corresponding area in the second, and each volume in the first figure is k^3 times the corresponding volume in the second. If two lines are cut by a set of parallel lines (or parallel planes), the corresponding segments are proportional.

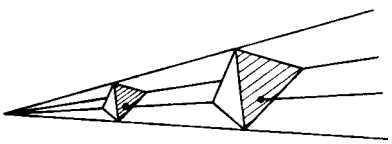

Fig. 2.1.5 Similar figures.

The Circle An angle that is inscribed in a semicircle is a right angle (Fig. 2.1.6).

A tangent is perpendicular to the radius drawn to the point of contact.

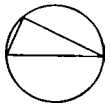

Fig. 2.1.6 Angle inscribed in a semicircle.

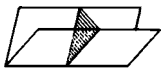

Fig. 2.1.7 Dihedral angle.

Dihedral Angles The dihedral angle between two planes is measured by a plane angle formed by two lines, one in each plane, perpendicular to the edge (Fig. 2.1.7). (For solid angles, see Surfaces and Volumes of Solids.)

In a **tetrahedron,** or triangular pyramid, the four medians, joining each vertex with the center of gravity of the opposite face, meet in a point, the center of gravity of the tetrahedron; this point is ¾ of the way from any vertex to the center of gravity of the opposite face.

The Sphere (See also Surfaces and Volumes of Solids.) If *AB* is a diameter, any plane perpendicular to *AB* cuts the sphere in a circle, of which *A* and *B* are called the poles. A great circle on the sphere is formed by a plane passing through the center.

Geometrical Constructions

To Bisect a Line *AB* (Fig. 2.1.8) (1) From *A* and *B* as centers, and with equal radii, describe arcs intersecting at *P* and *Q*, and draw *PQ*, which will bisect *AB* in *M*. (2) Lay off $AC = BD =$ approximately half of *AB*, and then bisect *CD*.

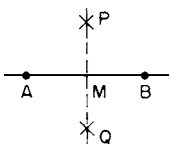

Fig. 2.1.8 Bisectors of a line.

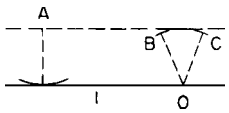

Fig. 2.1.9 Construction of a line parallel to a given line.

To Draw a Parallel to a Given Line *l* **through a Given Point** *A* (Fig. 2.1.9) With point *A* as center draw an arc just touching the line *l*; with any point *O* of the line as center, draw an arc *BC* with the same radius. Then a line through *A* touching this arc will be the required parallel. Or, use a straightedge and triangle. Or, use a sheet of celluloid with a set of lines parallel to one edge and about ¼ in apart ruled upon it.

To Draw a Perpendicular to a Given Line from a Given Point *A* **Outside the Line** (Fig. 2.1.10) (1) With *A* as center, describe an arc cutting the line at *R* and *S*, and bisect *RS* at *M*. Then *M* is the foot of the perpendicular. (2) If *A* is nearly opposite one end of the line, take any point *B* of the line and bisect *AB* in *O*; then with *O* as center, and *OA* or *OB* as radius, draw an arc cutting the line in *M*. Or, (3) use a straightedge and triangle.

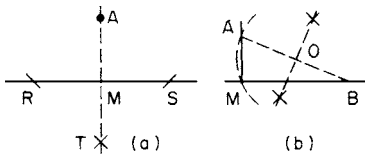

Fig. 2.1.10 Construction of a line perpendicular to a given line from a point not on the line.

To Erect a Perpendicular to a Given Line at a Given Point *P* (1) Lay off $PR = PS$ (Fig. 2.1.11), and with *R* and *S* as centers draw arcs

intersecting at A. Then PA is the required perpendicular. (2) If P is near the end of the line, take any convenient point O (Fig. 2.1.12) above the line as center, and with radius OP draw an arc cutting the line at Q. Produce QO to meet the arc at A; then PA is the required perpendicular. (3) Lay off $PB = 4$ units of any scale (Fig. 2.1.13); from P and B as centers lay off $PA = 3$ and $BA = 5$; then APB is a right angle.

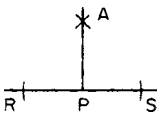

Fig. 2.1.11 Construction of a line perpendicular to a given line from a point on the line.

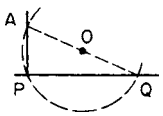

Fig. 2.1.12 Construction of a line perpendicular to a given line from a point on the line.

To Divide a Line AB into n Equal Parts (Fig. 2.1.14) Through A draw a line AX at any angle, and lay off n equal steps along this line. Connect the last of these divisions with B, and draw parallels through the other divisions. These parallels will divide the given line into n equal parts. A similar method may be used to divide a line into parts which shall be proportional to any given numbers.

To Bisect an Angle AOB (Fig. 2.1.15) Lay off $OA = OB$. From A and B as centers, with any convenient radius, draw arcs meeting at M; then OM is the required bisector.

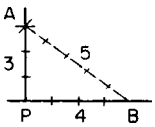

Fig. 2.1.13 Construction of a line perpendicular to a given line from a point on the line.

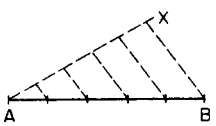

Fig. 2.1.14 Division of a line into equal parts.

To draw the bisector of an angle when the vertex of the angle is not accessible. Parallel to the given lines a, b, and equidistant from them, draw two lines a', b' which intersect; then bisect the angle between a' and b'.

To Inscribe a Hexagon in a Circle (Fig. 2.1.16) Step around the circumference with a chord equal to the radius. Or, use a 60° triangle.

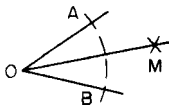

Fig. 2.1.15 Bisection of an angle.

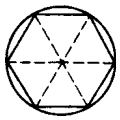

Fig. 2.1.16 Hexagon inscribed in a circle.

To Circumscribe a Hexagon about a Circle (Fig. 2.1.17) Draw a chord AB equal to the radius. Bisect the arc AB at T. Draw the tangent at T (parallel to AB), meeting OA and OB at P and Q. Then draw a circle with radius OP or OQ and inscribe in it a hexagon, one side being PQ.

To Construct a Polygon of n Sides, One Side AB Being Given (Fig. 2.1.18) With A as center and AB as radius, draw a semicircle, and divide it into n parts, of which $n - 2$ parts (counting from B) are to be used. Draw rays from A through these points of division, and complete the construction as in the figure (in which $n = 7$). Note that the center of the polygon must lie in the perpendicular bisector of each side.

To Draw a Tangent to a Circle from an external point A (Fig. 2.1.19) Bisect AC in M; with M as center and radius MC, draw arc cutting circle in P; then P is the required point of tangency.

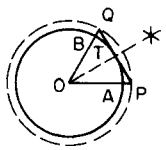

Fig. 2.1.17 Hexagon circumscribed about a circle.

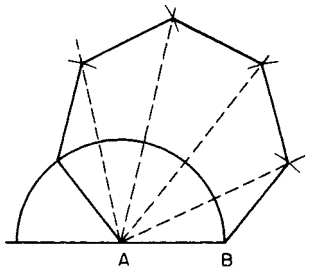

Fig. 2.1.18 Construction of a polygon with a given side.

To Draw a Common Tangent to Two Given Circles (Fig. 2.1.20) Let C and c be centers and R and r the radii ($R > r$). From C as center, draw two concentric circles with radii $R + r$ and $R - r$; draw tangents to these circles from c; then draw parallels to these lines at distance r. These parallels will be the required common tangents.

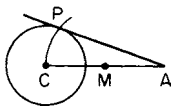

Fig. 2.1.19 Construction of a tangent to a circle.

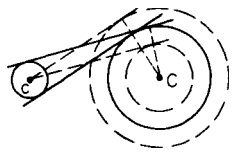

Fig. 2.1.20 Construction of a tangent common to two circles.

To Draw a Circle through Three Given Points A, B, C, or to find the center of a given circular arc (Fig. 2.1.21) Draw the perpendicular bisectors of AB and BC; these will meet at the center, O.

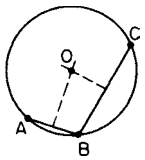

Fig. 2.1.21 Construction of a circle passing through three given points.

To Draw a Circle through Two Given Points A, B, **and Touching a Given Circle** (Fig. 2.1.22) Draw any circle through A and B, cutting the given circle at C and D. Let AB and CD meet at E, and let ET be tangent from E to the circle just drawn. With E as center, and radius ET, draw an arc cutting the given circle at P and Q. Either P or Q is the required point of contact. (Two solutions.)

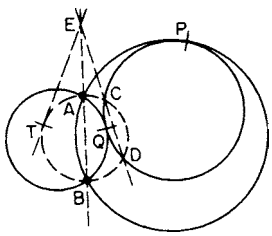

Fig. 2.1.22 Construction of a circle through two given points and touching a given circle.

To Draw a Circle through One Given Point, A, **and Touching Two Given Circles** (Fig. 2.1.23) Let S be a center of similitude for the two given circles, i.e., the point of intersection of two external (or internal)

common tangents. Through S draw any line cutting one circle at two points, the nearer of which shall be called P, and the other at two points, the more remote of which shall be called Q. Through A, P, Q draw a circle cutting SA at B. Then draw a circle through A and B and touching one of the given circles (see preceding construction). This circle will touch the other given circle also. (Four solutions.)

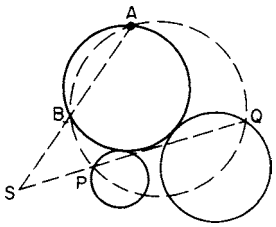

Fig. 2.1.23 Construction of a circle through a given point and touching two given circles.

To Draw an Annulus Which Shall Contain a Given Number of Equal Contiguous Circles (Fig. 2.1.24) (An annulus is a ring-shaped area enclosed between two concentric circles.) Let $R + r$ and $R - r$ be the inner and outer radii of the annulus, r being the radius of each of the n circles. Then the required relation between these quantities is given by $r = R \sin(180°/n)$, or $r = (R + r)\,[\sin(180°/n)]/[1 + \sin(180°/n)]$.

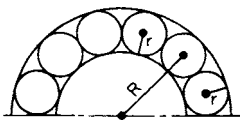

Fig. 2.1.24 Construction of an annulus containing a given number of contiguous circles.

Lengths and Areas of Plane Figures

Right Triangle (Fig. 2.1.25) $a^2 + b^2 = c^2$. Area $= \frac{1}{2}ab = \frac{1}{2}a^2 \cot A = \frac{1}{2}b^2 \tan A = \frac{1}{4}c^2 \sin 2A$.

Equilateral Triangle (Fig. 2.1.26) Area $= \frac{1}{4}a^2\sqrt{3} = 0.43301a^2$.

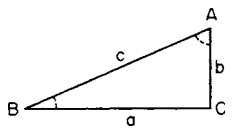

Fig. 2.1.25 Right triangle.

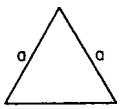

Fig. 2.1.26 Equilateral triangle.

Any Triangle (Fig. 2.1.27)

$s = \frac{1}{2}(a + b + c), t = \frac{1}{2}(m1 + m2 + m3)$

$r = \sqrt{(s-a)(s-b)(s-c)/s}$ = radius inscribed circle

$R = \frac{1}{2}\,a/\sin A = \frac{1}{2}\,b/\sin B = \frac{1}{2}\,c/\sin C$ = radius circumscribed circle

Area $= \frac{1}{2}$ base $\times$ altitude $= \frac{1}{2}ah = \frac{1}{2}ab \sin C = rs = abc/4R =$
$\pm\frac{1}{2}\{(x_1 y_2 - x_2 y_1) + (x_2 y_3 - x_3 y_2) + (x_3 y_1 - x_1 y_3)\}$,
where (x_1, y_1), (x_2, y_2), (x_3, y_3) are coordinates of vertices.

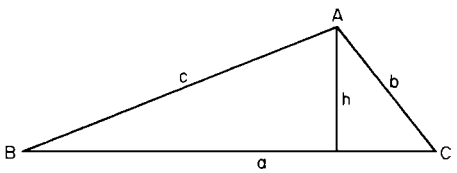

Fig. 2.1.27 Triangle.

Rectangle (Fig. 2.1.28) Area $= ab = \frac{1}{2}D^2 \sin u$, where u = angle between diagonals D, D.

Rhombus (Fig. 2.1.29) Area $= a^2 \sin C = \frac{1}{2}D_1D_2$, where C = angle between two adjacent sides; D_1, D_2 = diagonals.

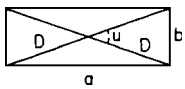

Fig. 2.1.28 Rectangle.

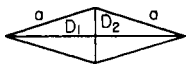

Fig. 2.1.29 Rhombus.

Parallelogram (Fig. 2.1.30) Area $= bh = ab \sin C = \frac{1}{2}D_1D_2 \sin u$, where u = angle between diagonals D_1 and D_2.

Trapezoid (Fig. 2.1.31) Area $= \frac{1}{2}(a + b)\,h$ where bases a and b are parallel.

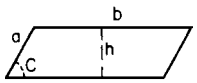

Fig. 2.1.30 Parallelogram.

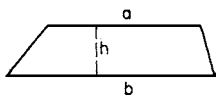

Fig. 2.1.31 Trapezoid.

Any Quadrilateral (Fig. 2.1.32) Area $= \frac{1}{2}D_1D_2 \sin u$.

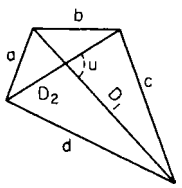

Fig. 2.1.32 Quadrilateral.

Regular Polygons n = number of sides; $v = 360°/n$ = angle subtended at center by one side; a = length of one side $= 2R \sin(v/2) = 2r \tan(v/2)$; R = radius of circumscribed circle $= 0.5\,a \csc(v/2) = r \sec(v/2)$; r = radius of inscribed circle $= R \cos(v/2) = 0.5 \cot(v/2)$; area $= 0.25\,a^2n \cot(v/2) = 0.5\,R^2n \sin(v) = r^2n \tan(v/2)$. Areas of regular polygons are tabulated in Table 1.1.3.

Circle Area $= \pi r^2 = \frac{1}{2}Cr = \frac{1}{4}Cd = \frac{1}{4}\pi d^2 = 0.785398d^2$, where r = radius, d = diameter, C = circumference $= 2\pi r = \pi d$.

Annulus (Fig. 2.1.33) Area $= \pi(R^2 - r^2) = \pi(D^2 - d^2)/4 = 2\pi R'b$, where R' = mean radius $= \frac{1}{2}(R + r)$, and $b = R - r$.

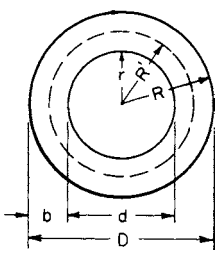

Fig. 2.1.33 Annulus.

Sector (Fig. 2.1.34) Area $= \frac{1}{2}rs = \pi r^2 A/360° = \frac{1}{2}r^2 \text{ rad } A$, where rad A = radian measure of angle A, and s = length of arc $= r$ rad A.

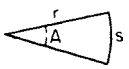

Fig. 2.1.34 Sector.

Segment (Fig. 2.1.35) Area = $\frac{1}{2}r^2(\text{rad } A - \sin A) = \frac{1}{2}[r(s - c) + ch]$, where rad A radian measure of angle A. For small arcs, $s = \frac{1}{3}(8c' - c)$, where c' = chord of half of the arc (Huygens' approximation). Areas of segments are tabulated in Tables 1.1.1 and 1.1.2.

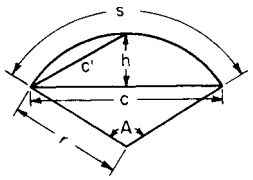

Fig. 2.1.35 Segment.

Ribbon bounded by two parallel curves (Fig. 2.1.36). If a straight line AB moves so that it is always perpendicular to the path traced by its middle point G, then the area of the ribbon or strip thus generated is equal to the length of AB times the length of the path traced by G. (It is assumed that the radius of curvature of G's path is never less than $\frac{1}{2}AB$, so that successive positions of generating line will not intersect.)

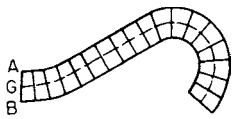

Fig. 2.1.36 Ribbon.

Ellipse (Fig. 2.1.37) Area of ellipse = πab. Area of shaded segment = $xy + ab \sin^{-1}(x/a)$. Length of perimeter of ellipse = $\pi(a + b)K$, where $K = (1 + \frac{1}{4}m^2 + \frac{1}{64}m^4 + \frac{1}{256}m^6 + \ldots)$, $m = (a - b)/(a + b)$.

For m =	0.1	0.2	0.3	0.4	0.5
K =	1.002	1.010	1.023	1.040	1.064
For m =	0.6	0.7	0.8	0.9	1.0
K =	1.092	1.127	1.168	1.216	1.273

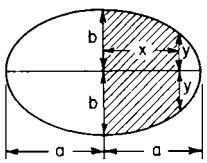

Fig. 2.1.37 Ellipse.

Hyperbola (Fig. 2.1.38) In any hyperbola, shaded area $A = ab \ln[(x/a) + (y/b)]$. In an equilateral hyperbola ($a = b$), area $A = a^2 \sinh^{-1}(y/a) = a^2 \cosh^{-1}(x/a)$. Here x and y are coordinates of point P.

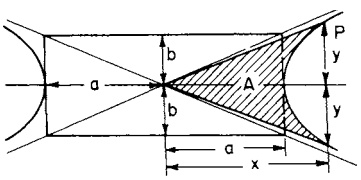

Fig. 2.1.38 Hyperbola.

For lengths and areas of **other curves** see Analytical Geometry.

Surfaces and Volumes of Solids

Regular Prism (Fig. 2.1.39) Volume = $\frac{1}{2}nrah = Bh$. Lateral area = $nah = Ph$. Here n = number of sides; B = area of base; P = perimeter of base.

Right Circular Cylinder (Fig. 2.1.40) Volume = $\pi r^2 h = Bh$. Lateral area = $2\pi rh = Ph$. Here B = area of base; P = perimeter of base.

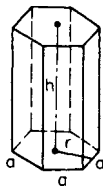

Fig. 2.1.39 Regular prism.

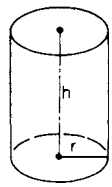

Fig. 2.1.40 Right circular cylinder.

Truncated Right Circular Cylinder (Fig. 2.1.41) Volume = $\pi r^2 h = Bh$. Lateral area = $2\pi rh = Ph$. Here h = mean height = $\frac{1}{2}(h_1 + h_2)$; B = area of base; P = perimeter of base.

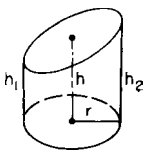

Fig. 2.1.41 Truncated right circular cylinder.

Any Prism or Cylinder (Fig. 2.1.42) Volume = $Bh = Nl$. Lateral area = Ql. Here l = length of an element or lateral edge; B = area of base; N = area of normal section; Q = perimeter of normal section.

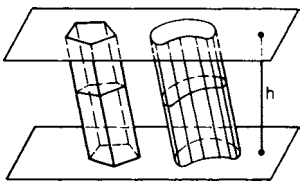

Fig. 2.1.42 Any prism or cylinder.

Special Ungula of a Right Cylinder (Fig. 2.1.43) Volume = $\frac{2}{3}r^2H$. Lateral area = $2rH$. r = radius. (Upper surface is a semiellipse.)

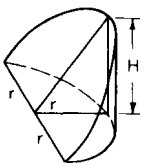

Fig. 2.1.43 Special ungula of a right circular cylinder.

Any Ungula of a right circular cylinder (Figs. 2.1.44 and 2.1.45) Volume = $H(\frac{2}{3}a^3 \pm cB)/(r \pm c) = H[a(r^2 - \frac{1}{3}a^2) \pm r^2 c \text{ rad } u]/(r \pm c)$. Lateral area = $H(2ra \pm cs)/(r \pm c) = 2rH(a \pm c \text{ rad } u)/$

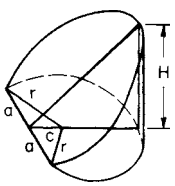

Fig. 2.1.44 Ungula of a right circular cylinder.

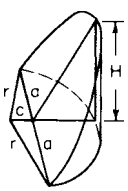

Fig. 2.1.45 Ungula of a right circular cylinder.

($r \pm c$). If base is greater (less) than a semicircle, use + (−) sign. r = radius of base; B = area of base; s = arc of base; u = half the angle subtended by arc s at center; rad u = radian measure of angle u.

Regular Pyramid (Fig. 2.1.46) Volume = ⅓ altitude × area of base = ⅙$hran$. Lateral area = ½ slant height × perimeter of base = ½san. Here r = radius of inscribed circle; a = side (of regular polygon); n = number of sides; $s = \sqrt{r^2 + h^2}$. Vertex of pyramid directly above center of base.

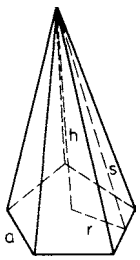

Fig. 2.1.46 Regular pyramid.

Right Circular Cone Volume = ⅓$\pi r^2 h$. Lateral area = πrs. Here r = radius of base; h = altitude; s = slant height = $\sqrt{r^2 + h^2}$.

Frustum of Regular Pyramid (Fig. 2.1.47) Volume = ⅙$hran$[1 + (a'/a) + $(a'/a)^2$]. Lateral area = slant height × half sum of perimeters of bases = slant height × perimeter of midsection = ½$sn(r + r')$. Here r,r' = radii of inscribed circles; $s = \sqrt{(r - r')^2 + h^2}$; a,a' = sides of lower and upper bases; n = number of sides.

Frustum of Right Circular Cone (Fig. 2.1.48) Volume = $\frac{1}{3}\pi r^2 h[1 + (r'/r) + (r'/r)^2] = \frac{1}{3}\pi h(r^2 + rr' + r'^2) = \frac{1}{4}\pi h[r + r')^2 + \frac{1}{3}(r - r')^2]$. Lateral area = $\pi s(r + r')$; $s = \sqrt{(r - r')^2 + h^2}$.

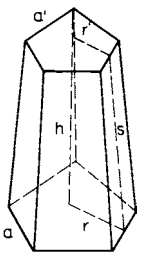

Fig. 2.1.47 Frustum of a regular pyramid.

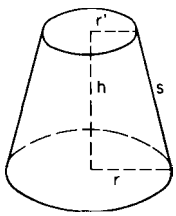

Fig. 2.1.48 Frustum of a right circular cone.

Any Pyramid or Cone Volume = ⅓Bh. B = area of base; h = perpendicular distance from vertex to plane in which base lies.

Any Pyramidal or Conical Frustum (Fig. 2.1.49) Volume = $\frac{1}{3}h(B + \sqrt{BB'} + B') = \frac{1}{3}hB[1 + (P'/P) + (P'/P)^2]$. Here B, B' = areas of lower and upper bases; P, P' = perimeters of lower and upper bases.

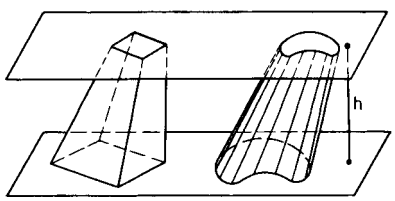

Fig. 2.1.49 Pyramidal frustum and conical frustum.

Sphere Volume = $V = \frac{4}{3}\pi r^3 = 4.188790r^3 = \frac{1}{6}\pi d^3 = \frac{2}{3}$ volume of circumscribed cylinder. Area = $A = 4\pi r^2$ = four great circles = πd^2 = lateral area of circumscribed cylinder. Here r = radius; $d = 2r$ = diameter = $\sqrt[3]{6V/\pi} = \sqrt{A/\pi}$.

Hollow Sphere or spherical shell. Volume = $\frac{4}{3}\pi(R^3 - r^3) = \frac{1}{6}\pi(D^3 - d^3) = 4\pi R_1^2 t + \frac{1}{3}\pi t^3$. Here R, r = outer and inner radii; D,d = outer and inner diameters; t = thickness = $R - r$; R_1 = mean radius = ½$(R + r)$.

Any Spherical Segment. Zone (Fig. 2.1.50) Volume = $\frac{1}{6}\pi h(3a^2 + 3a_1^2 + h^2)$. Lateral area (zone) = $2\pi rh$. Here r = radius of sphere. If the inscribed frustum of a cone is removed from the spherical segment, the volume remaining is ⅙πhc^2, where c = slant height of frustum = $\sqrt{h^2 + (a - a_1)^2}$.

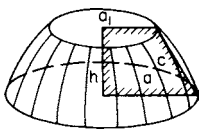

Fig. 2.1.50 Any spherical segment.

Spherical Segment of One Base. Zone (spherical "cap" of Fig. 2.1.51) Volume = $\frac{1}{6}\pi h(3a^2 + h^2) = \frac{1}{3}\pi h^2(3r - h)$. Lateral area (of zone) = $2\pi rh = \pi(a^2 + h^2)$.

NOTE. $a^2 = h(2r - h)$, where r = radius of sphere.

Spherical Sector (Fig. 2.1.51) Volume = ⅓r × area of cap = $\frac{2}{3}\pi r^2 h$. Total area = area of cap + area of cone = $2\pi rh + \pi ra$.

NOTE. $a^2 = h(2r - h)$.

Spherical Wedge bounded by two plane semicircles and a **lune** (Fig. 2.1.52). Volume of wedge ÷ volume of sphere = u/360°. Area of lune ÷ area of sphere = u/360°. u = dihedral angle of the wedge.

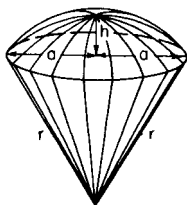

Fig. 2.1.51 Spherical sector.

Fig. 2.1.52 Spherical wedge.

Solid Angles Any portion of a spherical surface subtends what is called a **solid angle** at the center of the sphere. If the area of the given portion of spherical surface is equal to the square of the radius, the subtended solid angle is called a **steradian,** and this is commonly taken as the unit. The entire solid angle about the center is equal to 4π steradians. A so-called "solid right angle" is the solid angle subtended by a quadrantal (or trirectangular) spherical triangle, and a "spherical degree" (now little used) is a solid angle equal to 1/90 of a solid right angle. Hence 720 spherical degrees = 1 steregon, or π steradians = 180 spherical degrees. If u = the angle which an element of a cone makes with its axis, then the solid angle of the cone contains $2\pi(1 - \cos u)$ steradians.

Regular Polyhedra A = area of surface; V = volume; a = edge.

Name of solid	Bounded by	A/a^2	V/a^3
Tetrahedron	4 triangles	1.7321	0.1179
Cube	6 squares	6.0000	1.0000
Octahedron	8 triangles	3.4641	0.4714
Dodecahedron	12 pentagons	20.6457	7.6631
Icosahedron	20 triangles	8.6603	2.1917

Ellipsoid (Fig. 2.1.53) Volume = $\frac{4}{3}\pi abc$, where a, b, c = semiaxes.

Torus, or Anchor Ring (Fig. 2.1.54) Volume = $2\pi^2 cr^2$. Area = $4\pi^2 cr$.

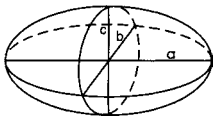

Fig. 2.1.53 Ellipsoid.

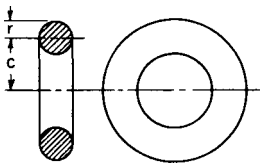

Fig. 2.1.54 Torus.

Volume of a Solid of Revolution (solid generated by rotating an area bounded above by $f(x)$ around the x axis)

$$V = \pi \int_a^b |f(x)|^2 \, dx$$

Area of a Surface of Revolution

$$A = 2\pi \int_a^b y\sqrt{1 + (dy/dx)^2}\, dx$$

Length of Arc of a Plane Curve $y = f(x)$ between values $x = a$ and $x = b$. $s = \int_a^b \sqrt{1 + (dy/dx)^2}\, dx$. If $x = f(t)$ and $y = g(t)$, for $a < t < b$, then

$$s = \int_a^b \sqrt{(dx/dt)^2 + (dy/dt)^2}\, dt$$

PERMUTATIONS AND COMBINATIONS

The product (1)(2)(3) . . . (n) is written $n!$ and is read "n factorial." By convention, $0! = 1$, and $n!$ is not defined for negative integers.

For large values of n, $n!$ may be approximated by Stirling's formula:

$$n! \approx 2.50663 n^{n+.5} e^{-n}$$

The **binomial coefficient** $C(n, k)$, also written $\binom{n}{k}$, is defined as:

$$C(n, k) \frac{n!}{k!(n-k)!}$$

$C(n, k)$ is read "n choose k" or as "binomial coefficient n-k."

Binomial coefficients have the following properties:

1. $C(n, 0) = C(n, n) = 1$
2. $C(n, 1) = C(n, n-1) = n$
3. $C(n+1, k) = C(n, k) + C(n, k-1)$
4. $C(n, k) = C(n, n-k)$

Binomial coefficients are tabulated in Sec. 1.

Binomial Theorem

If n is a positive integer, then

$$(a+b)^n = \sum_{k=0}^{n} C(n, k) a^k b^{n-k}$$

EXAMPLE. The third term of $(2x + 3)^7$ is $C(7, 4)(2x)^{7-4}3^4 = [7!/(4!3!)](2x)^3 3^4 = (35)(8x^3)(81) = 22680x^3$.

Combinations $C(n, k)$ gives the number of ways k distinct objects can be chosen from a set of n elements. This is the number of k-element subsets of a set of n elements.

EXAMPLE. The set of four elements (a, b, c, d) has $C(4, 2) = 6$ two-element subsets, $\{a, b\}$, $\{a, c\}$, $\{a, d\}$, $\{b, c\}$, $\{b, d\}$, and $\{c, d\}$. (Note that $\{a, c\}$ is the same set as $\{c, a\}$.)

Permutations The number of ways k objects may be arranged from a set of n elements is given by

$$P(n, k) = \frac{n!}{(n-k)!}$$

EXAMPLE. Two elements from the set (a, b, c, d) may be arranged in $P(4, 2) = 12$ ways: ab, ac, ad, ba, bc, bd, ca, cb, cd, da, db, and dc. Note that ac is a different arrangement than ca.

Permutations and combinations are examined in detail in most texts on probability and statistics and on discrete mathematics.

If an event can occur in s ways and can fail to occur in f ways, and if all ways are equally likely, then the probability of the event's occurring is $p = s/(s+f)$, and the probability of failure is $q = f/(s+f) = 1 - p$.

The set of all possible outcomes of an experiment is called the **sample space,** denoted S. Let n be the number of outcomes in the sample set. A subset A of the sample space is called an **event.** The number of outcomes in A is s. Therefore $P(A) = s/n$. The probability that A does not occur is $P(\bar{A}) = q = 1 - p$.

Always $0 \le p \le 1$ and $P(S) = 1$.

If two events cannot occur simultaneously, then $A \cap B = \varnothing$, and A and B are said to be **mutually exclusive.** Then $P(A \cup B) = P(A) + P(B)$. Otherwise, $P(A \cup B) = P(A) + P(B) - P(A \cap B)$.

Events A and B are **independent** if $P(A \cap B) = P(A)P(B)$.

If E is an event and if $P(E) > 0$, then the probability that A occurs once E has already occurred is called the "conditional probability of A given E," written $P(A|E)$ and defined as

$$P(A|E) = P(A \cap E)/P(E)$$

A and E are independent if $P(A|E) = P(A)$.

If the outcomes in a sample space X are all numbers, then X, together with the probabilities of the outcomes, is called a **random variable.** If x_i is an outcome, then $p_i = P(x_i)$.

The **expected value** of a random variable is

$$E(X) = \Sigma\, e_i p_i$$

The **variance** of X is

$$V(X) = \Sigma[x_i - E(X)]^2 p_i$$

The **standard deviation** is

$$S(X) = \sqrt{[V(X)]}$$

The Binomial, or Bernoulli, Distribution If an experiment is repeated n times and the probability of a success on any trial is p, then the probability of k successes among those n trials is

$$f(n, k, p) = C(n, k) p^k q^{n-k}$$

Geometric Distribution If an experiment is repeated until it finally succeeds, let x be the number of failures observed before the first success. Let p be the probability of success on any trial and let $q = 1 - p$. Then

$$P(x = k) = q^k \cdot p$$

Uniform Distribution If the random variable x assumes the values 1, 2, . . . , n, with equal probabilities, then the distribution is uniform, and

$$P(x = k) = \frac{1}{n}$$

Hypergeometric Distribution—Sampling without Replacement If a finite population of N elements contains x successes and if n items are selected randomly without replacement, then the probability that k

successes will occur among those n samples is

$$h(x; N, n, k) = \frac{C(k, x)C(N - k, n - x)}{C(N, n)}$$

For large values of N, the hypergeometric distribution approaches the binomial distribution, so

$$h(x; N, n, k) \approx f\left(n, k, \frac{x}{N}\right)$$

Poisson Distribution If the average number of successes which occur in a given fixed time interval is m, then let x be the number of successes observed in that time interval. The probability that $x = k$ is

$$p(k, m) = \frac{e^{-m}m^x}{x!} \qquad \text{where } e = 2.71828\ldots$$

Negative Binomial Distribution If repeated independent trials have probability of success p, then let x be the trial number upon which success number n occurs. Then the probability that $x = k$ is

$$b^*(k; n, p) = C(k - 1, n - 1)p^n q^{k-n}$$

The expected values and variances of these distributions are summarized in the following table:

Distribution	$E(X)$	$V(X)$
Uniform	$(n + 1)/2$	$(n^2 - 1)/12$
Binomial	np	npq
Hypergeometric	nk/N	$[nk(N - n)(1 - k/N)]/[N(N - 1)]$
Poisson	m	m
Geometric	q/p	q/p^2
Negative binomial	nq/p	nq/p^2

LINEAR ALGEBRA

Using linear algebra, it is often possible to express in a single equation a set of relations that would otherwise require several equations. Similarly, it is possible to replace many calculations involving several variables with a few calculations involving vectors and matrices. In general, the equations to which the techniques of linear algebra apply must be linear equations; they can involve no polynomial, exponential, or trigonometric terms.

Vectors

A **row vector v** is a list of numbers written in a row, usually enclosed by parentheses.

$$\mathbf{v} = (v_1, v_2, \ldots, v_n)$$

A **column vector u** is a list of numbers written in a column:

$$\mathbf{u} = \begin{pmatrix} u_1 \\ u_2 \\ \cdot \\ \cdot \\ \cdot \\ u_n \end{pmatrix}$$

The numbers u_i and v_i may be real or complex, or they may even be variables or functions.

A vector is sometimes called an **ordered *n*-tuple.** In the case where $n = 2$, it may be called an **ordered pair.**

The numbers v_i are called **components** or **coordinates** of the vector **v**. The number n is called the **dimension** of **v**.

Two-dimensional vectors correspond with points in the plane, where v_1 is the x coordinate and v_2 is the y coordinate of the point **v**. Two-dimensional vectors also correspond with complex numbers, where $z = v_1 + iv_2$.

Three-dimensional vectors correspond to points in space, where v_1, v_2, and v_3 are the x, y, and z coordinates of the point, respectively.

Two- and three-dimensional vectors may be thought of as having a direction and a magnitude. See the section "Analytical Geometry."

Two vectors **u** and **v** are equal if:

1. **u** and **v** are the same type (either row or column).
2. **u** and **v** have the same dimension.
3. Corresponding components are equal; that is, $u_i = v_i$ for $i = 1, 2, \ldots, n$.

Note that the row vectors

$$\mathbf{u} = (1, 2, 3) \qquad \text{and} \qquad \mathbf{v} = (3, 2, 1)$$

are not equal since the components are not in the same order. Also,

$$\mathbf{u} = (1, 2, 3) \qquad \text{and} \qquad \mathbf{v} = \begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix}$$

are not equal since **u** is a row vector and **v** is a column vector.

Vector Transpose If **u** is a row vector, then the **transpose** of **u**, written $\mathbf{u}^T$, is the column vector with the same components in the same order as **u**. Similarly, the transpose of a column vector is the row vector with the same components in the same order. Note that $(\mathbf{u}^T)^T = \mathbf{u}$.

Vector Addition If **u** and **v** are vectors of the same type and the same dimension, then the sum of **u** and **v**, written $\mathbf{u} + \mathbf{v}$, is the vector obtained by adding corresponding components. In the case of row vectors,

$$\mathbf{u} + \mathbf{v} = (u_1 + v_1, u_2 + v_2, \ldots, u_n + v_n)$$

Scalar Multiplication If a is a number and **u** is a vector, then the **scalar product** $a\mathbf{u}$ is the vector obtained by multiplying each component of **u** by a.

$$a\mathbf{u} = (au_1, au_2, \ldots, au_n)$$

A number by which a vector is multiplied is called a **scalar.**

The **negative** of vector **u** is written $-\mathbf{u}$, and

$$-\mathbf{u} = -1\mathbf{u}$$

The **zero vector** is the vector with all its components equal to zero.

Arithmetic Properties of Vectors If **u, v,** and **w** are vectors of the same type and dimensions, and if a and b are scalars, then vector addition and scalar multiplication obey the following seven rules, known as the *properties of a vector space:*

1. $(\mathbf{u} + \mathbf{v}) + \mathbf{w} = \mathbf{u} + (\mathbf{v} + \mathbf{w})$	associative law
2. $\mathbf{u} + \mathbf{v} = \mathbf{v} + \mathbf{u}$	commutative law
3. $\mathbf{u} + \mathbf{0} = \mathbf{u}$	additive identity
4. $\mathbf{u} + (-\mathbf{u}) = \mathbf{0}$	additive inverse
5. $a(\mathbf{u} + \mathbf{v}) = a\mathbf{u} + a\mathbf{v}$	distributive law
6. $(ab)\mathbf{u} = a(b\mathbf{u})$	associative law of multiplication
7. $1\mathbf{u} = \mathbf{u}$	multiplicative identity

Inner Product or Dot Product If **u** and **v** are vectors of the same type and dimension, then their **inner product** or **dot product,** written **uv** or $\mathbf{u} \cdot \mathbf{v}$, is the scalar

$$\mathbf{uv} = u_1v_1 + u_2v_2 + \cdots + u_nv_n$$

Vectors **u** and **v** are **perpendicular** or **orthogonal** if $\mathbf{uv} = 0$.

Magnitude There are two equivalent ways to define the magnitude of a vector **u**, written $|\mathbf{u}|$ or $\|\mathbf{u}\|$.

$$|\mathbf{u}| = \sqrt{(\mathbf{u} \cdot \mathbf{u})}$$

or

$$|\mathbf{u}| = \sqrt{(u_1^2 + u_2^2 + \cdots + u_n^2)}$$

Cross Product or Outer Product If **u** and **v** are three-dimensional vectors, then they have a **cross product,** also called **outer product** or **vector product.**

$$\mathbf{u} \times \mathbf{v} = (u_2v_3 - u_3v_2, v_1u_3 - v_3u_1, u_1v_2 - u_2v_1)$$

The cross product $\mathbf{u} \times \mathbf{v}$ is a three-dimensional vector that is perpendicular to both $\mathbf{u}$ and $\mathbf{v}$. The cross product is not commutative. In fact,

$$\mathbf{u} \times \mathbf{v} = -\mathbf{v} \times \mathbf{u}$$

Cross product and inner product have two properties involving trigonometric functions. If θ is the angle between vectors $\mathbf{u}$ and $\mathbf{v}$, then

$$\mathbf{uv} = |\mathbf{u}||\mathbf{v}| \cos\theta \quad \text{and} \quad |\mathbf{u} \times \mathbf{v}| = |\mathbf{u}||\mathbf{v}| \sin\theta$$

Matrices

A **matrix** is a rectangular array of numbers. A matrix A with m rows and n columns may be written

$$A = \begin{pmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \cdots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \cdots & a_{3n} \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ a_{m1} & a_{m2} & a_{m3} & \cdots & a_{mn} \end{pmatrix}$$

The numbers a_{ij} are called the **entries** of the matrix. The first subscript i identifies the row of the entry, and the second subscript j identifies the column.

Matrices are denoted either by capital letters, A, B, etc., or by writing the general entry in parentheses, (a_{ij}).

The number of rows and the number of columns together define the dimensions of the matrix. The matrix A is an $m \times n$ matrix, read "m by n."

A row vector may be considered to be a $1 \times n$ matrix, and a column vector may be considered as a $n \times 1$ matrix.

The rows of a matrix are sometimes considered as row vectors, and the columns may be considered as column vectors.

If a matrix has the same number of rows as columns, the matrix is called a **square matrix.**

In a square matrix, the entries a_{ii}, where the row index is the same as the column index, are called the diagonal entries.

If a matrix has all its entries equal to zero, it is called a **zero matrix.**

If a square matrix has all its entries equal to zero except its diagonal entries, it is called a **diagonal matrix.**

The diagonal matrix with all its diagonal entries equal to 1 is called the **identity matrix,** and is denoted I, or $I_{n\times n}$ if it is important to emphasize the dimensions of the matrix. The 2×2 and 3×3 identity matrices are:

$$I_{2\times 2} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \qquad I_{3\times 3} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

The entries of a square matrix a_{ij} where $i > j$ are said to be below the diagonal. Similarly, those where $i < j$ are said to be above the diagonal.

A square matrix with all entries below (resp. above) the diagonal equal to zero is called *upper-triangular* (resp. *lower-triangular*).

Matrix Addition Matrices A and B may be added only if they have the same dimensions. Then the sum $C = A + B$ is defined by

$$c_{ij} = a_{ij} + b_{ij}$$

That is, corresponding entries of the matrices are added together, just as with vectors. Similarly, matrices may be multiplied by scalars.

Matrix Multiplication Matrices A and B may be multiplied only if the number of columns in A equals the number of rows of B. If A is an $m \times n$ matrix and B is an $n \times p$ matrix, then the product $C = AB$ is an $m \times p$ matrix, defined as follows:

$$\begin{aligned} c_{ij} &= a_{i1}b_{1j} + a_{i2}b_{2j} + \cdots + a_{in}b_{nj} \\ &= \sum_{k=1}^{n} a_{ik}b_{kj} \end{aligned}$$

The entry c_{ij} may also be defined as the dot product of row i of A with the transpose of column j of B.

EXAMPLE. $\begin{pmatrix} 1 & 2 \\ 5 & 6 \end{pmatrix} \begin{pmatrix} 3 & 4 \\ 7 & 8 \end{pmatrix} =$

$$\begin{pmatrix} 1\times 3 + 2\times 7 & 1\times 4 + 2\times 8 \\ 5\times 3 + 6\times 7 & 5\times 4 + 6\times 8 \end{pmatrix} = \begin{pmatrix} 17 & 20 \\ 57 & 68 \end{pmatrix}$$

Matrix multiplication is not commutative. Even if A and B are both square, it is hardly ever true that $AB = BA$. Matrix multiplication does have the following properties:

1. $(AB)C = A(BC)$ — associative law
2. $A(B + C) = AB + AC$
3. $(B + C)A = BA + CA$

— distributive laws

If A is square, then also

4. $AI = IA = A$ — multiplicative identity

If A is square, then powers of A, AA, and AAA are denoted A^2 and A^3, respectively.

The transpose of a matrix A, written A^T, is obtained by writing the rows of A as columns. If A is $m \times n$, then A^T is $n \times m$.

EXAMPLE. $\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{pmatrix}^T = \begin{pmatrix} 1 & 4 \\ 2 & 5 \\ 3 & 6 \end{pmatrix}$

The transpose has the following properties:

1. $(A^T)^T = A$
2. $(A + B)^T = A^T + B^T$
3. $(AB)^T = B^T A^T$

Note that in property 3, the order of multiplication is reversed.

If $A^T = A$, then A is called *symmetric.*

Linear Equations

A linear equation in two variables is of the form

$$a_1x_1 + a_2x_2 = b \qquad \text{or} \qquad a_1x + a_2y = b$$

depending on whether the variables are named x_1 and x_2 or x and y.

In n variables, such an equation has the form

$$a_1x_1 + a_2x_2 + \cdots a_nx_n = b$$

Such equations describe lines and planes. Often it is necessary to solve several such equations simultaneously. A set of m linear equations in n variables is called an $m \times n$ system of simultaneous linear equations.

Systems with Two Variables

1 × 2 Systems An equation of the form

$$a_1x + a_2y = b$$

has infinitely many solutions which form a straight line in the xy plane. That line has slope $-a_1/a_2$ and y intercept b/a_2.

2 × 2 Systems A 2×2 system has the form

$$a_{11}x + a_{12}y = b_1 \qquad a_{21}x + a_{22}y = b_2$$

Solutions to such systems do not always exist.

CASE 1. The system has exactly one solution (Fig. 2.1.55*a*). The lines corresponding to the equations intersect at a single point. This occurs whenever the two lines have different slopes, so they are not

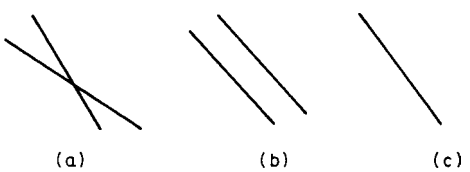

Fig. 2.1.55 Lines corresponding to linear equations. (*a*) One solution; (*b*) no solutions; (*c*) infinitely many solutions.

parallel. In this case,

$$\frac{a_{11}}{a_{21}} \neq \frac{a_{12}}{a_{22}} \qquad \text{so} \qquad a_{11}a_{22} - a_{21}a_{12} \neq 0$$

CASE 2. The system has no solutions (Fig. 2.1.55*b*). This occurs whenever the two lines have the same slope and different y intercepts, so they are parallel. In this case,

$$\frac{a_{11}}{a_{21}} = \frac{a_{12}}{a_{22}}$$

CASE 3. The system has infinitely many solutions (Fig. 2.1.55*c*). This occurs whenever the two lines coincide. They have the same slope and y intercept. In this case,

$$\frac{a_{11}}{a_{21}} = \frac{a_{12}}{a_{22}} = \frac{b_1}{b_2}$$

The value $a_{11}\,a_{22} - a_{21}\,a_{12}$ is called the **determinant** of the system. A larger $n \times n$ system also has a determinant (see below). A system has exactly one solution when its determinant is not zero.

3 × 2 Systems Any system with more equations than variables is called **overdetermined.** The only case in which a 3×2 system has exactly one solution is when one of the equations can be derived from the other two.

One basic way to solve such a system is to treat any two equations as a 2×2 system and see if the solution to that subsystem of equations is also a solution to the third equation.

Matrix Form for Systems of Equations The 2×2 system of linear equations

$$a_{11}x_1 + a_{12}x_2 = b_1 \qquad a_{21}x_1 + a_{22}x_2 = b_2$$

may be written as a matrix equation as follows:

$$\begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} b_1 \\ b_2 \end{pmatrix}$$

or as

$$A\mathbf{x} = \mathbf{b}$$

where A is the 2×2 matrix and $\mathbf{x}$ and $\mathbf{b}$ are two-dimensional column vectors. Then, the determinant of A, written det A or $|A|$, is the same as the determinant of the 2×2 system:

$$\det A = a_{11}a_{22} - a_{21}a_{12}$$

In general, any $m \times n$ system of simultaneous linear equations may be written as

$$A\mathbf{x} = \mathbf{b}$$

where A is an $m \times n$ matrix, $\mathbf{x}$ is an n-dimensional column vector, and $\mathbf{b}$ is an m-dimensional column vector.

An $n \times n$ (square) system of simultaneous linear equations has exactly one solution whenever its determinant is not zero. Then the system and the matrix A are called **nonsingular.** If the determinant is zero, the system is called **singular.**

Elementary Row Operations on a Matrix There are three operations on a matrix which change the matrix:

1. Multiply each entry in row i by a scalar k (not zero).
2. Interchange row i with row j.
3. Add row i to row j.

Similarly, there are three elementary column operations.

The elementary row operations have the following effects on $|A|$:

1. Multiplying a row (or column) by k multiplies $|A|$ by k.
2. Interchanging two rows (or columns) multiplies $|A|$ by -1.
3. Adding one row (or column) to another does not change $|A|$.

Pivoting, or Reducing, a Column The process of changing the ij entry of a matrix to 1 and changing the rest of column j to zero, by using elementary row operations, is known as **reducing** column j or as **pivoting** on the ij entry. Combining pivoting, the properties of the elementary row operations, and the fact:

$$|I_{n\times n}| = 1$$

provides a technique for finding the determinant of $n \times n$ matrices.

EXAMPLE. Find $|A|$ where

$$A = \begin{pmatrix} 1 & 2 & -4 \\ 5 & -3 & -7 \\ 3 & -2 & 3 \end{pmatrix}$$

First, pivot on the entry in row 1, column 1, in this case, the 1.

Multiplying row 1 by -5, then adding row 1 to row 2, we first multiply the determinant by -5, then do not change it:

$$-5|A| = \begin{vmatrix} -5 & -10 & 20 \\ 5 & -3 & -7 \\ 3 & -2 & 3 \end{vmatrix} = \begin{vmatrix} -5 & -10 & 20 \\ 0 & -13 & 13 \\ 3 & -2 & 3 \end{vmatrix}$$

Next, multiply row 1 by $^3/_5$ and add row 1 to row 3:

$$-3|A| = \begin{vmatrix} -3 & -6 & 12 \\ 0 & -13 & 13 \\ 3 & -2 & 3 \end{vmatrix} = \begin{vmatrix} -3 & -6 & 12 \\ 0 & -13 & 13 \\ 0 & -8 & 15 \end{vmatrix}$$

Next, divide row 1 by -3:

$$|A| = \begin{vmatrix} 1 & 2 & -4 \\ 0 & -13 & 13 \\ 0 & -8 & 15 \end{vmatrix}$$

Next, pivot on the entry in row 2, column 2. Multiplying row 2 by $-^8/_{13}$ and then adding row 2 to row 3, we get:

$$-\frac{8}{13}|A| = \begin{vmatrix} 1 & 2 & -4 \\ 0 & 8 & -8 \\ 0 & -8 & 15 \end{vmatrix} = \begin{vmatrix} 1 & 2 & -4 \\ 0 & 8 & -8 \\ 0 & 0 & 7 \end{vmatrix}$$

Next, divide row 2 by $-^8/_{13}$.

$$|A| = \begin{vmatrix} 1 & 2 & -4 \\ 0 & -13 & 13 \\ 0 & 0 & 7 \end{vmatrix}$$

The determinant of a triangular matrix is the product of its diagonal elements, in this case -91.

Inverses Whenever $|A|$ is not zero, that is, whenever A is nonsingular, then there is another $n \times n$ matrix, denoted A^{-1}, read "A inverse" with the property

$$AA^{-1} = A^{-1}A = I_{n\times n}$$

Then the $n \times n$ system of equations

$$A\mathbf{x} = \mathbf{b}$$

can be solved by multiplying both sides by A^{-1}, so

$$\mathbf{x} = I_{n\times n}\mathbf{x} = A^{-1}A\mathbf{x} = A^{-1}\mathbf{b}$$

so

$$\mathbf{x} = A^{-1}\mathbf{b}$$

The matrix A^{-1} may be found as follows:

1. Make a $n \times 2n$ matrix, with the first n columns the matrix A and the last n columns the identity matrix $I_{n\times n}$.
2. Pivot on each of the diagonal entries of this matrix, one after another, using the elementary row operations.
3. After pivoting n times, the matrix will have in the first n columns the identity matrix, and the last n columns will be the matrix A^{-1}.

EXAMPLE. Solve the system

$$\begin{aligned} x_1 + 2x_2 - 4x_3 &= -4 \\ 5x_1 - 3x_2 - 7x_3 &= 6 \\ 3x_1 - 2x_2 + 3x_3 &= 11 \end{aligned}$$

We must invert the matrix

$$A = \begin{pmatrix} 1 & 2 & -4 \\ 5 & -3 & -7 \\ 3 & -2 & 3 \end{pmatrix}$$

This is the same matrix used in the determinant example above. Adjoin the identity matrix to make a 3×6 matrix

$$\begin{pmatrix} 1 & 2 & -4 & 1 & 0 & 0 \\ 5 & -3 & -7 & 0 & 1 & 0 \\ 3 & -2 & 3 & 0 & 0 & 1 \end{pmatrix}$$

Perform the elementary row operations in exactly the same order as in the determinant example.

STEP 1. Pivot on row 1, column 1.

$$\begin{pmatrix} 1 & 2 & -4 & 1 & 0 & 0 \\ 0 & -13 & 13 & -5 & 1 & 0 \\ 0 & -8 & 15 & -3 & 0 & 1 \end{pmatrix}$$

STEP 2. Pivot on row 2, column 2.

$$\begin{pmatrix} 1 & 0 & -2 & 3/13 & 2/13 & 0 \\ 0 & 1 & -1 & 5/13 & -1/13 & 0 \\ 0 & 0 & 7 & 1/13 & -8/13 & 1 \end{pmatrix}$$

STEP 3. Pivot on row 3, column 3.

$$\begin{pmatrix} 1 & 0 & 0 & 23/91 & -2/91 & 26/91 \\ 0 & 1 & 0 & 36/91 & -15/91 & 13/91 \\ 0 & 0 & 1 & 1/91 & -8/91 & 13/91 \end{pmatrix}$$

Now, the inverse matrix appears on the right. To solve the equation,

$$\mathbf{x} = A^{-1}\mathbf{b}$$

so,

$$\mathbf{x} = \begin{pmatrix} 23/91 & -2/91 & 26/91 \\ 36/91 & -15/91 & 13/91 \\ 1/91 & -8/91 & 13/91 \end{pmatrix} \begin{pmatrix} -4 \\ 6 \\ 11 \end{pmatrix}$$

$$= \begin{pmatrix} (-4 \times 23 + 6 \times -2 + 11 \times 26)/91 \\ (-4 \times 36 + 6 \times -15 + 11 \times 13)/91 \\ (-4 \times 1 + 6 \times -8 + 11 \times 13)/91 \end{pmatrix} = \begin{pmatrix} 2 \\ -1 \\ 1 \end{pmatrix}$$

The solution to the system is then

$$x_1 = 2 \qquad x_2 = -1 \qquad x_3 = 1$$

Special Matrices If A is a matrix of complex numbers, then it is possible to take the complex conjugate a_{ij}^* of each entry, a_{ij}. This is called the **conjugate** of A and is denoted A^*.

1. If $a_{ij} = a_{ji}$, then A is **symmetric.**
2. If $a_{ij} = -a_{ji}$, then A is **skew** or **antisymmetric.**
3. If $A^T = A^{-1}$, then A is **orthogonal.**
4. If $A = A^{-1}$, then A is **involutory.**
5. If $A = A^*$, then A is **hermitian.**
6. If $A = -A^*$, then A is **skew hermitian.**
7. If $A^{-1} = A^*$, then A is **unitary.**

Eigenvalues and Eigenvectors If A is a square matrix and x is a variable, then the matrix $B = A - xI$ is the **characteristic matrix,** or **eigenmatrix,** of A. The determinant $|A - xI|$ is a polynomial of degree n, called the **characteristic polynomial** of A. The roots of this polynomial, x_1, $x_2, \ldots, x_n$, are the **eigenvalues** of A.

Note that some sources define the characteristic matrix as $xI - A$. If n is odd, then this multiplies the characteristic equation by -1, but the eigenvalues are not changed.

EXAMPLE.

$$A = \begin{vmatrix} -2 & 5 \\ 2 & 1 \end{vmatrix} \qquad B = \begin{vmatrix} -2 - x & 5 \\ 2 & 1 - x \end{vmatrix}$$

Then the characteristic polynomial is

$$\begin{aligned} |B| &= (-2 - x)(1 - x) - (2)(5) \\ &= x^2 + x - 2 - 10 \\ &= x^2 + x - 12 \\ &= (x + 4)(x - 3) \end{aligned}$$

The eigenvalues are -4 and $+3$.

A nonzero vector $\mathbf{v}$ satisfying

$$(A - x_i I)\mathbf{v} = \mathbf{0}$$

is called an **eigenvector** of A associated with the eigenvalue x_i. Eigenvectors have the special property

$$A\mathbf{v} = x_i\mathbf{v}$$

Any multiple of an eigenvector is also an eigenvector.

A matrix is nonsingular when none of its eigenvalues are zero.

Rank and Nullity It is possible that the product of a nonzero matrix A and a nonzero vector $\mathbf{v}$ is zero. This cannot happen if A is nonsingular.

The set of all vectors which become zero when multiplied by A is called the **kernel** of A. The **nullity** of A is the dimension of the kernel. It is a measure of how singular a matrix is.

If A is an $m \times n$ matrix, then the **rank** of A is defined as n − nullity. Rank is at most m.

The technique of pivoting is useful in finding the rank of a matrix. The procedure is as follows:

1. Pivot on each diagonal entry in the matrix, starting with a_{11}.
2. If a row becomes all zero, exchange it with other rows to move it to the bottom of the matrix.
3. If a diagonal entry is zero but the row is not all zero, exchange the column containing the entry with a column to the right not containing a zero in that row.

When the procedure can be carried no further, the nullity is the number of rows of zeros in the matrix.

EXAMPLE. Find the rank and nullity of the 3×2 matrix:

$$\begin{pmatrix} 1 & 1 \\ 2 & 1 \\ 4 & 1 \end{pmatrix}$$

Pivoting on row 1, column 1, yields

$$\begin{pmatrix} 1 & 0 \\ 0 & -1 \\ 0 & -3 \end{pmatrix}$$

Pivoting on row 2, column 2, yields

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{pmatrix}$$

Nullity is therefore 1. Rank is $3 - 1 = 2$.

If the rank of a matrix is n, so that

$$\text{Rank} + \text{nullity} = m$$

the matrix is said to be full rank.

TRIGONOMETRY

Formal Trigonometry

Angles or Rotations An **angle** is generated by the rotation of a ray, as Ox, about a fixed point O in the plane. Every angle has an **initial line** (OA) from which the rotation started (Fig. 2.1.56), and a **terminal line** (OB) where it stopped; and the counterclockwise direction of rotation is taken as positive. Since the rotating ray may revolve as often as desired, angles of any magnitude, positive or negative, may be obtained. Two angles are **congruent** if they may be superimposed so that their initial lines coincide and their terminal lines coincide; i.e., two congruent angles are either equal or differ by some multiple of 360°. Two angles are **complementary** if their sum is 90°; **supplementary** if their sum is 180°.

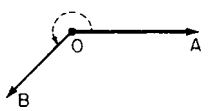

Fig. 2.1.56 Angle.

(The acute angles of a right-angled triangle are complementary.) If the initial line is placed so that it runs horizontally to the right, as in Fig. 2.1.57, then the angle is said to be an angle in the 1st, 2nd, 3rd, or 4th **quadrant** according as the terminal line lies across the region marked I, II, III, or IV.

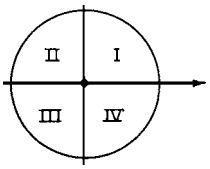

Fig. 2.1.57 Circle showing quadrants.

Units of Angular Measurement

1. *Sexagesimal measure.* (360 degrees = 1 revolution.) Denoted on many calculators by DEG. 1 degree = 1° = 1/90 of a right angle. The degree is usually divided into 60 equal parts called minutes (′), and each minute into 60 equal parts called seconds (″); while the second is subdivided decimally. But for many purposes it is more convenient to divide the degree itself into decimal parts, thus avoiding the use of minutes and seconds.

2. *Centesimal measure.* Used chiefly in France. Denoted on calculators by GRAD. (400 grades = 1 revolution.) 1 grade = 1/100 of a right angle. The grade is always divided decimally, the following terms being sometimes used: 1 "centesimal minute" = 1/100 of a grade; 1 "centesimal second" = 1/100 of a centesimal minute. In reading Continental books it is important to notice carefully which system is employed.

3. *Radian, or circular, measure.* (π radians = 180 degrees.) Denoted by RAD. 1 radian = the angle subtended by an arc whose length is equal to the length of the radius. The radian is constantly used in higher mathematics and in mechanics, and is always divided decimally. Many theorems in calculus assume that angles are being measured in radians, not degrees, and are not true without that assumption.

$$\begin{aligned} 1 \text{ radian} &= 57°.30 - = 57°.2957795131 \\ &= 57°17'44''.806247 = 180°/\pi \\ 1° &= 0.01745\ldots \text{ radian} = 0.01745\ 32925 \text{ radian} \\ 1' &= 0.00029\ 08882 \text{ radian} \\ 1'' &= 0.00000\ 48481 \text{ radian} \end{aligned}$$

Table 2.1.2 Signs of the Trigonometric Functions

If x is in quadrant	I	II	III	IV
sin x and csc x are	+	+	−	−
cos x and sec x are	+	−	−	+
tan x and cot x are	+	−	+	−

Definitions of the Trigonometric Functions Let x be any angle whose initial line is OA and terminal line OP (see Fig. 2.1.58). Drop a perpendicular from P on OA or OA produced. In the right triangle OMP, the three sides are MP = "side opposite" O (positive if running upward); OM = "side adjacent" to O (positive if running to the right); OP = "hypotenuse" or "radius" (may always be taken as positive); and the six ratios between these sides are the principal trigonometric

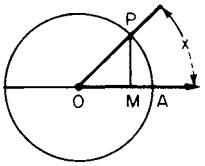

Fig. 2.1.58 Unit circle showing elements used in trigonometric functions.

functions of the angle x; thus:

$$\begin{aligned} \text{sine of } x &= \sin x = \text{opp/hyp} = MP/OP \\ \text{cosine of } x &= \cos x = \text{adj/hyp} = OM/OP \\ \text{tangent of } x &= \tan x = \text{opp/adj} = MP/OM \\ \text{cotangent of } x &= \cot x = \text{adj/opp} = OM/MP \\ \text{secant of } x &= \sec x = \text{hyp/adj} = OP/OM \\ \text{cosecant of } x &= \csc x = \text{hyp/opp} = OP/MP \end{aligned}$$

The last three are best remembered as the reciprocals of the first three:

$$\cot x = 1/\tan x \qquad \sec x = 1/\cos x \qquad \csc x = 1/\sin x$$

Trigonometric functions, the exponential functions, and complex numbers are all related by the **Euler formula:** $e^{ix} = \cos x + i \sin x$, where $i = \sqrt{-1}$. A special case of this $e^{i\pi} = -1$. Note that here x must be measured in radians.

Variations in the functions as x varies from 0 to 360° are shown in Table 2.1.3. The variations in the sine and cosine are best remembered by noting the changes in the lines MP and OM (Fig. 2.1.59) in the "unit circle" (i.e., a circle with radius = OP = 1), as P moves around the circumference.

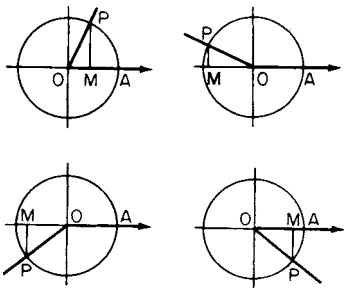

Fig. 2.1.59 Unit circle showing angles in the various quadrants.

Table 2.1.3 Ranges of the Trigonometric Functions

					Values at		
x in DEG	0° to 90°	90° to 180°	180° to 270°	270° to 360°	30°	45°	60°
x in RAD	(0 to $\pi/2$)	($\pi/2$ to π)	(π to $3\pi/2$)	($3\pi/2$ to 2π)	($\pi/6$)	($\pi/4$)	($\pi/3$)
sin x	+0 to +1	+1 to +0	−0 to −1	−1 to −0	1/2	$\frac{1}{2}\sqrt{2}$	$\frac{1}{2}\sqrt{3}$
csc x	+∞ to +1	+1 to +∞	−∞ to −1	−1 to −∞	2	$\sqrt{2}$	$\frac{2}{3}\sqrt{3}$
cos x	+1 to +0	−0 to −1	−1 to −0	+0 to +1	$\frac{1}{2}\sqrt{3}$	$\frac{1}{2}\sqrt{2}$	1/2
sec x	+1 to +∞	−∞ to −1	−1 to −∞	+∞ to +1	$\frac{2}{3}\sqrt{3}$	$\sqrt{2}$	2
tan x	+0 to +∞	−∞ to −0	+0 to +∞	−∞ to −0	$\frac{1}{2}\sqrt{3}$	1	$\sqrt{3}$
cot x	+∞ to +0	−0 to −∞	+∞ to +0	−0 to −∞	$\sqrt{3}$	1	$\frac{1}{3}\sqrt{3}$

To Find Any Function of a Given Angle (Reduction to the first quadrant.) It is often required to find the functions of any angle x from a table that includes only angles between 0 and 90°. If x is not already between 0 and 360°, first "reduce to the first revolution" by simply adding or subtracting the proper multiple of 360° [for any function of (x) = the same function of $(x \pm n \times 360°)$]. Next **reduce to first quadrant** per table below.

If x is between	90° and 180° ($\pi/2$ and π)	180° and 270° (π and $3\pi/2$)	270° and 360° ($3\pi/2$ and 2π)
Subtract	90° from x ($\pi/2$)	180° from x (π)	270° from x ($3\pi/2$)
Then **sin x**	$= +\cos\,(x - 90°)$	$= -\sin\,(x - 180°)$	$= -\cos\,(x - 270°)$
csc x	$= +\sec\,(x - 90°)$	$= -\csc\,(x - 180°)$	$= -\sec\,(x - 270°)$
cos x	$= -\sin\,(x - 90°)$	$= -\cos\,(x - 180°)$	$= +\sin\,(x - 270°)$
sec x	$= -\csc\,(x - 90°)$	$= -\sec\,(x - 180°)$	$= +\csc\,(x - 270°)$
tan x	$= -\cot\,(x - 90°)$	$= +\tan\,(x - 180°)$	$= -\cot\,(x - 270°)$
cot x	$= -\tan\,(x - 90°)$	$= +\cot\,(x - 180°)$	$= -\tan\,(x - 270°)$

The "reduced angle" $(x - 90°$, or $x - 180°$, or $x - 270°)$ will in each case be an angle between 0 and 90°, whose functions can then be found in the table.

NOTE. The formulas for sine and cosine are best remembered by aid of the unit circle.

To Find the Angle When One of Its Functions Is Given In general, there will be two angles between 0 and 360° corresponding to any given function. The rules showing how to find these angles are tabulated below.

Given	First find an *acute* angle x_0 such that	Then the required angles x_1 and x_2 will be*
$\sin x = +a$	$\sin x_0 = a$	x_0 and $180° - x_0$
$\cos x = +a$	$\cos x_0 = a$	x_0 and $[360° - x_0]$
$\tan x = +a$	$\tan x_0 = a$	x_0 and $[180° + x_0]$
$\cot x = +a$	$\cot x_0 = a$	x_0 and $[180° + x_0]$
$\sin x = -a$	$\sin x_0 = a$	$[180° + x_0]$ and $[360° - x_0]$
$\cos x = -a$	$\cos x_0 = a$	$180° - x_0$ and $[180° + x_0]$
$\tan x = -a$	$\tan x_0 = a$	$180° - x_0$ and $[360° - x_0]$
$\cot x = -a$	$\cot x_0 = a$	$180° - x_0$ and $[360° - x_0]$

* The angles enclosed in brackets lie outside the range 0 to 180 deg and hence cannot occur as angles in a triangle.

Relations Among the Functions of a Single Angle

$$\sin^2 x + \cos^2 x = 1$$

$$\tan x = \frac{\sin x}{\cos x}$$

$$\cot x = \frac{1}{\tan x} = \frac{\cos x}{\sin x}$$

$$1 + \tan^2 x = \sec^2 x = \frac{1}{\cos^2 x}$$

$$1 + \cot^2 x = \csc^2 x = \frac{1}{\sin^2 x}$$

$$\sin x = \sqrt{1 - \cos^2 x} = \frac{\tan x}{\sqrt{1 + \tan^2 x}} = \frac{1}{\sqrt{1 + \cot^2 x}}$$

$$\cos x = \sqrt{1 - \sin^2 x} = \frac{1}{\sqrt{1 + \tan^2 x}} = \frac{\cot x}{\sqrt{1 + \cot^2 x}}$$

Functions of Negative Angles $\sin(-x) = -\sin x$; $\cos(-x) = \cos x$; $\tan(-x) = -\tan x$.

Functions of the Sum and Difference of Two Angles

$$\sin(x + y) = \sin x \cos y + \cos x \sin y$$
$$\cos(x + y) = \cos x \cos y - \sin x \sin y$$
$$\tan(x + y) = (\tan x + \tan y)/(1 - \tan x \tan y)$$
$$\cot(x + y) = (\cot x \cot y - 1)/(\cot x + \cot y)$$
$$\sin(x - y) = \sin x \cos y - \cos x \sin y$$
$$\cos(x - y) = \cos x \cos y + \sin x \sin y$$
$$\tan(x - y) = (\tan x - \tan y)/(1 + \tan x \tan y)$$
$$\cot(x - y) = (\cot x \cot y + 1)/(\cot y - \cot x)$$
$$\sin x + \sin y = 2 \sin \tfrac{1}{2}(x + y) \cos \tfrac{1}{2}(x - y)$$
$$\sin x - \sin y = 2 \cos \tfrac{1}{2}(x + y) \sin \tfrac{1}{2}(x - y)$$
$$\cos x + \cos y = 2 \cos \tfrac{1}{2}(x + y) \cos \tfrac{1}{2}(x - y)$$
$$\cos x - \cos y = -2 \sin \tfrac{1}{2}(x + y) \sin \tfrac{1}{2}(x - y)$$

$$\tan x + \tan y = \frac{\sin(x + y)}{\cos x \cos y}; \quad \cot x + \cot y = \frac{\sin(x + y)}{\sin x \sin y}$$

$$\tan x - \tan y = \frac{\sin(x - y)}{\cos x \cos y}; \quad \cot x - \cot y = \frac{\sin(x - y)}{\sin x \sin y}$$

$$\sin^2 x - \sin^2 y = \cos^2 y - \cos^2 x = \sin(x + y) \sin(x - y)$$
$$\cos^2 x - \sin^2 y = \cos^2 y - \sin^2 x = \cos(x + y) \cos(x - y)$$
$$\sin(45° + x) = \cos(45° - x)$$
$$\tan(45° + x) = \cot(45° - x)$$
$$\sin(45° - x) = \cos(45° + x)$$
$$\tan(45° - x) = \cot(45° + x)$$

In the following transformations, a and b are supposed to be positive, $c = \sqrt{a^2 + b^2}$, A = the positive acute angle for which $\tan A = a/b$, and B = the positive acute angle for which $\tan B = b/a$:

$$a \cos x + b \sin x = c \sin(A + x) = c \cos(B - x)$$
$$a \cos x - b \sin x = c \sin(A - x) = c \cos(B + x)$$

Functions of Multiple Angles and Half Angles

$$\sin 2x = 2 \sin x \cos x; \quad \sin x = 2 \sin \tfrac{1}{2}x \cos \tfrac{1}{2}x$$
$$\cos 2x = \cos^2 x - \sin^2 x = 1 - 2 \sin^2 x = 2 \cos^2 x - 1$$

$$\tan 2x = \frac{2 \tan x}{1 - \tan^2 x} \qquad \cot 2x = \frac{\cot^2 x - 1}{2 \cot x}$$

$$\sin 3x = 3 \sin x - 4 \sin^3 x; \quad \tan 3x = \frac{3 \tan x - \tan^3 x}{1 - 3 \tan^2 x}$$

$$\cos 3x = 4 \cos^3 x - 3 \cos x$$

$$\sin(nx) = n \sin x \cos^{n-1} x - (n)_3 \sin^3 x \cos^{n-3} x + (n)_5 \sin^5 x \cos^{n-5} x - \cdots$$

$$\cos(nx) = \cos^n x - (n)_2 \sin^2 x \cos^{n-2} x + (n)_4 \sin^4 x \cos^{n-4} x - \cdots$$

where $(n)_2$, $(n)_3$, . . . , are the binomial coefficients.

$$\sin \tfrac{1}{2}x = \pm\sqrt{\tfrac{1}{2}(1 - \cos x)}. \quad 1 - \cos x = 2 \sin^2 \tfrac{1}{2} x$$

$$\cos \tfrac{1}{2}x = \pm\sqrt{\tfrac{1}{2}(1 + \cos x)}. \quad 1 + \cos x = 2 \cos^2 \tfrac{1}{2} x$$

$$\tan \tfrac{1}{2}x = \pm\sqrt{\frac{1 - \cos x}{1 + \cos x}} = \frac{\sin x}{1 + \cos x} = \frac{1 - \cos x}{\sin x}$$

$$\tan\left(\frac{x}{2} + 45°\right) = \pm\sqrt{\frac{1 + \sin x}{1 - \sin x}}$$

Here the + or − sign is to be used according to the sign of the left-hand side of the equation.

Approximations for sin *x*, cos *x*, and tan *x* For small values of x, x measured in radians, the following approximations hold:

$$\sin x \approx x \qquad \tan x \approx x \qquad \cos x \approx 1 - \frac{x^2}{2}$$

The following actually hold:

$$\sin x < x < \tan x \qquad \cos x < \frac{\sin x}{x} < 1$$

As x approaches 0, $\lim [(\sin x)/x] = 1$.

Inverse Trigonometric Functions The notation $\sin^{-1} x$ (read: arcsine of x, or inverse sine of x) means the principal angle whose sine is x. Similarly for $\cos^{-1} x$, $\tan^{-1} x$, etc. (The principal angle means an angle between -90 and $+90°$ in case of $\sin^{-1}$ and $\tan^{-1}$, and between 0 and 180° in the case of $\cos^{-1}$.)

Solution of Plane Triangles

The "parts" of a plane triangle are its three sides a, b, c, and its three angles A, B, C (A being opposite a). Two triangles are **congruent** if all their corresponding parts are equal. Two triangles are **similar** if their corresponding angles are equal, that is, $A_1 = A_2$, $B_1 = B_2$, and $C_1 = C_2$. Similar triangles may differ in scale, but they satisfy $a_1/a_2 = b_1/b_2 = c_1/c_2$.

Two different triangles may have two corresponding sides and the angle opposite one of those sides equal (Fig. 2.1.60), and still not be congruent. This is the **angle-side-side theorem.**

Otherwise, a triangle is uniquely determined by any three of its parts, as long as those parts are not all angles. To "solve" a triangle means to find the unknown parts from the known. The fundamental formulas are

$$\text{Law of sines: } \frac{a}{b} = \frac{\sin A}{\sin B}$$

$$\text{Law of cosines: } c^2 = a^2 + b^2 - 2ab \cos C$$

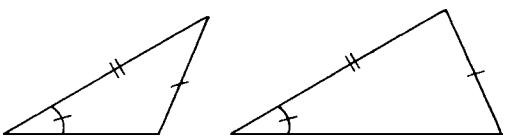

Fig. 2.1.60 Triangles with an angle, an adjacent side, and an opposite side given.

Right Triangles Use the definitions of the trigonometric functions, selecting for each unknown part a relation which connects that unknown with known quantities; then solve the resulting equations. Thus, in Fig. 2.1.61, if $C = 90°$, then $A + B = 90°$, $c^2 = a^2 + b^2$,

$$\sin A = a/c \qquad \cos A = b/c$$
$$\tan A = a/b \qquad \cot A = b/a$$

If A is very small, use $\tan \frac{1}{2} A = \sqrt{c - b)/(c + b)}$.

Oblique Triangles There are four cases. It is highly desirable in all these cases to draw a sketch of the triangle approximately to scale before commencing the computation, so that any large numerical error may be readily detected.

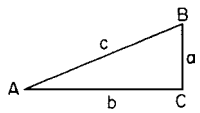

Fig. 2.1.61 Right triangle.

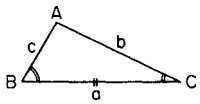

Fig. 2.1.62 Triangle with two angles and the included side given.

CASE 1. GIVEN TWO ANGLES (provided their sum is $< 180°$) AND ONE SIDE (say a, Fig. 2.1.62). The third angle is known since $A + B + C = 180°$. To find the remaining sides, use

$$b = \frac{a \sin B}{\sin A} \qquad c = \frac{a \sin C}{\sin A}$$

Or, drop a perpendicular from either B or C on the opposite side, and solve by right triangles.

Check: $c \cos B + b \cos C = a$.

CASE 2. GIVEN TWO SIDES (say a and b) AND THE INCLUDED ANGLE (C); AND SUPPOSE $a > b$ (Fig. 2.1.63).

Method 1: Find c from $c^2 = a^2 + b^2 - 2ab \cos C$; then find the smaller angle, B, from $\sin B = (b/c) \sin C$; and finally, find A from $A = 180° - (B + C)$.

Check: $a \cos B + b \cos A = c$.

Method 2: Find $\frac{1}{2}(A - B)$ from the law of tangents:

$$\tan \tfrac{1}{2}(A - B) = [(a - b)/(a + b)] \cot \tfrac{1}{2}C$$

and $\frac{1}{2}(A + B)$ from $\frac{1}{2}(A + B) = 90° - C/2$; hence $A = \frac{1}{2}(A + B) + \frac{1}{2}(A - B)$ and $B = \frac{1}{2}(A + B) - \frac{1}{2}(A - B)$. Then find c from $c = a \sin C/\sin A$ or $c = b \sin C/\sin B$.

Check: $a \cos B + b \cos A = c$.

Method 3: Drop a perpendicular from A to the opposite side, and solve by right triangles.

CASE 3. GIVEN THE THREE SIDES (provided the largest is less than the sum of the other two) (Fig. 2.1.64).

Method 1: Find the largest angle A (which may be acute or obtuse) from $\cos A = (b^2 + c^2 - a^2)/2bc$ and then find B and C (which will always be acute) from $\sin B = b \sin A/a$ and $\sin C = c \sin A/a$.

Check: $A + B + C = 180°$.

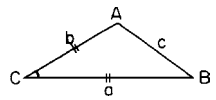

Fig. 2.1.63 Triangle with two sides and the included angle given.

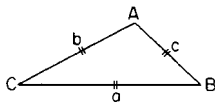

Fig. 2.1.64 Triangle with three sides given.

Method 2: Find A, B, and C from $\tan \frac{1}{2}A = r/(s - a)$, $\tan \frac{1}{2}B = r/(s - b)$, $\tan \frac{1}{2}C = r/(s - c)$, where $s = \frac{1}{2}(a + b + c)$, and $r = \sqrt{(s - a)(s - b)(s - c)/s}$. *Check:* $A + B + C = 180°$.

Method 3: If only one angle, say A, is required, use

$$\sin \tfrac{1}{2}A = \sqrt{(s - b)(s - c)/bc}$$

or

$$\cos \tfrac{1}{2}A = \sqrt{s(s - a)/bc}$$

according as $\frac{1}{2}A$ is nearer 0° or nearer 90°.

CASE 4. GIVEN TWO SIDES (say b and c) AND THE ANGLE OPPOSITE ONE OF THEM (B). This is the "ambiguous case" in which there may be two solutions, or one, or none.

First, try to find $C = c \sin B/b$. If $\sin C > 1$, there is no solution. If $\sin C = 1$, $C = 90°$ and the triangle is a right triangle. If $\sin C < 1$, this determines two angles C, namely, an acute angle C_1, and an obtuse angle $C_2 = 180° - C_1$. Then C_1 will yield a solution when and only when $C_1 + B < 180°$ (see Case 1); and similarly C_2 will yield a solution when and only when $C_2 + B < 180°$ (see Case 1).

Other Properties of Triangles (See also Geometry, Areas, and Volumes.)

Area $= \frac{1}{2}ab \sin C = \sqrt{s(s - a)(s - b)(s - c)} = rs$ where $s = \frac{1}{2}(a + b + c)$, and r = radius of inscribed circle $= \sqrt{(s - a)(s - b)(s - c)/s}$.

Radius of circumscribed circle $= R$, where

$$2R = a/\sin A = b/\sin B = c/\sin C$$

$$r = 4R \sin\frac{A}{2} \sin\frac{B}{2} \sin\frac{C}{2} = \frac{abc}{4Rs}$$

The length of the bisector of the angle C is

$$z = \frac{2\sqrt{abs(s-c)}}{a+b} = \frac{\sqrt{ab[(a+b)^2 - c^2]}}{a+b}$$

The median from C to the middle point of c is $m = \frac{1}{2}\sqrt{2(a^2+b^2) - c^2}$.

Hyperbolic Functions

The **hyperbolic sine, hyperbolic cosine,** etc., of any number x, are functions of x which are closely related to the exponential e^x, and which have formal properties very similar to those of the trigonometric functions, sine, cosine, etc. Their definitions and fundamental properties are as follows:

$$\sinh x = \tfrac{1}{2}(e^x - e^{-x})$$
$$\cosh x = \tfrac{1}{2}(e^x + e^{-x})$$
$$\tanh x = \sinh x/\cosh x$$

$$\cosh x + \sinh x = e^x$$
$$\cosh x - \sinh x = e^{-x}$$

$$\operatorname{csch} x = 1/\sinh x$$
$$\operatorname{sech} x = 1/\cosh x$$
$$\coth x = 1/\tanh x$$

$$\cosh^2 x - \sinh^2 x = 1$$
$$1 - \tanh^2 x = \operatorname{sech}^2 x$$
$$1 - \coth^2 x = -\operatorname{csch}^2 x$$

$$\sinh(-x) = -\sinh x$$
$$\cosh(-x) = \cosh x$$
$$\tanh(-x) = -\tanh x$$

$$\sinh(x \pm y) = \sinh x \cosh y \pm \cosh x \sinh y$$
$$\cosh(x \pm y) = \cosh x \cosh y \pm \sinh x \sinh y$$
$$\tanh(x \pm y) = (\tanh x \pm \tanh y)/(1 \pm \tanh x \tanh y)$$

$$\sinh 2x = 2 \sinh x \cosh x$$
$$\cosh 2x = \cosh^2 x + \sinh^2 x$$
$$\tanh 2x = (2 \tanh x)/(1 + \tanh^2 x)$$

$$\sinh \tfrac{1}{2}x = \sqrt{\tfrac{1}{2}(\cosh x - 1)}$$
$$\cosh \tfrac{1}{2}x = \sqrt{\tfrac{1}{2}(\cosh x + 1)}$$
$$\tanh \tfrac{1}{2}x = (\cosh x - 1)/(\sinh x) = (\sinh x)/(\cosh x + 1)$$

The hyperbolic functions are related to the rectangular hyperbola, $x^2 - y^2 = a^2$ (Fig. 2.1.66), in much the same way that the trigonometric functions are related to the circle $x^2 + y^2 = a^2$ (Fig. 2.1.65); the analogy, however, concerns not angles but areas. Thus, in either figure, let A

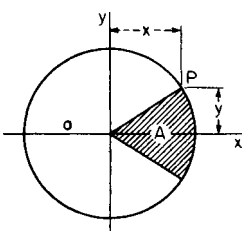

Fig. 2.1.65 Circle.

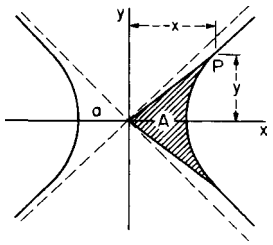

Fig. 2.1.66 Hyperbola.

represent the shaded area, and let $u = A/a^2$ (a pure number). Then for the coordinates of the point P we have, in Fig. 2.1.65, $x = a \cos u$, $y = a \sin u$; and in Fig. 2.1.66, $x = a \cosh u$, $y = a \sinh u$.

The **inverse hyperbolic sine** of y, denoted by $\sinh^{-1} y$, is the number whose hyperbolic sine is y; that is, the notation $x = \sinh^{-1} y$ means $\sinh x = y$. Similarly for $\cosh^{-1} y$, $\tanh^{-1} y$, etc. These functions are closely related to the logarithmic function, and are especially valuable in the integral calculus.

$$\sinh^{-1}(y/a) = \ln(y + \sqrt{y^2 + a^2}) - \ln a$$
$$\cosh^{-1}(y/a) = \ln(y + \sqrt{y^2 - a^2}) - \ln a$$
$$\tanh^{-1}\frac{y}{a} = \tfrac{1}{2}\ln\frac{a+y}{a-y}$$
$$\coth^{-1}\frac{y}{a} = \tfrac{1}{2}\ln\frac{y+a}{y-a}$$

ANALYTICAL GEOMETRY

The Point and the Straight Line

Rectangular Coordinates (Fig. 2.1.67) Let $P_1 = (x_1, y_1)$, $P_2 = (x_2, y_2)$. Then, distance

$$P_1P_2 = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

slope of $P_1P_2 = m = \tan u = (y_2 - y_1)/(x_2 - x_1)$; coordinates of midpoint are $x = \frac{1}{2}(x_1 + x_2)$, $y = \frac{1}{2}(y_1 + y_2)$; coordinates of point $1/n$th of the way from P_1 to P_2 are $x = x_1 + (1/n)(x_2 - x_1)$, $y = y_1 + (1/n)(y_2 - y_1)$.

Let m_1, m_2 be the slopes of two lines; then, if the lines are parallel, $m_1 = m_2$; if the lines are perpendicular to each other, $m_1 = -1/m_2$.

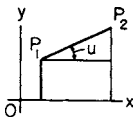

Fig. 2.1.67 Graph of straight line.

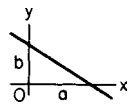

Fig. 2.1.68 Graph of straight line showing intercepts.

Equations of a Straight Line

1. *Intercept form* (Fig. 2.1.68). $x/a + y/b = 1$. (a, b = intercepts of the line on the axes.)
2. *Slope form* (Fig. 2.1.69). $y = mx + b$. ($m = \tan u$ = slope; b = intercept on the y axis.)
3. *Normal form* (Fig. 2.1.70). $x \cos v + y \sin v = p$. (p = perpendicular from origin to line; v = angle from the x axis to p.)

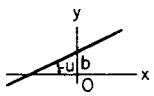

Fig. 2.1.69 Graph of straight line showing slope and vertical intercept.

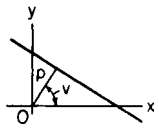

Fig. 2.1.70 Graph of straight line showing perpendicular line from origin.

4. *Parallel-intercept form* (Fig. 2.1.71). $\dfrac{y-b}{c-b} = \dfrac{x}{k}$ ($b = y$ intercept, c = intercept on the parallel $x = k$).

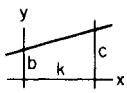

Fig. 2.1.71 Graph of straight line showing intercepts on parallel lines.

5. *General form.* $Ax + By + C = 0$. [Here $a = -C/A$, $b = -C/B$, $m = -A/B$, $\cos v = A/R$, $\sin v = B/R$, $p = -C/R$, where $R = \pm\sqrt{A^2 + B^2}$ (sign to be so chosen that p is positive).]
6. *Line through* (x_1, y_1) *with slope* m. $y - y_1 = m(x - x_1)$.

7. *Line through* (x_1, y_1) *and* (x_2, y_2). $y - y_1 = \dfrac{y_2 - y_1}{x_2 - x_1}(x - x_1)$.

8. *Line parallel to x axis.* $y = a$; to y axis: $x = b$.

Angles and Distances If u = angle from the line with slope m_1 to the line with slope m_2, then

$$\tan u = \frac{m_2 - m_1}{1 + m_2 m_1}$$

If parallel, $m_1 = m_2$.
If perpendicular, $m_1 m_2 = -1$.

If u = angle between the lines $Ax + By + C = 0$ and $A'x + B'y + C' = 0$, then

$$\cos u = \frac{AA' + BB'}{\pm\sqrt{(A^2 + B^2)(A'^2 + B'^2)}}$$

If parallel, $A/A' = B/B'$.
If perpendicular, $AA' + BB' = 0$.

The equation of a line through (x_1, y_1) and meeting a given line $y = mx + b$ at an angle u, is

$$y - y_1 = \frac{m + \tan u}{1 - m \tan u}(x - x_1)$$

The distance from (x_0, y_0) to the line $Ax + By + C = 0$ is

$$D = \left| \frac{Ax_0 + By_0 + C}{\sqrt{A^2 + B^2}} \right|$$

where the vertical bars mean "the absolute value of."

The distance from (x_0, y_0) to a line which passes through (x_1, y_1) and makes an angle u with the x axis is

$$D = (x_0 - x_1) \sin u - (y_0 - y_1) \cos u$$

Polar Coordinates (Fig. 2.1.72) Let (x, y) be the rectangular and (r, θ) the polar coordinates of a given point P. Then $x = r \cos \theta$; $y = r \sin \theta$; $x^2 + y^2 = r^2$.

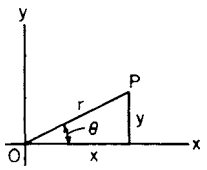

Fig. 2.1.72 Polar coordinates.

Transformation of Coordinates If origin is moved to point (x_0, y_0), the new axes being parallel to the old, $x = x_0 + x'$, $y = y_0 + y'$.

If axes are turned through the angle u, without change of origin,

$$x = x' \cos u - y' \sin u \qquad y = x' \sin u + y' \cos u$$

The Circle

The **equation of a circle** with center (a, b) and radius r is

$$(x - a)^2 + (y - b)^2 = r^2$$

If center is at the origin, the equation becomes $x^2 + y^2 = r^2$. If circle goes through the origin and center is on the x axis at point $(r, 0)$, equation becomes $x^2 + y^2 = 2rx$. The **general equation** of a circle is

$$x^2 + y^2 + Dx + Ey + F = 0$$

It has center at $(-D/2, -E/2)$, and radius $= \sqrt{(D/2)^2 + (E/2)^2 - F}$ (which may be real, null, or imaginary).

Equations of Circle in Parametric Form It is sometimes convenient to express the coordinates x and y of the moving point P (Fig. 2.1.73) in terms of an auxiliary variable, called a **parameter.** Thus, if the parameter be taken as the angle u from the x axis to the radius vector OP, then the equations of the circle in parametric form will be $x = a \cos u$; $y = a \sin u$. For every value of the parameter u, there corresponds a point (x, y) on the circle. The ordinary equation $x^2 + y^2 = a^2$ can be obtained from the parametric equations by eliminating u. The equation of a circle with radius a and center at (h, k) in parametric form will be $x = h + a \cos u$; $y = k + a \sin u$.

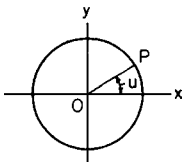

Fig. 2.1.73 Parameters of a circle.

The Parabola

The **parabola** is the locus of a point which moves so that its distance from a fixed line (called the **directrix**) is always equal to its distance from a fixed point F (called the **focus**). See Fig. 2.1.74. The point halfway from focus to directrix is the **vertex,** O. The line through the focus, perpendicular to the directrix, is the **principal axis.** The breadth of the curve at the focus is called the **latus rectum,** or **parameter,** $= 2p$, where p is the distance from focus to directrix.

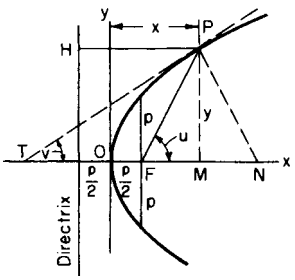

Fig. 2.1.74 Graph of parabola.

NOTE. Any section of a right circular cone made by a plane parallel to a tangent plane of the cone will be a parabola.

Equation of parabola, principal axis along the x axis, origin at vertex (Fig. 2.1.74): $y^2 = 2px$.

Polar equation of parabola, referred to F as origin and Fx as axis (Fig. 2.1.75): $r = p/(1 - \cos \theta)$.

Equation of parabola with principal axis parallel to y axis: $y = ax^2 + bx + c$. This may be rewritten, using a technique called **completing the square:**

$$y = a\left[x^2 + \frac{b}{a}x + \frac{b^2}{4a^2}\right] + c - \frac{b^2}{4a}$$

$$= a\left[x + \frac{b}{2a}\right]^2 + c - \frac{b^2}{4a}$$

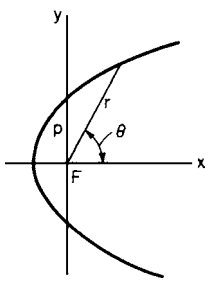

Fig. 2.1.75 Polar plot of parabola.

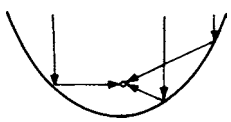

Fig. 2.1.76 Vertical parabola showing rays passing through the focus.

Then: vertex is the point $[-b/2a, c - b^2/4a]$; latus rectum is $p = 1/2a$; and focus is the point $[-b/2a, c - b^2/4a + 1/4a]$.

A parabola has the special property that lines parallel to its principal axis, when reflected off the inside "surface" of the parabola, will all pass through the focus (Fig. 2.1.76). This property makes parabolas useful in designing mirrors and antennas.

The Ellipse

The **ellipse** (as shown in Fig. 2.1.77), has two **foci,** F and F', and two **directrices,** DH and $D'H'$. If P is any point on the curve, $PF + PF'$ is constant, $= 2a$; and PF/PH (or PF'/PH') is also constant, $= e$, where e is the **eccentricity** ($e < 1$). Either of these properties may be taken as the definition of the curve. The relations between e and the semiaxes a and b are as shown in Fig. 2.1.78. Thus, $b^2 = a^2(1 - e^2)$, $ae = \sqrt{a^2 - b^2}$, $e^2 = 1 - (b/a)^2$. The **semilatus rectum** $= p = a(1 - e^2) = b^2/a$. Note that b is always less than a, except in the special case of the circle, in which $b = a$ and $e = 0$.

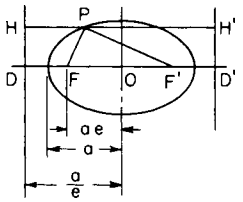

Fig. 2.1.77 Ellipse.

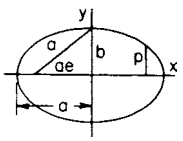

Fig. 2.1.78 Ellipse showing semiaxes.

Any section of a right circular cone made by a plane which cuts all the elements of one nappe of the cone will be an ellipse; if the plane is perpendicular to the axis of the cone, the ellipse becomes a circle.

Equation of ellipse, center at origin:

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \qquad \text{or} \qquad y = \pm \frac{b}{a}\sqrt{a^2 - x^2}$$

If $P = (x, y)$ is any point of the curve, $PF = a + ex$, $PF' = a - ex$.

Equations of the ellipse in parametric form: $x = a \cos u$, $y = b \sin u$, where u is the eccentric angle of the point $P = (x, y)$. See Fig. 2.1.81.

Polar equation, focus as origin, axes as in Fig. 2.1.79. $r = p/(1 - e \cos \theta)$.

Equation of the tangent at (x_1, y_1): $b^2x_1x + a^2y_1y = a^2b^2$.

The line $y = mx + k$ will be a tangent if $k = \pm\sqrt{a^2m^2 + b^2}$.

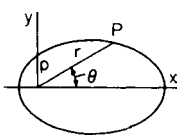

Fig. 2.1.79 Ellipse in polar form.

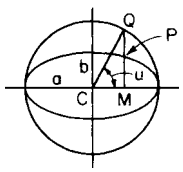

Fig. 2.1.80 Ellipse as a flattened circle.

Ellipse as a Flattened Circle, Eccentric Angle If the ordinates in a circle are diminished in a constant ratio, the resulting points will lie on an ellipse (Fig. 2.1.80). If Q traces the circle with uniform velocity, the corresponding point P will trace the ellipse, with varying velocity. The angle u in the figure is called the eccentric angle of the point P.

A consequence of this property is that if a circle is drawn with its horizontal scale different from its vertical scale, it will appear to be an ellipse. This phenomenon is common in computer graphics.

The **radius of curvature of an ellipse at any point** $P = (x, y)$ is

$$R = a^2b^2(x^2/a^4 + y^2/b^4)^{3/2} = p/\sin^3 v$$

where v is the angle which the tangent at P makes with PF or PF'. At end of major axis, $R = b^2/a = MA$; at end of minor axis, $R = a^2/b = NB$ (see Fig. 2.1.81).

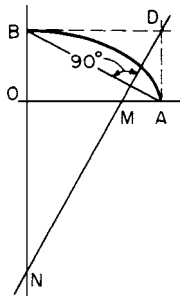

Fig. 2.1.81 Ellipse showing radius of curvature.

The Hyperbola

The **hyperbola** has two **foci,** F and F', at distances $\pm ae$ from the center, and two **directrices,** DH and $D'H'$, at distances $\pm a/e$ from the center (Fig. 2.1.82). If P is any point of the curve, $|PF - PF'|$ is constant, $= 2a$; and PF/PH (or PF'/PH') is also constant, $= e$ (called the **eccentricity**), where $e > 1$. Either of these properties may be taken as the

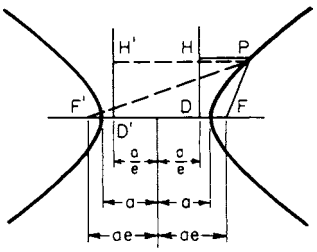

Fig. 2.1.82 Hyperbola.

definition of the curve. The curve has two branches which approach more and more nearly two straight lines called the **asymptotes.** Each asymptote makes with the principal axis an angle whose tangent is b/a. The relations between e, a, and b are shown in Fig. 2.1.83: $b^2 = a^2(e^2 - 1)$, $ae = \sqrt{a^2 + b^2}$, $e^2 = 1 + (b/a)^2$. The semilatus rectum, or ordinate at the focus, is $p = a(e^2 - 1) = b^2/a$.

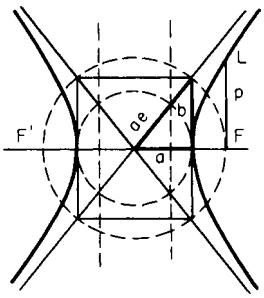

Fig. 2.1.83 Hyperbola showing the asymptotes.

Any section of a right circular cone made by a plane which cuts both nappes of the cone will be a hyperbola.

Equation of the hyperbola, center as origin:

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1 \qquad \text{or} \qquad y = \pm \frac{b}{a}\sqrt{x^2 - a^2}$$

If $P = (x, y)$ is on the right-hand branch, $PF = ex - a$, $PF' = ex + a$. If P is on the left-hand branch, $PF = -ex + a$, $PF' = -ex - a$.

Equations of Hyperbola in Parametric Form (1) $x = a \cosh u$, $y = b \sinh u$. Here u may be interpreted as A/ab, where A is the area shaded in Fig. 2.1.84. (2) $x = a \sec v$, $y = b \tan v$, where v is an auxiliary angle of no special geometric interest.

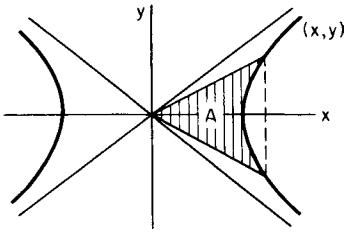

Fig. 2.1.84 Hyperbola showing parametric form.

Polar equation, referred to focus as origin, axes as in Fig. 2.1.85:

$$r = p/(1 - e \cos \theta)$$

Equation of tangent at (x_1, y_1): $b^2x_1x - a^2y_1y = a^2b^2$. The line $y = mx + k$ will be a tangent if $k = \pm\sqrt{a^2m^2 - b^2}$.

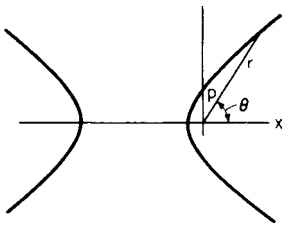

Fig. 2.1.85 Hyperbola in polar form.

The triangle bounded by the asymptotes and a variable tangent is of constant area, $= ab$.

Conjugate hyperbolas are two hyperbolas having the same asymptotes with semiaxes interchanged (Fig. 2.1.86). The equations of the hyperbola conjugate to $x^2/a^2 - y^2/b^2 = 1$ is $x^2/a^2 - y^2/b^2 = -1$.

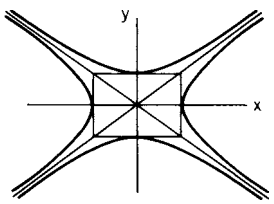

Fig. 2.1.86 Conjugate hyperbolas.

Equilateral Hyperbola ($a = b$) Equation referred to principal axes (Fig. 2.1.87): $x^2 - y^2 = a^2$.

NOTE. $p = a$ (Fig. 2.1.87). Equation referred to asymptotes as axes (Fig. 2.1.88): $xy = a^2/2$.

Asymptotes are perpendicular. Eccentricity $= \sqrt{2}$. Any diameter is equal in length to its conjugate diameter.

The Catenary

The **catenary** is the curve in which a flexible chain or cord of uniform density will hang when supported by the two ends. Let w = weight of the chain per unit length; T = the tension at any point P; and T_h, T_v = the horizontal and vertical components of T. The horizontal component T_h is the same at all points of the curve.

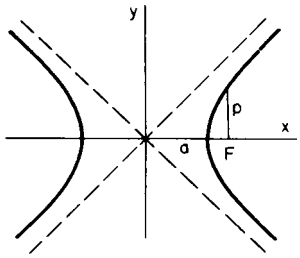

Fig. 2.1.87 Equilateral hyperbola.

The length $a = T_h/w$ is called the **parameter** of the catenary, or the distance from the lowest point O to the **directrix** DQ (Fig. 2.1.89). When a is very large, the curve is very flat.

The rectangular **equation,** referred to the lowest point as origin, is $y = a[\cosh(x/a) - 1]$. In case of very flat arcs (a large), $y = x^2/2a + \cdots$; $s = x + \frac{1}{6}x^3/a^2 + \cdots$, approx, so that in such a case the catenary closely resembles a parabola.

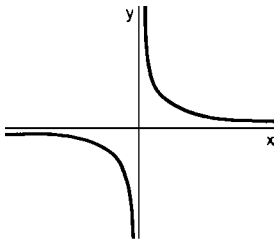

Fig. 2.1.88 Hyperbola with asymptotes as axes.

Calculus properties of the catenary are often discussed in texts on the calculus of variations (Weinstock, "Calculus of Variations," Dover; Ewing, "Calculus of Variations with Applications," Dover).

Problems on the Catenary (Fig. 2.1.89) When any two of the four quantities, x, y, s, T/w are known, the remaining two, and also the parameter a, can be found, using the following:

$$a = x/z \qquad s = a \sinh z$$
$$T = wa \cosh z \qquad y/x = (\cosh z - 1)/z$$
$$s/x = (\sinh z)/z \qquad wx/T = z \cosh z$$

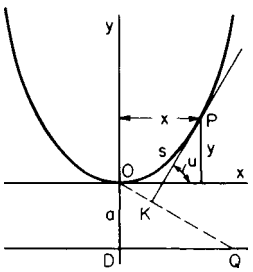

Fig. 2.1.89 Catenary.

NOTE. If $wx/T < 0.6627$, then there are two values of z, one less than 1.2, and one greater. If $wx/T > 0.6627$, then the problem has no solution.

Given the Length $2L$ of a Chain Supported at Two Points A and B Not in the Same Level, to Find a (See Fig. 2.1.90; b and c are supposed known.) Let $(\sqrt{L^2 - b^2})/c = s/x$; use $s/x = \sinh z/z$ to find z. Then $a = c/z$.

NOTE. The coordinates of the midpoint M of AB (see Fig. 2.1.90) are $x_0 = a \tanh^{-1}(b/L)$, $y_0 = (L/\tanh z) - a$, so that the position of the lowest point is determined.

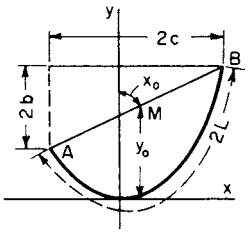

Fig. 2.1.90 Catenary with ends at unequal levels.

Other Useful Curves

The **cycloid** is traced by a point on the circumference of a circle which rolls without slipping along a straight line. Equations of cycloid, in parametric form (axes as in Fig. 2.1.91): $x = a(\text{rad } u - \sin u)$, $y = a(1 - \cos u)$, where a is the radius of the rolling circle, and rad u is the radian measure of the angle u through which it has rolled. The **radius of curvature** at any point P is $PC = 4a \sin (u/2) = 2\sqrt{2ay}$.

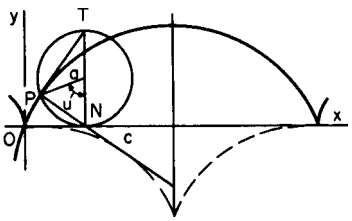

Fig. 2.1.91 Cycloid.

The **trochoid** is a more general curve, traced by any point on a radius of the rolling circle, at distance b from the center (Fig. 2.1.92). It is a prolate trochoid if $b < a$, and a curtate or looped trochoid if $b > a$. The equations in either case are $x = a \text{ rad } u - b \sin u$, $y = a - b \cos u$.

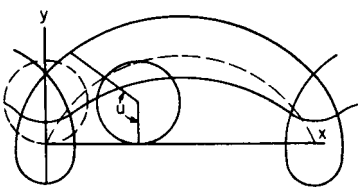

Fig. 2.1.92 Trochoid.

The **epicycloid** (or **hypocycloid)** is a curve generated by a point on the circumference of a circle of radius a which rolls without slipping on the outside (or inside) of a fixed circle of radius c (Fig. 2.1.93 and Fig. 2.1.94). For the **equations,** put $b = a$ in the equations of the epior hypotrochoid, below.

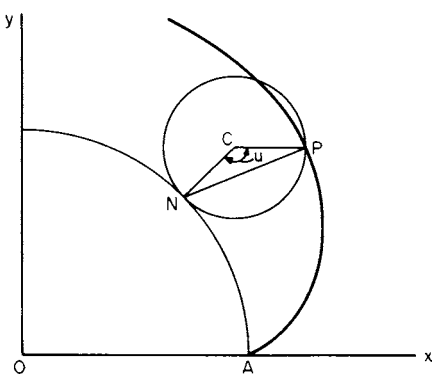

Fig. 2.1.93 Epicycloid.

Radius of curvature at any point P is

$$R = \frac{4a(c \pm a)}{c \pm 2a} \times \sin \tfrac{1}{2}u$$

At A, $R = 0$; at D, $R = \dfrac{4a(c \pm a)}{c \pm 2a}$.

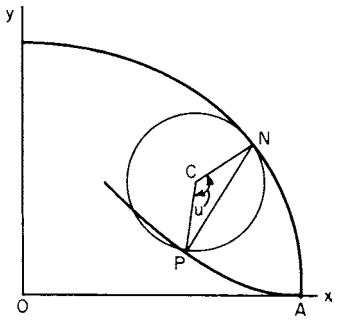

Fig. 2.1.94 Hypocycloid.

Special Cases If $a = \frac{1}{2}c$, the hypocycloid becomes a straight line, diameter of the fixed circle (Fig. 2.1.95). In this case the hypotrochoid traced by any point rigidly connected with the rolling circle (not necessarily on the circumference) will be an ellipse. If $a = \frac{1}{4}c$, the curve generated will be the four-cusped hypocycloid, or **astroid** (Fig. 2.1.96), whose equation is $x^{2/3} + y^{2/3} = c^{2/3}$. If $a = c$, the epicycloid is the **cardioid,** whose equation in polar coordinates (axes as in Fig. 2.1.97) is $r = 2c(1 + \cos \theta)$. Length of cardioid $= 16c$.

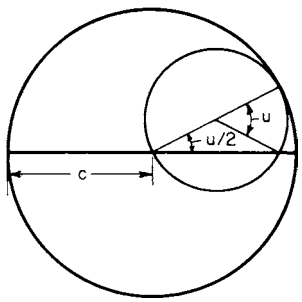

Fig. 2.1.95 Hypocycloid is straight line when the radius of inside circle is half that of the outside circle.

The **epitrochoid** (or **hypotrochoid)** is a curve traced by any point rigidly attached to a circle of radius a, at distance b from the center, when this

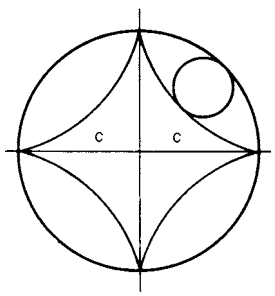

Fig. 2.1.96 Astroid.

circle rolls without slipping on the outside (or inside) of a fixed circle of radius c. The equations are

$$x = (c \pm a)\cos\left(\frac{a}{c}u\right) \pm b\cos\left[\left(1 \pm \frac{a}{c}\right)u\right]$$

$$y = (c \pm a)\sin\left(\frac{a}{c}u\right) - b\sin\left[\left(1 \pm \frac{a}{c}\right)u\right]$$

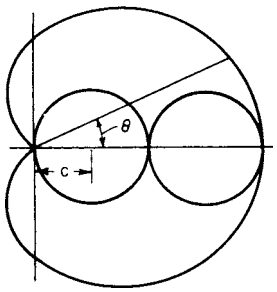

Fig. 2.1.97 Cardioid.

where u = the angle which the moving radius makes with the line of centers; take the upper sign for the epi- and the lower for the hypotrochoid. The curve is called prolate or curtate according as $b < a$ or $b > a$. When $b = a$, the special case of the epi- or hypocycloid arises.

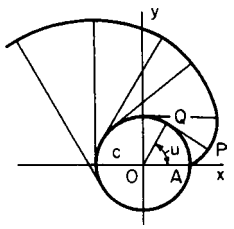

Fig. 2.1.98 Involute of circle.

The **involute of a circle** is the curve traced by the end of a taut string which is unwound from the circumference of a fixed circle, of radius c. If QP is the free portion of the string at any instant (Fig. 2.1.98), QP will be tangent to the circle at Q, and the length of QP = length of arc QA; hence the construction of the curve. The equations of the curve in parametric form (axes as in figure) are $x = c(\cos u + \text{rad } u \sin u)$, $y = c(\sin u - \text{rad } u \cos u)$, where rad u is the radian measure of the angle u which OQ makes with the x axis. Length of arc $AP = \frac{1}{2}c(\text{rad } u)^2$; radius of curvature at P is QP. Polar equations, in terms of parameter

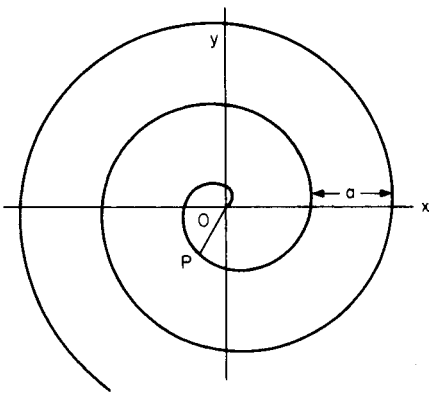

Fig. 2.1.99 Spiral of Archimedes.

v(= angle POQ), are $r = c \sec v$, rad $\theta = \tan v - \text{rad } v$. Here, $r = OP$, and rad θ = radian measure of angle, AOP (Fig. 2.1.98).

The **spiral of Archimedes** (Fig. 2.1.99) is traced by a point P which, starting from O, moves with uniform velocity along a ray OP, while the ray itself revolves with uniform angular velocity about O. Polar equation: $r = k$ rad θ, or $r = a(\theta°/360°)$. Here $a = 2\pi k$ = the distance measured along a radius, from each coil to the next.

The radius of curvature at P is $R = (k^2 + r^2)^{3/2}/(2k^2 + r^2)$.

The **logarithmic spiral** (Fig. 2.1.100) is a curve which cuts the radii from O at a constant angle v, whose cotangent is m. Polar equation: $r = ae^{m\,\text{rad}\,\theta}$. Here a is the value of r when $\theta = 0$. For large negative values of θ, the curve winds around O as an asymptotic point. If PT and PN are the tangent and normal at P, the line TON being perpendicular to OP (not shown in figure), then $ON = rm$, and $PN = r\sqrt{1 + m^2} = r/\sin v$. Radius of curvature at P is PN.

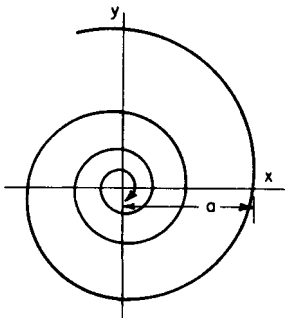

Fig. 2.1.100 Logarithmic spiral.

The **tractrix,** or Schiele's antifriction curve (Fig. 2.1.101), is a curve such that the portion PT of the tangent between the point of contact and the x axis is constant = a. Its equation is

$$x = \pm a\left[\cosh^{-1}\frac{a}{y} - \sqrt{1 - \left(\frac{y}{a}\right)^2}\right]$$

or, in parametric form, $x = \pm a(t - \tanh t)$, $y = a/\cosh t$. The x axis is an asymptote of the curve. Length of arc $BP = a \log_e (a/y)$.

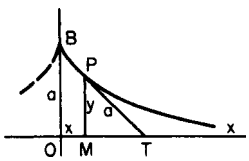

Fig. 2.1.101 Tractrix.

The tractrix describes the path taken by an object being pulled by a string moving along the x axis, where the initial position of the object is B and the opposite end of the string begins at O.

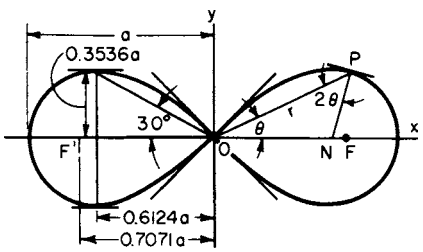

Fig. 2.1.102 Lemniscate.

The **lemniscate** (Fig. 2.1.102) is the locus of a point P the product of whose distances from two fixed points F, F' is constant, equal to $\frac{1}{2}a^2$. The distance $FF' = a\sqrt{2}$. Polar equation is $r = a\sqrt{\cos 2\theta}$. Angle between OP and the normal at P is 2θ. The two branches of the curve cross at right angles at O. Maximum y occurs when $\theta = 30°$ and $r = a/\sqrt{2}$, and is equal to $\frac{1}{4}a\sqrt{2}$. Area of one loop $= a^2/2$.

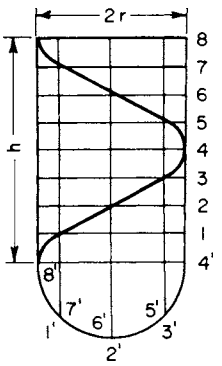

Fig. 2.1.103 Helix.

The helix (Fig. 2.1.103) is the curve of a screw thread on a cylinder of radius r. The curve crosses the elements of the cylinder at a constant angle, v. The pitch, h, is the distance between two coils of the helix, measured along an element of the cylinder; hence $h = 2\pi r \tan v$. Length of one coil $= \sqrt{(2\pi r)^2 + h^2} = 2\pi r/\cos v$. If the cylinder is rolled out on a plane, the development of the helix will be a straight line, with slope equal to $\tan v$.

DIFFERENTIAL AND INTEGRAL CALCULUS

Derivatives and Differentials

Derivatives and Differentials A **function** of a single variable x may be denoted by $f(x)$, $F(x)$, etc. The value of the function when x has the value x_0 is then denoted by $f(x_0)$, $F(x_0)$, etc. The **derivative** of a function $y = f(x)$ may be denoted by $f'(x)$, or by dy/dx. The value of the derivative at a given point $x = x_0$ is the **rate of change** of the function at that point; or, if the function is represented by a curve in the usual way (Fig. 2.1.104), the value of the derivative at any point shows the **slope of the curve** (i.e., the slope of the tangent to the curve) at that point (positive if the tangent points upward, and negative if it points downward, moving to the right).

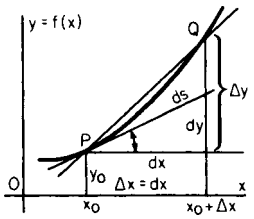

Fig. 2.1.104 Curve showing tangent and derivatives.

The **increment** Δy (read: "delta y") in y is the change produced in y by increasing x from x_0 to $x_0 + \Delta x$; i.e., $\Delta y = f(x_0 + \Delta x) - f(x_0)$. The **differential,** dy, of y is the value which Δy would have if the curve coincided with its tangent. (The differential, dx, of x is the same as Δx when x is the independent variable.) Note that the derivative depends only on the value of x_0, while Δy and dy depend not only on x_0 but on the value of Δx as well. The ratio $\Delta y/\Delta x$ represents the secant slope, and dy/dx the slope of tangent (see Fig. 2.1.104). If Δx is made to approach zero, the secant approaches the tangent as a limiting position, so that the derivative is

$$f'(x) = \frac{dy}{dx} = \lim_{\Delta x \to 0}\left[\frac{\Delta y}{\Delta x}\right] = \lim_{\Delta x \to 0}\left[\frac{f(x_0 + \Delta x) - f(x_0)}{\Delta x}\right]$$

Also, $dy = f'(x)\,dx$.

The symbol "lim" in connection with $\Delta x \to 0$ means "the limit, as Δx approaches 0, of . . ." (A constant c is said to be the **limit** of a variable u if, whenever any quantity m has been assigned, there is a stage in the variation process beyond which $|c - u|$ is always less than m; or, briefly, c is the limit of u if the difference between c and u can be made to become and remain as small as we please.)

To find the derivative of a given function at a given point: (1) If the function is given only by a curve, measure graphically the slope of the tangent at the point in question; (2) if the function is given by a mathematical expression, use the following rules for differentiation. These rules give, directly, the differential, dy, in terms of dx; to find the derivative, dy/dx, divide through by dx.

Rules for Differentiation (Here u, v, w, . . . represent any functions of a variable x, or may themselves be independent variables. a is a constant which does not change in value in the same discussion; $e = 2.71828$.)

1. $d(a + u) = du$
2. $d(au) = a\,du$
3. $d(u + v + w + \cdots) = du + dv + dw + \cdots$
4. $d(uv) = u\,dv + v\,du$
5. $d(uvw\ldots) = (uvw\ldots)\left(\frac{du}{u} + \frac{dv}{v} + \frac{dw}{w} + \cdots\right)$
6. $d\frac{u}{v} = \frac{v\,du - u\,dv}{v^2}$
7. $d(u^m) = mu^{m-1}\,du$. Thus, $d(u^2) = 2u\,du$; $d(u^3) = 3u^2\,du$; etc.
8. $d\sqrt{u} = \frac{du}{2\sqrt{u}}$
9. $d\left(\frac{1}{u}\right) = -\frac{du}{u^2}$
10. $d(e^u) = e^u\,du$
11. $d(a^u) = (\ln a)a^u\,du$
12. $d\ln u = \frac{du}{u}$
13. $d\log_{10} u = \log_{10} e\,\frac{du}{u} = (0.4343\ldots)\frac{du}{u}$
14. $d\sin u = \cos u\,du$
15. $d\csc u = -\cot u \csc u\,du$
16. $d\cos u = -\sin u\,du$
17. $d\sec u = \tan u \sec u\,du$
18. $d\tan u = \sec^2 u\,du$
19. $d\cot u = -\csc^2 u\,du$
20. $d\sin^{-1} u = \frac{du}{\sqrt{1 - u^2}}$
21. $d\csc^{-1} u = -\frac{du}{u\sqrt{u^2 - 1}}$
22. $d\cos^{-1} u = \frac{du}{\sqrt{1 - u^2}}$
23. $d\sec^{-1} u = \frac{du}{u\sqrt{u^2 - 1}}$
24. $d\tan^{-1} u = \frac{du}{1 + u^2}$
25. $d\cot^{-1} u = -\frac{du}{1 + u^2}$
26. $d\ln\sin u = \cot u\,du$
27. $d\ln\tan u = \frac{2\,du}{\sin 2u}$
28. $d\ln\cos u = -\tan u\,du$
29. $d\ln\cot u = -\frac{2\,du}{\sin 2u}$
30. $d\sinh u = \cosh u\,du$
31. $d\,\mathrm{csch}\,u = -\mathrm{csch}\,u \coth u\,du$
32. $d\cosh u = \sinh u\,du$
33. $d\,\mathrm{sech}\,u = -\mathrm{sech}\,u \tanh u\,du$

34. $d \tanh u = \operatorname{sech}^2 u\, du$
35. $d \coth u = -\operatorname{csch}^2 u\, du$
36. $d \sinh^{-1} u = \dfrac{du}{\sqrt{u^2 + 1}}$
37. $d \operatorname{csch}^{-1} u = -\dfrac{du}{u\sqrt{u^2 + 1}}$
38. $d \cosh^{-1} u = \dfrac{du}{\sqrt{u^2 - 1}}$
39. $d \operatorname{sech}^{-1} u = -\dfrac{du}{u\sqrt{1 - u^2}}$
40. $d \tanh^{-1} u = \dfrac{du}{1 - u^2}$
41. $d \coth^{-1} u = \dfrac{du}{1 - u^2}$
42. $d(u^v) = (u^{v-1})(u \ln u\, dv + v\, du)$

Derivatives of Higher Orders The derivative of the derivative is called the second derivative; the derivative of this, the third derivative; and so on. If $y = f(x)$,

$$f'(x) = D_x y = \frac{dy}{dx}$$
$$f''(x) = D_x^2 y = \frac{d^2y}{dx^2}$$
$$f'''(x) = D_x^3 y = \frac{d^3y}{dx^3} \quad \text{etc.}$$

NOTE. If the notation d^2y/dx^2 is used, this must not be treated as a fraction, like dy/dx, but as an inseparable symbol, made up of a symbol of operation d^2/dx^2, and an operand y.

The geometric meaning of the second derivative is this: if the original function $y = f(x)$ is represented by a curve in the usual way, then at any point where $f''(x)$ is *positive*, the curve is *concave upward*, and at any point where $f''(x)$ is *negative*, the curve is *concave downward* (Fig. 2.1.105). When $f''(x) = 0$, the curve usually has a **point of inflection.**

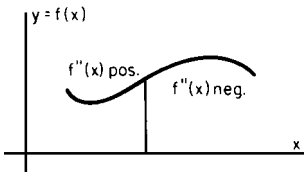

Fig. 2.1.105 Curve showing concavity.

Functions of two or more variables may be denoted by $f(x, y, \ldots)$, $F(x, y, \ldots)$, etc. The derivative of such a function $u = f(x, y, \ldots)$ formed on the assumption that x is the only variable ($y, \ldots$ being regarded for the moment as constants) is called the **partial derivative of u with respect to x**, and is denoted by $f_x(x, y)$ or $D_x u$, or $d_x u/dx$, or $\partial u/\partial x$. Similarly, the partial derivative of u with respect to y is $f_y(x, y)$ or $D_y u$, or $d_y u/dy$, or $\partial u/\partial y$.

NOTE. In the third notation, $d_x u$ denotes the differential of u formed on the assumption that x is the only variable. If the fourth notation, $\partial u/\partial x$, is used, this must not be treated as a fraction like du/dx; the $\partial/\partial x$ is a symbol of operation, operating on u, and the "∂x" must not be separated.

Partial derivatives of the second order are denoted by f_{xx}, f_{xy}, f_{yy}, or by Du, $D_x(D_y u)$, $D_y^2 u$, or by $\partial^2 u/\partial x^2$, $\partial^2 u/\partial x\, \partial y$, $\partial^2 u/\partial y^2$, the last symbols being "inseparable." Similarly for higher derivatives. Note that $f_{xy} = f_{yx}$.

If increments Δx, Δy (or dx, dy) are assigned to the independent variables x, y, the increment, Δu, produced in $u = f(x, y)$ is

$$\Delta u = f(x + \Delta x, y + \Delta y) - f(x, y)$$

while the **differential,** du, i.e., the value which Δu would have if the partial derivatives of u with respect to x and y were constant, is given by

$$du = (f_x) \cdot dx + (f_y) \cdot dy$$

Here the coefficients of dx and dy are the values of the partial derivatives of u at the point in question.

If x and y are functions of a third variable t, then the equation

$$\frac{du}{dt} = (f_x)\frac{dx}{dt} + (f_y)\frac{dy}{dt}$$

expresses the rate of change of u with respect to t, in terms of the separate rate of change of x and y with respect to t.

Implicit Functions If $f(x, y) = 0$, either of the variables x and y is said to be an implicit function of the other. To find dy/dx, either (1) solve for y in terms of x, and then find dy/dx directly; or (2) differentiate the equation through as it stands, remembering that both x and y are variables, and then divide by dx; or (3) use the formula $dy/dx = -(f_x/f_y)$, where f_x and f_y are the partial derivatives of $f(x, y)$ at the point in question.

Maxima and Minima

A **function of one variable,** as $y = f(x)$, is said to have a **maximum** at a point $x = x_0$, if at that point the slope of the curve is zero and the concavity downward (see Fig. 2.1.106); a sufficient condition for a maximum is $f'(x_0) = 0$ and $f''(x_0)$ negative. Similarly, $f(x)$ has a **minimum** if the slope is zero and the concavity upward; a sufficient condition for a minimum is $f'(x_0) = 0$ and $f''(x_0)$ positive. If $f''(x_0) = 0$ and $f'''(x_0) \neq 0$, the point x_0 will be a **point of inflection.** If $f'(x_0) = 0$ and $f''(x_0) = 0$ and $f'''(x_0) = 0$, the point x_0 will be a maximum if $f''''(x_0) < 0$, and a minimum if $f''''(x_0) > 0$. It is usually sufficient, however, in any practical case, to find the values of x which make $f'(x) = 0$, and then decide, from a general knowledge of the curve or the sign of $f'(x)$ to the right and left of x_0, which of these values (if any) give maxima or minima, without investigating the higher derivatives.

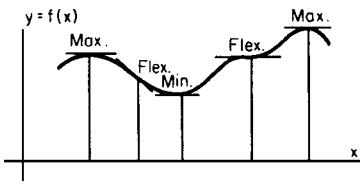

Fig. 2.1.106 Curve showing maxima and minima.

A **function of two variables,** as $u = f(x, y)$, will have a **maximum** at a point (x_0, y_0) if at that point $f_x = 0$, $f_y = 0$, and $f_{xx} < 0$, $f_{yy} < 0$; and a **minimum** if at that point $f_x = 0$, $f_y = 0$, and $f_{xx} > 0$, $f_{yy} > 0$; provided, in each case, $(f_{xx})(f_{yy}) - (f_{xy})^2$ is positive. If $f_x = 0$ and $f_y = 0$, and f_{xx} and f_{yy} have opposite signs, the point (x_0, y_0) will be a "saddle point" of the surface representing the function.

Indeterminate Forms

In the following paragraphs, $f(x)$, $g(x)$ denote functions which approach 0; $F(x)$, $G(x)$ functions which increase indefinitely; and $U(x)$ a function which approaches 1, when x approaches a definite quantity a. The problem in each case is to find the limit approached by certain combinations of these functions when x approaches a. The symbol $\rightarrow$ is to be read "approaches" or "tends to."

CASE 1. "0/0." To find the limit of $f(x)/g(x)$ when $f(x) \rightarrow 0$ and $g(x) \rightarrow 0$, use the theorem that $\lim [f(x)/g(x)] = \lim [f'(x)/g'(x)]$,

where $f'(x)$ and $g'(x)$ are the derivatives of $f(x)$ and $g(x)$. This second limit may be easier to find than the first. If $f'(x) \to 0$ and $g'(x) \to 0$, apply the same theorem a second time: $\lim [f'(x)/g'(x)] = \lim [f''(x)/g''(x)]$, and so on.

CASE 2. "∞/∞." If $F(x) \to \infty$ and $G(x) \to \infty$, then $\lim [F(x)/G(x)] = \lim [F'(x)/G'(x)]$, precisely as in Case 1.

CASE 3. "$0 \cdot \infty$." To find the limit of $f(x) \cdot F(x)$ when $f(x) \to 0$ and $F(x) \to \infty$, write $\lim [f(x) \cdot F(x)] = \lim\{f(x)/[1/F(x)]\}$ or $= \lim \{F(x)/[1/f(x)]\}$, then proceed as in Case 1 or Case 2.

CASE 4. The limit of combinations "0^0" or $[f(x)]^{g(x)}$; "1^∞" or $[U(x)]^{F(x)}$; "∞^0" or $[F(x)]^{b(x)}$ may be found since their logarithms are limits of the type evaluated in Case 3.

CASE 5. "$\infty - \infty$." If $F(x) \to \infty$ and $G(x) \to \infty$, write

$$\lim [F(x) - G(x)] = \lim \frac{1/G(x) - 1/F(x)}{1/[F(x) \cdot G(x)]}$$

then proceed as in Case 1. Sometimes it is shorter to expand the functions in series. It should be carefully noticed that expressions like 0/0, ∞/∞, etc., do not represent mathematical quantities.

Curvature

The **radius of curvature** R of a plane curve at any point P (Fig. 2.1.107) is the distance, measured along the normal, on the concave side of the curve, to the **center of curvature,** C, this point being the limiting position of the point of intersection of the normals at P and a neighboring point Q, as Q is made to approach P along the curve. If the equation of the curve is $y = f(x)$,

$$R = \frac{ds}{du} = \frac{[1 + (y')^2]^{3/2}}{y''}$$

where $ds = \sqrt{dx^2 + dy^2}$ = the differential of arc, $u = \tan^{-1}[f'(x)]$ = the angle which the tangent at P makes with the x axis, and $y' = f'(x)$ and $y'' = f''(x)$ are the first and second derivatives of $f(x)$ at the point P. Note that $dx = ds \cos u$ and $dy = ds \sin u$. The **curvature,** K, at the point P, is $K = 1/R = du/ds$; i.e., the curvature is the rate at which the angle u is changing with respect to the length of arc s. If the slope of the curve is small, $K \approx f''(x)$.

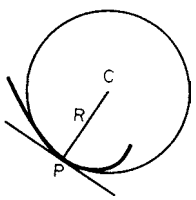

Fig. 2.1.107 Curve showing radius of curvature.

If the equation of the curve in polar coordinates is $r = f(\theta)$, where r = radius vector and θ = polar angle, then

$$R = \frac{[r^2 + (r')^2]^{3/2}}{r^2 - rr'' + 2(r')^2}$$

where $r' = f'(\theta)$ and $r'' = f''(\theta)$.

The **evolute** of a curve is the locus of its centers of curvature. If one curve is the evolute of another, the second is called the **involute** of the first.

Indefinite Integrals

An **integral** of $f(x)\,dx$ is any function whose differential is $f(x)\,dx$, and is denoted by $\int f(x)\,dx$. All the integrals of $f(x)\,dx$ are included in the expression $\int f(x)\,dx + C$, where $\int f(x)\,dx$ is any particular integral, and C is an arbitrary constant. The process of finding (when possible) an integral of a given function consists in recognizing by inspection a function which, when differentiated, will produce the given function; or in transforming the given function into a form in which such recognition is easy. The most common integrable forms are collected in the following brief table; for a more extended list, see Peirce, "Table of Integrals," Ginn, or Dwight, "Table of Integrals and other Mathematical Data," Macmillan, or "CRC Mathematical Tables."

General Formulas

1. $\int a\,du = a \int du = au + C$
2. $\int (u + v)\,dx = \int u\,dx + \int v\,dx$
3. $\int u\,dv = uv - \int v\,du$ (integration by parts)
4. $\int f(x)\,dx = \int f[F(y)]F'(y)\,dy,\ x = F(y)$ (change of variables)
5. $\int dy \int f(x, y)\,dx = \int dx \int f(x, y)\,dy$

Fundamental Integrals

6. $\int x^n\,dx = \frac{x^{n+1}}{n+1} + C$, when $n \neq -1$
7. $\int \frac{dx}{x} = \ln x + C = \ln cx$
8. $\int e^x\,dx = e^x + C$
9. $\int \sin x\,dx = -\cos x + C$
10. $\int \cos x\,dx = \sin x + C$
11. $\int \frac{dx}{\sin^2 x} = \int \csc^2 x\,dx = -\cot x + C$
12. $\int \frac{dx}{\cos^2 x} = \int \sec^2 x\,dx = \tan x + C$
13. $\int \frac{dx}{\sqrt{1 - x^2}} = \sin^{-1} x + C = -\cos^{-1} x + C$
14. $\int \frac{dx}{1 + x^2} = \tan^{-1} x + C = -\cot^{-1} x + C$

Rational Functions

15. $\int (a + bx)^n\,dx = \frac{(a + bx)^{n+1}}{(n+1)b} + C$
16. $\int \frac{dx}{a + bx} = \frac{1}{b} \ln (a + bx) + C = \frac{1}{b} \ln c(a + bx)$
17. $\int \frac{dx}{x^n} = -\frac{1}{(n-1)x^{n-1}} + C$ except when $n = 1$
18. $\int \frac{dx}{(a + bx)^2} = -\frac{1}{b(a + bx)} + C$
19. $\int \frac{dx}{1 - x^2} = \tfrac{1}{2} \ln \frac{1 + x}{1 - x} + C = \tanh^{-1} x + C$, when $x < 1$
20. $\int \frac{dx}{x^2 - 1} = \tfrac{1}{2} \ln \frac{x - 1}{x + 1} + C = -\coth^{-1} x + C$, when $x > 1$
21. $\int \frac{dx}{a + bx^2} = \frac{1}{\sqrt{ab}} \tan^{-1}\left(\sqrt{\frac{b}{a}}x\right) + C$
22. $\int \frac{dx}{a - bx^2} = \frac{1}{2\sqrt{ab}} \ln \frac{\sqrt{ab} + bx}{\sqrt{ab} - bx} + C = \frac{1}{\sqrt{ab}} \tanh^{-1}\left(\sqrt{\frac{b}{a}}x\right) + C$ $[a > 0, b > 0]$

23. $\displaystyle\int \frac{dx}{a+2bx+cx^2} = \left.\begin{aligned} &\frac{1}{\sqrt{ac-b^2}}\tan^{-1}\frac{b+cx}{\sqrt{ac-b^2}}+C \\ &= \frac{1}{2\sqrt{b^2-ac}}\ln\frac{\sqrt{b^2-ac}-b-cx}{\sqrt{b^2-ac}+b+cx}+C \\ &= -\frac{1}{\sqrt{b^2-ac}}\tanh^{-1}\frac{b+cx}{\sqrt{b^2-ac}}+C \end{aligned}\right\}\begin{aligned}&[ac-b^2>0]\\&[b^2-ac>0]\end{aligned}$

24. $\displaystyle\int \frac{dx}{a+2bx+cx^2} = -\frac{1}{b+cx}+C$, when $b^2=ac$

25. $\displaystyle\int \frac{(m+nx)\,dx}{a+2bx+cx^2} = \frac{n}{2c}\ln(a+2bx+cx^2) + \frac{mc-nb}{c}\int\frac{dx}{a+2bx+cx^2}$

26. In $\displaystyle\int \frac{f(x)\,dx}{a+2bx+cx^2}$, if $f(x)$ is a polynomial of higher than the first degree, divide by the denominator before integrating

27. $\displaystyle\int \frac{dx}{(a+2bx+cx^2)^p} = \frac{1}{2(ac-b^2)(p-1)} \times \frac{b+cx}{(a+2bx+cx^2)^{p-1}} + \frac{(2p-3)c}{2(ac-b^2)(p-1)}\int\frac{dx}{(a+2bx+cx^2)^{p-1}}$

28. $\displaystyle\int \frac{(m+nx)\,dx}{(a+2bx+cx^2)^p} = -\frac{n}{2c(p-1)}\times \frac{1}{(a+2bx+cx^2)^{p-1}} + \frac{mc-nb}{c}\int\frac{dx}{(a+2bx+cx^2)^p}$

29. $\displaystyle\int x^{m-1}(a+bx)^n\,dx = \frac{x^{m-1}(a+bx)^{n+1}}{(m+n)b} - \frac{(m-1)a}{(m+n)b}\int x^{m-2}(a+bx)^n\,dx = \frac{x^m(a+bx)^n}{m+n} + \frac{na}{m+n}\int x^{m-1}(a+bx)^{n-1}\,dx$

Irrational Functions

30. $\displaystyle\int \sqrt{a+bx}\,dx = \frac{2}{3b}(\sqrt{a+bx})^3+C$

31. $\displaystyle\int \frac{dx}{\sqrt{a+bx}} = \frac{2}{b}\sqrt{a+bx}+C$

32. $\displaystyle\int \frac{(m+nx)\,dx}{\sqrt{a+bx}} = \frac{2}{3b^2}(3mb-2an+nbx)\sqrt{a+bx}+C$

33. $\displaystyle\int \frac{dx}{(m+nx)\sqrt{a+bx}}$; substitute $y=\sqrt{a+bx}$, and use 21 and 22

34. $\displaystyle\int \frac{f(x,\sqrt[n]{a+bx})}{F(x,\sqrt[n]{a+bx})}\,dx$; substitute $\sqrt[n]{a+bx}=y$

35. $\displaystyle\int \frac{dx}{\sqrt{a^2-x^2}} = \sin^{-1}\frac{x}{a}+C = -\cos^{-1}\frac{x}{a}+C$

36. $\displaystyle\int \frac{dx}{\sqrt{a^2+x^2}} = \ln(x+\sqrt{a^2+x^2})+C = \sinh^{-1}\frac{x}{a}+C$

37. $\displaystyle\int \frac{dx}{\sqrt{x^2-a^2}} = \ln(x+\sqrt{x^2-a^2})+C = \cosh^{-1}\frac{x}{a}+C$

38. $\displaystyle\int \frac{dx}{\sqrt{a+2bx+cx^2}}$
$= \dfrac{1}{\sqrt{c}}\ln(b+cx+\sqrt{c}\sqrt{a+2bx+cx^2})+C$, where $c>0$
$= \dfrac{1}{\sqrt{c}}\sinh^{-1}\dfrac{b+cx}{\sqrt{ac-b^2}}+C$, when $ac-b^2>0$
$= \dfrac{1}{\sqrt{c}}\cosh^{-1}\dfrac{b+cx}{\sqrt{b^2-ac}}+C$, when $b^2-ac>0$
$= \dfrac{-1}{\sqrt{-c}}\sin^{-1}\dfrac{b+cx}{\sqrt{b^2-ac}}+C$, when $c<0$

39. $\displaystyle\int \frac{(m+nx)\,dx}{\sqrt{a+2bx+cx^2}} = \frac{n}{c}\sqrt{a+2bx+cx^2} + \frac{mc-nb}{c}\int\frac{dx}{\sqrt{a+2bx+cx^2}}$

40. $\displaystyle\int \frac{x^m\,dx}{\sqrt{a+2bx+cx^2}} = \frac{x^{m-1}X}{mc} - \frac{(m-1)a}{mc}\int\frac{x^{m-2}\,dx}{X} - \frac{(2m-1)b}{mc}\int\frac{x^{m-1}}{X}\,dx$ when $X=\sqrt{a+2bx+cx^2}$

41. $\displaystyle\int \sqrt{a^2+x^2}\,dx = \frac{x}{2}\sqrt{a^2+x^2}+\frac{a^2}{2}\ln(x+\sqrt{a^2+x^2})+C$
$= \dfrac{x}{2}\sqrt{a^2+x^2}+\dfrac{a^2}{2}\sinh^{-1}\dfrac{x}{a}+C$

42. $\displaystyle\int \sqrt{a^2-x^2}\,dx = \frac{x}{2}\sqrt{a^2-x^2}+\frac{a^2}{2}\sin^{-1}\frac{x}{a}+C$

43. $\displaystyle\int \sqrt{x^2-a^2}\,dx = \frac{x}{2}\sqrt{x^2-a^2}-\frac{a^2}{2}\ln(x+\sqrt{x^2-a^2})+C$
$= \dfrac{x}{2}\sqrt{x^2-a^2}-\dfrac{a^2}{2}\cosh^{-1}\dfrac{x}{a}+C$

44. $\displaystyle\int \sqrt{a+2bx+cx^2}\,dx = \frac{b+cx}{2c}\sqrt{a+2bx+cx^2} + \frac{ac-b^2}{2c}\int\frac{dx}{\sqrt{a+2bx+cx^2}}+C$

Transcendental Functions

45. $\displaystyle\int a^x\,dx = \frac{a^x}{\ln a}+C$

46. $\displaystyle\int x^n e^{ax}\,dx = \frac{x^n e^{ax}}{a}\left[1-\frac{n}{ax}+\frac{n(n-1)}{a^2x^2}-\cdots\pm\frac{n!}{a^n x^n}\right]+C$

47. $\displaystyle\int \ln x\,dx = x\ln x - x + C$

48. $\displaystyle\int \frac{\ln x}{x^2}\,dx = -\frac{\ln x}{x}-\frac{1}{x}+C$

49. $\displaystyle\int \frac{(\ln x)^n}{x}\,dx = \frac{1}{n+1}(\ln x)^{n+1}+C$

50. $\displaystyle\int \sin^2 x\,dx = -\tfrac{1}{4}\sin 2x + \tfrac{1}{2}x + C$
$= -\tfrac{1}{2}\sin x\cos x + \tfrac{1}{2}x + C$

51. $\displaystyle\int \cos^2 x\,dx = \tfrac{1}{4}\sin 2x + \tfrac{1}{2}x + C$
$= \tfrac{1}{2}\sin x\cos x + \tfrac{1}{2}x + C$

52. $\displaystyle\int \sin mx\,dx = -\frac{\cos mx}{m}+C$

53. $\displaystyle\int \cos mx\,dx = \frac{\sin mx}{m}+C$

54. $\displaystyle\int \sin mx\cos nx\,dx = -\frac{\cos(m+n)x}{2(m+n)} - \frac{\cos(m-n)x}{2(m-n)}+C$

55. $\displaystyle\int \sin mx\sin nx\,dx = \frac{\sin(m-n)x}{2(m-n)} - \frac{\sin(m+n)x}{2(m+n)}+C$

56. $\displaystyle\int \cos mx\cos nx\,dx = \frac{\sin(m-n)x}{2(m-n)} + \frac{\sin(m+n)x}{2(m+n)}+C$

57. $\int \tan x\,dx = -\ln \cos x + C$

58. $\int \cot x\,dx = \ln \sin x + C$

59. $\int \frac{dx}{\sin x} = \ln \tan \frac{x}{2} + C$

60. $\int \frac{dx}{\cos x} = \ln \tan \left(\frac{\pi}{4} + \frac{x}{2}\right) + C$

61. $\int \frac{dx}{1 + \cos x} = \tan \frac{x}{2} + C$

62. $\int \frac{dx}{1 - \cos x} = -\cot \frac{x}{2} + C$

63. $\int \sin x \cos x\,dx = \tfrac{1}{2} \sin^2 x + C$

64. $\int \frac{dx}{\sin x \cos x} = \ln \tan x + C$

65.* $\int \sin^n x\,dx = -\frac{\cos x \sin^{n-1} x}{n} + \frac{n-1}{n} \int \sin^{n-2} x\,dx$

66.* $\int \cos^n x\,dx = \frac{\sin x \cos^{n-1} x}{n} + \frac{n-1}{n} \int \cos^{n-2} x\,dx$

67. $\int \tan^n x\,dx = \frac{\tan^{n-1} x}{n-1} - \int \tan^{n-2} x\,dx$

68. $\int \cot^n x\,dx = -\frac{\cot^{n-1} x}{n-1} - \int \cot^{n-2} x\,dx$

69. $\int \frac{dx}{\sin^n x} = -\frac{\cos x}{(n-1)\sin^{n-1} x} + \frac{n-2}{n-1} \int \frac{dx}{\sin^{n-2} x}$

70. $\int \frac{dx}{\cos^n x} = \frac{\sin x}{(n-1)\cos^{n-1} x} + \frac{n-2}{n-1} \int \frac{dx}{\cos^{n-2} x}$

71.† $\int \sin^p x \cos^q x\,dx = \frac{\sin^{p+1} x \cos^{q-1} x}{p+q} + \frac{q-1}{p+q} \int \sin^p x \cos^{q-2} x\,dx = -\frac{\sin^{p-1} x \cos^{q+1} x}{p+q} + \frac{p-1}{p+q} \int \sin^{p-2} x \cos^q x\,dx$

72.† $\int \sin^{-p} x \cos^q x\,dx = -\frac{\sin^{-p+1} x \cos^{q+1} x}{p-1} + \frac{p-q-2}{p-1} \int \sin^{-p+2} x \cos^q x\,dx$

73.† $\int \sin^p x \cos^{-q} x\,dx = \frac{\sin^{p+1} x \cos^{-q+1} x}{q-1} + \frac{q-p-2}{q-1} \int \sin^p x \cos^{-q+2} x\,dx$

74. $\int \frac{dx}{a + b\cos x} = \frac{2}{\sqrt{a^2 - b^2}} \tan^{-1}\left(\sqrt{\frac{a-b}{a+b}} \tan \tfrac{1}{2}x\right) + C,$ when $a^2 > b^2$,

$= \frac{1}{\sqrt{b^2 - a^2}} \ln \frac{b + a\cos x + \sin x\sqrt{b^2 - a^2}}{a + b\cos x} + C,$ when $a^2 < b^2$,

$= \frac{2}{\sqrt{b^2 - a^2}} \tanh^{-1}\left(\sqrt{\frac{b-a}{b+a}} \tan \tfrac{1}{2}x\right) + C,$ when $a^2 < b^2$

75. $\int \frac{\cos x\,dx}{a + b\cos x} = \frac{x}{b} - \frac{a}{b} \int \frac{dx}{a + b\cos x} + C$

76. $\int \frac{\sin x\,dx}{a + b\cos x} = -\frac{1}{b} \ln (a + b\cos x) + C$

* If n is an odd number, substitute $\cos x = z$ or $\sin x = z$.
† If p or q is an odd number, substitute $\cos x = z$ or $\sin x = z$.

77. $\int \frac{A + B\cos x + C\sin x}{a + b\cos x + c\sin x} dx = A \int \frac{dy}{a + p\cos y} + (B\cos u + C\sin u) \int \frac{\cos y\,dy}{a + p\cos y} - (B\sin u - C\cos u) \int \frac{\sin y\,dy}{a + p\cos y},$ where $b = p\cos u$, $c = p\sin u$ and $x - u = y$

78. $\int e^{ax} \sin bx\,dx = \frac{a\sin bx - b\cos bx}{a^2 + b^2} e^{ax} + C$

79. $\int e^{ax} \cos bx\,dx = \frac{a\cos bx + b\sin bx}{a^2 + b^2} e^{ax} + C$

80. $\int \sin^{-1} x\,dx = x\sin^{-1} x + \sqrt{1 - x^2} + C$

81. $\int \cos^{-1} x\,dx = x\cos^{-1} x - \sqrt{1 - x^2} + C$

82. $\int \tan^{-1} x\,dx = x\tan^{-1} x - \tfrac{1}{2}\ln(1 + x^2) + C$

83. $\int \cot^{-1} x\,dx = x\cot^{-1} x + \tfrac{1}{2}\ln(1 + x^2) + C$

84. $\int \sinh x\,dx = \cosh x + C$

85. $\int \tanh x\,dx = \ln \cosh x + C$

86. $\int \cosh x\,dx = \sinh x + C$

87. $\int \coth x\,dx = \ln \sinh x + C$

88. $\int \operatorname{sech} x\,dx = 2\tan^{-1}(e^x) + C$

89. $\int \operatorname{csch} x\,dx = \ln \tanh(x/2) + C$

90. $\int \sinh^2 x\,dx = \tfrac{1}{2}\sinh x \cosh x - \tfrac{1}{2}x + C$

91. $\int \cosh^2 x\,dx = \tfrac{1}{2}\sinh x \cosh x + \tfrac{1}{2}x + C$

92. $\int \operatorname{sech}^2 x\,dx = \tanh x + C$

93. $\int \operatorname{csch}^2 x\,dx = -\coth x + C$

Hints on Using Integral Tables It happens with frustrating frequency that no integral table lists the integral that needs to be evaluated. When this happens, one may (a) seek a more complete integral table, (b) appeal to mathematical software, such as Mathematica, Maple, MathCad or Derive, (c) use numerical or approximate methods, such as Simpson's rule (see section "Numerical Methods"), or (d) attempt to transform the integral into one which may be evaluated. Some hints on such transformation follow. For a more complete list and more complete explanations, consult a calculus text, such as Thomas, "Calculus and Analytic Geometry," Addison-Wesley, or Anton, "Calculus with Analytic Geometry," Wiley. One or more of the following "tricks" may be successful.

TRIGONOMETRIC SUBSTITUTIONS

1. If an integrand contains $\sqrt{(a^2 - x^2)}$, substitute $x = a\sin u$, and $\sqrt{(a^2 - x^2)} = a\cos u$.
2. Substitute $x = a\tan u$ and $\sqrt{(x^2 + a^2)} = a\sec u$.
3. Substitute $x = a\sec u$ and $\sqrt{(x^2 - a^2)} = a\tan u$.

COMPLETING THE SQUARE

4. Rewrite $ax^2 + bx + c = a[x + b/(2a)]^2 + (4ac - b^2)/(4a)$; then substitute $u = x + b/(2a)$ and $B = (4ac - b^2)/(4a)$.

PARTIAL FRACTIONS

5. For a ratio of polynomials, where the denominator has been completely factored into linear factors $p_i(x)$ and quadratic factors $q_j(x)$, and where the degree of the numerator is less than the degree of the denominator, then rewrite $r(x)/[p_1(x) \cdots p_n(x)q_1(x) \cdots q_m(x)] = A_1/p_1(x) + \cdots + A_n/p_n(x) + (B_1x + C_1)/q_1(x) + \cdots + (B_mx + C_m)/q_m(x)$.

INTEGRATION BY PARTS

6. Change the integral using the formula

$$\int u\,dv = uv - \int v\,du$$

where u and dv are chosen so that (a) v is easy to find from dv, and (b) $v\,du$ is easier to find than $u\,dv$.

Kasube suggests ("A Technique for Integration by Parts," *Am. Math. Month.*, vol. 90, no. 3, Mar. 1983): Choose u in the order of preference LIATE, that is, Logarithmic, Inverse trigonometric, Algebraic, Trigonometric, Exponential.

EXAMPLE. Find $\int x \ln x\,dx$. The logarithmic $\ln x$ has higher priority than does the algebraic x, so let $u = \ln(x)$ and $dv = x\,dx$. Then $du = (1/x)\,dx$; $v = x^2/2$, so $\int x \ln x\,dx = uv - \int v\,du = (x^2/2)\ln x - \int (x^2/2)(1/x)\,dx = (x^2/2)\ln x - \int x/2\,dx = (x^2/2)\ln x - x^2/4 + C$.

Definite Integrals The definite integral of $f(x)\,dx$ from $x = a$ to $x = b$, denoted by $\int_a^b f(x)\,dx$, is the limit (as n increases indefinitely) of a sum of n terms:

$$\int_a^b f(x)\,dx = \lim_{n\to\infty} [f(x_1)\,\Delta x + f(x_2)\,\Delta x + f(x_3)\,\Delta x + \cdots + f(x_n)\Delta x]$$

built up as follows: Divide the interval from a to b into n equal parts, and call each part $\Delta x, = (b - a)/n$; in each of these intervals take a value of x (say, $x_1, x_2, \ldots, x_n$), find the value of the function $f(x)$ at each of these points, and multiply it by Δx, the width of the interval; then take the limit of the sum of the terms thus formed, when the number of terms increases indefinitely, while each individual term approaches zero.

Geometrically, $\int_a^b f(x)\,dx$ is the area bounded by the curve $y = f(x)$, the x axis, and the ordinates $x = a$ and $x = b$ (Fig. 2.1.108); i.e., briefly, the "area under the curve, from a to b." The **fundamental theorem** for the evaluation of a definite integral is the following:

$$\int_a^b f(x)\,dx = \left[\int f(x)\,dx\right]_{x=b} - \left[\int f(x)\,dx\right]_{x=a}$$

i.e., the definite integral is equal to the difference between two values of any one of the indefinite integrals of the function in question. In other words, the limit of a sum can be found whenever the function can be integrated.

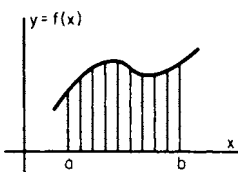

Fig. 2.1.108 Graph showing areas to be summed during integration.

Properties of Definite Integrals

$$\int_a^b = -\int_b^a; \qquad \int_a^c + \int_c^b = \int_a^b$$

MEAN-VALUE THEOREM FOR INTEGRALS

$$\int_a^b F(x)f(x)\,dx = F(X)\int_a^b f(x)\,dx$$

provided $f(x)$ does not change sign from $x = a$ to $x = b$; here X is some (unknown) value of x intermediate between a and b.

MEAN VALUE. The **mean value** of $f(x)$ with respect to x, between a and b, is

$$\bar{f} = \frac{1}{b-a}\int_a^b f(x)\,dx$$

THEOREM ON CHANGE OF VARIABLE. In evaluating $\int_{x=a}^{x=b} f(x)\,dx$, $f(x)\,dx$ may be replaced by its value in terms of a new variable t and dt, and $x = a$ and $x = b$ by the corresponding values of t, provided that throughout the interval the relation between x and t is a one-to-one correspondence (i.e., to each value of x there corresponds one and only one value of t, and to each value of t there corresponds one and only one value of x). So $\int_{x=a}^{x=b} f(x)\,dx = \int_{t=g(a)}^{t=g(b)} f(g(t))\,g'(t)\,dt$.

DIFFERENTIATION WITH RESPECT TO THE UPPER LIMIT. If b is variable, then $\int_a^b f(x)\,dx$ is a function b, whose derivative is

$$\frac{d}{db}\int_a^b f(x)\,dx = f(b)$$

DIFFERENTIATION WITH RESPECT TO A PARAMETER

$$\frac{\partial}{\partial c}\int_a^b f(x,c)\,dx = \int_a^b \frac{\partial f(x,c)}{\partial c}\,dx$$

Functions Defined by Definite Integrals The following definite integrals have received special names:

1. Elliptic integral of the first kind $= F(u,k) = \int_0^u \frac{dx}{\sqrt{1 - k^2\sin^2 x}}$

when $k^2 < 1$.

2. Elliptic integral of the second kind $= E(u,k) = \int_0^u \sqrt{1 - k^2\sin^2 x}\,dx$, when $k^2 < 1$.

3, 4. Complete elliptic integrals of the first and second kinds; put $u = \pi/2$ in (1) and (2).

5. The probability integral $= \frac{2}{\sqrt{\pi}}\int_0^x e^{-x^2}\,dx$.

6. The gamma function $= \Gamma(n) = \int_0^\infty x^{n-1}e^{-x}\,dx$.

Approximate Methods of Integration. Mechanical Quadrature (See also section "Numerical Methods.")

1. Use Simpson's rule (see also Scarborough, "Numerical Mathematical Analyses," Johns Hopkins Press).

2. Expand the function in a converging power series, and integrate term by term.

3. Plot the area under the curve $y = f(x)$ from $x = a$ to $x = b$ on squared paper, and measure this area roughly by "counting squares."

Double Integrals The notation $\int\int f(x,y)\,dy\,dx$ means $\int[\int f(x,y)\,dy]\,dx$, the limits of integration in the inner, or first, integral being functions of x (or constants).

EXAMPLE. To find the weight of a plane area whose density, w, is variable, say $w = f(x, y)$. The weight of a typical element, $dx\,dy$, is $f(x, y)\,dx\,dy$. Keeping x and dx constant and summing these elements from, say, $y = F_1(x)$ to $y = F_2(x)$, as determined by the shape of the boundary (Fig. 2.1.109), the weight of a typical strip perpendicular to the x axis is

$$dx \int_{y=F_1(x)}^{y=F_2(x)} f(x, y)\,dy$$

Finally, summing these strips from, say, $x = a$ to $x = b$, the weight of the whole area is

$$\int_{x=a}^{x=b} \left[dx \int_{y=F_1(x)}^{y=F_2(x)} f(x, y)\,dy \right] \text{ or, briefly, } \int\int f(x, y)\,dy\,dx$$

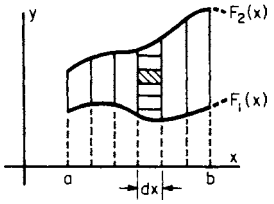

Fig. 2.1.109 Graph showing areas to be summed during double integration.

Triple Integrals The notation $\int\int\int f(x, y, z)\,dz\,dy\,dx$ means

$$\int \left\{ \int \left[\int f(x, y, z)\,dz \right] dy \right\} dx$$

Such integrals are known as **volume integrals.**

EXAMPLE. To find the mass of a volume which has variable density, say, $w = f(x, y, z)$. If the shape of the volume is described by $a < x < b$, $F_1(x) < y < F_2(x)$, and $G_1(x, y) < z < G_2(x, y)$, then the mass is given by

$$\int_a^b \int_{F_1(x)}^{F_2(x)} \int_{G_1(x,y)}^{G_2(x,y)} f(x, y, z)\,dz\,dy\,dx$$

SERIES AND SEQUENCES

Sequences

A **sequence** is an ordered list of numbers, $x_1, x_2, \ldots, x_n, \ldots$.

An infinite sequence is an infinitely long list. A sequence is often defined by a function $f(n)$, $n = 1, 2, \ldots$. The formula defining $f(n)$ is called the **general term** of the sequence.

The variable n is called the **index** of the sequence. Sometimes the index is taken to start with $n = 0$ instead of $n = 1$.

A sequence **converges** to a limit L if the general term $f(n)$ has limit L as n goes to infinity. If a sequence does not have a unique limit, the sequence is said to "diverge." There are two fundamental ways a function can diverge: (1) It may become infinitely large, in which case the sequence is said to be "unbounded," or (2) it may tend to alternate among two or more values, as in the sequence $x_n = (-1)^n$.

A sequence **alternates** if its odd-numbered terms are positive and its even-numbered terms are negative, or vice versa.

Series

A **series** is a sequence of sums. The terms of the sums are another sequence, $x_1, x_2, \ldots$. Then the series is the sequence defined by $s_n = x_1 + x_2 + \cdots + x_n = \sum_{i=1}^{n} x_i$. The sequence s_n is also called the **sequence of partial sums** of the series.

If the sequence of partial sums converges (resp. diverges), then the series is said to converge (resp. diverge). If the limit of a series is S, then the sequence defined by $r_n = S - s_n$ is called the "error sequence" or the "sequence of truncation errors."

Convergence of Series THEOREM. If a series $s_n = x_1 + x_2 + \cdots + x_n$ converges, then it is necessary (but not sufficient) that the sequence x_n has limit zero. A series of partial sums of an alternating sequence is called an *alternating series.*

THEOREM. An alternating series converges whenever the sequence x_n has limit zero.

A series is a **geometric series** if its terms are of the form ar^n. The value r is called the **ratio** of the series. Usually, for geometric series, the index is taken to start with $n = 0$ instead of $n = 1$.

THEOREM. A geometric series with $x_n = ar^n$, $n = 0, 1, 2, \ldots$, converges if and only if $-1 < r < 1$, and then the limit of the series is $a/(1 - r)$. The partial sums of a geometric series are $s_n = a(1 - r^n)/(1 - r)$.

The series defined by the sequence $x_n = 1/n$, $n = 1, 2, \ldots$, is called the **harmonic series.** The harmonic series diverges.

A series with each term $x_n > 0$ is called a "positive series."

There are a number of tests to determine whether or not a positive series s_n converges.

1. *Comparison test.* If $c_1 + c_2 + \cdots + c_n$ is a positive series that converges, and if $0 < x_n < c_n$, then the series $x_1 + x_2 + \cdots + x_n$ also converges.

If $d_1 + d_2 + \cdots + d_n$ diverges and $x_n > d_n$, then $x_1 + x_2 + \cdots + x_n$ also diverges.

2. *Integral test.* If $f(t)$ is a strictly decreasing function and $f(n) = x_n$, then the series s_n and the integral $\int_1^\infty f(t)\,dt$ either both converge or both diverge.

3. *P test.* The series defined by $x_n = 1/n^p$ converges if $p > 1$ and diverges if $p = 1$ or $p < 1$. If $p = 1$, then this is the harmonic series.

4. *Ratio test.* If the limit of the sequence $x_{n+1}/x_n = r$, then the series diverges if $r > 1$, and it converges if $0 < r < 1$. The test is inconclusive if $r = 1$.

5. *Cauchy root test.* If L is the limit of the nth root of the nth term, $\lim x_n^{1/n}$, then the series converges if $L < 1$ and diverges if $L > 1$. If $L = 1$, then the test is inconclusive.

A **power series** is an expression of the form $a_0 + a_1x + a_2x^2 + \cdots + a_nx^n + \cdots$ or $\sum_{i=0}^{\infty} a_ix^i$.

The range of values of x for which a power series converges is the **interval of convergence** of the power series.

General Formulas of Maclaurin and Taylor If $f(x)$ and all its derivatives are continuous in the neighborhood of the point $x = 0$ (or $x = a$), then, for any value of x in this neighborhood, the function $f(x)$ may be expressed as a power series arranged according to ascending powers of x (or of $x - a$), as follows:

$$f(x) = f(0) + \frac{f'(0)}{1!}x + \frac{f''(0)}{2!}x^2 + \frac{f'''(0)}{3!}x^3 + \cdots + \frac{f^{(n-1)}(0)}{(n-1)!}x^{n-1} + (P_n)x^n \qquad \text{(Maclaurin)}$$

$$f(x) = f(a) + \frac{f'(a)}{1!}(x - a) + \frac{f''(a)}{2!}(x - a)^2 + \frac{f'''(a)}{3!}(x - a)^3 + \cdots + \frac{f^{(n-1)}(a)}{(n-1)!}(x - a)^{n-1} + (Q_n)(x - a)^n \qquad \text{(Taylor)}$$

Here $(P_n)x^n$, or $(Q_n)(x - a)^n$, is called the **remainder term;** the values of the coefficients P_n and Q_n may be expressed as follows:

$$P_n = [f^{(n)}(sx)]/n! = [(1 - t)^{n-1}f^{(n)}(tx)]/(n - 1)!$$
$$Q_n = \{f^{(n)}[a + s(x - a)]\}/n!$$
$$= \{(1 - t)^{n-1}f^{(n)}[a + t(x - a)]\}/(n - 1)!$$

where s and t are certain unknown numbers between 0 and 1; the s form is due to Lagrange, the t form to Cauchy.

The error due to neglecting the remainder term is less than $(\overline{P}_n)x^n$, or $(\overline{Q}_n)(x - a)^n$, where $\overline{P}_n$, or $\overline{Q}_n$, is the largest value taken on by P_n, or

Q_n, when s or t ranges from 0 to 1. If this error, which depends on both n and x, approaches 0 as n increases (for any given value of x), then the general expression with remainder becomes (for that value of x) a convergent infinite series.

The sum of the first few terms of Maclaurin's series gives a good approximation to $f(x)$ for values of x near $x = 0$; Taylor's series gives a similar approximation for values near $x = a$.

The MacLaurin series of some important functions are given below.

Power series may be differentiated term by term, so the derivative of a power series $a_0 + a_1x + a_2x^2 + \cdots + a_nx^n$ is $a_1 + 2a_2x + \cdots + na_xx^{n-1} \ldots$. The power series of the derivative has the same interval of convergence, except that the endpoints may or may not be included in the interval.

Series Expansions of Some Important Functions

The range of values of x for which each of the series is convergent is stated at the right of the series.

Geometrical Series

$$\frac{1}{1-x} = \sum_{n=0}^{\infty} x^n \qquad -1 < x < 1$$

$$\frac{1}{(1-x)^m} = 1 + \sum_{n=1}^{\infty} \frac{(m+n-1)!}{(m-1)!n!}x^n \qquad -1 < x < 1$$

Exponential and Logarithmic Series

$$e^x = 1 + \frac{x}{1!} + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \cdots \qquad [-\infty < x < +\infty]$$

$$a^x = e^{mx} = 1 + \frac{m}{1!}x + \frac{m^2}{2!}x^2 + \frac{m^3}{3!}x^3 + \cdots \qquad [a > 0, -\infty < x < +\infty]$$

where $m = \ln a = (2.3026)(\log_{10} a)$.

$$\ln(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5} \cdots \qquad [-1 < x < +1]$$

$$\ln(1-x) = -x - \frac{x^2}{2} - \frac{x^3}{3} - \frac{x^4}{4} - \frac{x^5}{5} - \cdots \qquad [-1 < x < +1]$$

$$\ln\left(\frac{1+x}{1-x}\right) = 2\left(x + \frac{x^3}{3} + \frac{x^5}{5} + \frac{x^7}{7} + \cdots\right) \qquad [-1 < x < +1]$$

$$\ln\left(\frac{x+1}{x-1}\right) = 2\left(\frac{1}{x} + \frac{1}{3x^3} + \frac{1}{5x^5} + \frac{1}{7x^7} + \cdots\right) \qquad [x < -1 \text{ or } +1 < x]$$

$$\ln x = 2\left[\frac{x-1}{x+1} + \frac{1}{3}\left(\frac{x-1}{x+1}\right)^3 + \frac{1}{5}\left(\frac{x-1}{x+1}\right)^5 + \cdots\right] \qquad [0 < x < \infty]$$

$$\ln(a+x) = \ln a + 2\left[\frac{x}{2a+x} + \frac{1}{3}\left(\frac{x}{2a+x}\right)^3 + \frac{1}{5}\left(\frac{x}{2a+x}\right)^5 + \cdots\right] \qquad [0 < a < +\infty, -a < x < +\infty]$$

Series for the Trigonometric Functions In the following formulas, *all angles must be expressed in radians.* If D = the number of degrees in the angle, and x = its radian measure, then $x = 0.017453D$.

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \cdots \qquad [-\infty < x < +\infty]$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \frac{x^8}{8!} - \cdots \qquad [-\infty < x < +\infty]$$

$$\tan x = x + \frac{x^3}{3} + \frac{2x^5}{15} + \frac{17x^7}{315} + \frac{62x^9}{2835} + \cdots \qquad [-\pi/2 < x < +\pi/2]$$

$$\cot x = \frac{1}{x} - \frac{x}{3} - \frac{x^3}{45} - \frac{2x^5}{945} - \frac{x^7}{4725} - \cdots \qquad [-\pi < x < +\pi]$$

$$\sin^{-1} y = y + \frac{y^3}{6} + \frac{3y^5}{40} + \frac{5y^7}{112} + \cdots \qquad [-1 \le y \le +1]$$

$$\tan^{-1} y = y - \frac{y^3}{3} + \frac{y^5}{5} - \frac{y^7}{7} + \cdots \qquad [-1 \le y \le +1]$$

$$\cos^{-1} y = \tfrac{1}{2}\pi - \sin^{-1} y; \qquad \cot^{-1} y = \tfrac{1}{2}\pi - \tan^{-1} y.$$

Series for the Hyperbolic Functions (x a pure number)

$$\sinh x = x + \frac{x^3}{3!} + \frac{x^5}{5!} + \frac{x^7}{7!} + \cdots \qquad [-\infty < x < \infty]$$

$$\cosh x = 1 + \frac{x^2}{2!} + \frac{x^4}{4!} + \frac{x^6}{6!} + \cdots \qquad [-\infty < x < \infty]$$

$$\sinh^{-1} y = y - \frac{y^3}{6} + \frac{3y^5}{40} - \frac{5y^7}{112} + \cdots \qquad [-1 < y < +1]$$

$$\tanh^{-1} y = y + \frac{y^3}{3} + \frac{y^5}{5} + \frac{y^7}{7} + \cdots \qquad [-1 < y < +1]$$

ORDINARY DIFFERENTIAL EQUATIONS

An **ordinary differential equation** is one which contains a single independent variable, or argument, and a single dependent variable, or function, with its derivatives of various orders. A **partial differential equation** is one which contains a function of several independent variables, and its partial derivatives of various orders. The order of a differential equation is the order of the highest derivative which occurs in it. A solution of a differential equation is any relation among the variables, involving no derivatives, though possibly involving integrations which, when substituted in the given equation, will satisfy it. The general solution of an ordinary differential equation of the nth order will contain n arbitrary constants.

If specific values of the arbitrary constants are chosen, then a solution is called a **particular solution.** For most problems, all possible particular solutions to a differential equation may be found by choosing values for the constants in a general solution. In some cases, however, other solutions exist. These are called **singular solutions.**

EXAMPLE. The differential equation $(yy')^2 - a^2 - y^2 = 0$ has general solution $(x-c)^2 + y^2 = a^2$, where c is an arbitrary constant. Additionally, it has the two singular solutions $y = a$ and $y = -a$. The singular solutions form two parallel lines tangent to the family of circles given by the general solution.

The example illustrates a general property of singular solutions; at each point on a singular solution, the singular solution is tangent to some curve given in the general solution.

Methods of Solving Ordinary Differential Equations

DIFFERENTIAL EQUATIONS OF THE FIRST ORDER

1. If possible, separate the variables; i.e., collect all the x's and dx on one side, and all the y's and dy on the other side; then integrate both sides, and add the constant of integration.

2. If the equation is homogeneous in x and y, the value of dy/dx in terms of x and y will be of the form $dy/dx = f(y/x)$. Substituting $y = xt$ will enable the variables to be separated.

Solution: $\log_e x = \int \frac{dt}{f(t) - t} + C.$

3. The expression $f(x, y)\,dx + F(x, y)\,dy$ is an *exact differential* if $\dfrac{\partial f(x, y)}{\partial y} = \dfrac{\partial F(x, y)}{\partial x}$ $(= P$, say). In this case the solution of $f(x, y)\,dx + F(x, y)\,dy = 0$ is

$$\int f(x, y)\,dx + \int [F(x, y) - \int P\,dx]\,dy = C$$

or

$$\int F(x, y)\,dy + \int [f(x, y) - \int P\,dy]\,dx = C$$

4. Linear differential equation of the first order: $\dfrac{dx}{dt} + f(x) \cdot y = F(x)$.

Solution: $y = e^{-P}[\int e^{P} F(x)\,dx + C]$, where $P = \int f(x)\,dx$

5. Bernoulli's equation: $\dfrac{dy}{dx} + f(x) \cdot y = F(x) \cdot y^n$. Substituting $y^{1-n} = v$ gives $(dv/dx) + (1 - n)f(x) \cdot v = (1 - n)F(x)$, which is linear in v and x.

6. Clairaut's equation: $y = xp + f(p)$, where $p = dy/dx$. The solution consists of the family of lines given by $y = Cx + f(C)$, where C is any constant, together with the curve obtained by eliminating p between the equations $y = xp + f(p)$ and $x + f'(p) = 0$, where $f'(p)$ is the derivative of $f(p)$.

7. Riccati's equation. $p + ay^2 + Q(x)y + R(x) = 0$, where $p = dy/dx$ can be reduced to a second-order linear differential equation $(d^2u/dx^2) + Q(x)(du/dx) + R(x) = 0$ by the substitution $y = du/dx$.

8. Homogeneous equations. A function $f(x, y)$ is **homogeneous** of degree n if $f(rx, ry) = r^n f(x, y)$, for all values of r, x, and y. In practice, this means that $f(x, y)$ looks like a polynomial in the two variables x and y, and each term of the polynomial has total degree m. A differential equation is homogeneous if it has the form $f(x, y) = 0$, with f homogeneous. $(xy + x^2)\,dx + y^2\,dy = 0$ is homogeneous. Cos $(xy)\,dx + y^2\,dy = 0$ is not.

If an equation is homogeneous, then either of the substitutions $y = vx$ or $x = vy$ will transform the equation into a separable equation.

9. $dy/dx = f[(ax + by + c)/(dx + ey + g)]$ is reduced to a homogeneous equation by substituting $u = ax + by + c$, $v = dx + ey + g$, if $ae - bd = 0$, and $z = ax + by$, $w = dx + ey$ if $ae - bd = 0$.

Differential Equations of the Second Order

10. *Dependent variable missing.* If an equation does not involve the variable y, and is of the form $F(x, dy/dx, d^2y/dx^2) = 0$, then it can be reduced to a first-order equation by substituting $p = dy/dx$ and $dp/dx = d^2y/dx^2$.

11. *Independent variable missing.* If the equation is of the form $F(y, dy/dx, d^2y/dx^2) = 0$, and so is missing the variable x, then it can be reduced to a first-order equation by substituting $p = dy/dx$ and $p(dp/dy) = d^2y/dx^2$.

12. $\dfrac{d^2y}{dx^2} = -n^2y$.

Solution: $y = C_1 \sin(nx + C_2)$, or $y = C_3 \sin nx + C_4 \cos nx$.

13. $\dfrac{d^2y}{dx^2} = +n^2y$.

Solution: $y = C_1 \sinh(nx + C_2)$, or $y = C_3\,e^{nx} + C_4 e^{-nx}$.

14. $\dfrac{d^2y}{dx^2} = f(y)$.

Solution: $x = \displaystyle\int \frac{dy}{\sqrt{C_1 + 2P}} + C_2$, where $P = \int f(y)\,dy$.

15. $\dfrac{d^2y}{dx^2} = f(x)$.

Solution: $y = \displaystyle\int P\,dx + C_1x + C_2$ where $P = \int f(x)\,dx$,

or $y = xP - \displaystyle\int xf(x)\,dx + C_1x + C_2$.

16. $\dfrac{d^2y}{dx^2} = f\left(\dfrac{dy}{dx}\right)$. Putting $\dfrac{dy}{dx} = z$, $\dfrac{d^2y}{dx^2} = \dfrac{dz}{dx}$,

$$x = \int \frac{dz}{f(z)} + C_1, \quad \text{and} \quad y = \int \frac{z\,dz}{f(z)} + C_2$$

then eliminate z from these two equations.

17. The equation for damped vibrations: $\dfrac{d^2y}{dx^2} + 2b\dfrac{dy}{dx} + a^2y = 0$.

Case 1. If $a^2 - b^2 > 0$, let $m = \sqrt{a^2 - b^2}$.

Solution:

$y = C_1e^{-bx} \sin(mx + C_2)$ or $y = e^{-bx}[C_3 \sin(mx) + C_4 \cos(mx)]$

Case 2. If $a^2 - b^2 = 0$, solution is $y = e^{-bx}(C_1 + C_2x)$.

Case 3. If $a^2 - b^2 < 0$, let $n = \sqrt{b^2 - a^2}$.

Solution:

$y = C_1e^{-bx} \sinh(nx + C_2)$ or $y = C_3e^{-(b+n)x} + C_4e^{-(b-n)x}$

18. $\dfrac{d^2y}{dx^2} + 2b\dfrac{dy}{dx} + a^2y = c$.

Solution: $y = \dfrac{c}{a^2} + y_1$, where y_1 = the solution of the corresponding equation with second member zero [see type 17 above].

19. $\dfrac{d^2y}{dx^2} + 2b\dfrac{dy}{dx} + a^2y = c \sin(kx)$.

Solution: $y = R \sin(kx - S) + y_1$

where $R = c/\sqrt{(a^2 - k^2)^2 + 4b^2k^2}$, $\tan S = 2bk/(a^2 - k^2)$, and y_1 = the solution of the corresponding equation with second member zero [see type 17 above].

20. $\dfrac{d^2y}{dx^2} + 2b\dfrac{dy}{dx} + a^2y = f(x)$.

Solution: $y = R \sin(kx - S) + y_1$

where $R = c/\sqrt{(a^2 - k^2)^2 + 4b^2k^2}$, $\tan S = 2bk/(a^2 - k^2)$, and y_1 = the solution of the corresponding equation with second member zero [see type 17 above].

If $b^2 < a^2$,

$$y_0 = \frac{1}{2\sqrt{b^2 - a^2}}\left[e^{m_1x}\int e^{-m_1x}f(x)\,dx - e^{m_2x}\int e^{-m_2x}f(x)\,dx\right]$$

where $m_1 = -b + \sqrt{b^2 - a^2}$ and $m_2 = -b - \sqrt{b^2 - a^2}$.

If $b^2 < a^2$, let $m = \sqrt{a^2 - b^2}$, then

$$y_0 = \frac{1}{m}e^{-bx}\left[\sin(mx)\int e^{bx}\cos(mx)\cdot f(x)\,dx - \cos(mx)\int e^{bx}\sin(mx)\cdot f(x)\,dx\right]$$

If $b^2 = a^2$, $y_0 = e^{-bx}\left[x\displaystyle\int e^{bx}f(x)\,dx - \int x \cdot e^{bx}f(x)\,dx\right]$.

Types 17 to 20 are examples of linear differential equations with constant coefficients. The solutions of such equations are often found most simply by the use of Laplace transforms. (See Franklin, "Fourier Methods," pp. 198–229, McGraw-Hill or Kreyszig, "Advanced Engineering Mathematics," Wiley.)

Linear Equations

For the linear equation of the nth order

$$A_n(x)\,d^ny/dx^n + A_{n-1}(x)\,d^{n-1}y/dx^{n-1} + \cdots + A_1(x)dy/dx + A_0(x)y = E(x)$$

the general solution is $y = u + c_1u_1 + c_2u_2 + \cdots + c_nu_n$. Here u, the particular integral, is any solution of the given equation, and $u_1, u_2, \ldots, u_n$ form a fundamental system of solutions of the homogeneous equation obtained by replacing $E(x)$ by zero. A set of solutions is fundamental, or independent, if its Wronskian determinant $W(x)$ is not

zero, where

$$W(x) = \begin{vmatrix} u_1 & u_2 & \cdots & u_n \\ u_1' & u_2' & \cdots & u_n' \\ \cdot & \cdot & \cdots & \cdot \\ \cdot & \cdot & \cdots & \cdot \\ \cdot & \cdot & \cdots & \cdot \\ u_1^{(n-1)} & u_2^{(n-1)} & \cdots & u_n^{(n-1)} \end{vmatrix}$$

For any n functions, $W(x) = 0$ if some one u_i is linearly dependent on the others, as $u_n = k_1u_1 + k_2u_2 + \cdots + k_{n-1}u_{n-1}$ with the coefficients k_i constant. And for n solutions of a linear differential equation of the nth order, if $W(x) \neq 0$, the solutions are linearly independent.

Constant Coefficients To solve the homogeneous equation of the nth order $A_nd^ny/dx^n + A_{n-1}\,d^{n-1}\,y/dx^{n-1} + \cdots + A_1dy/dx + A_0y = 0$, $A_n \neq 0$, where $A_n, A_{n-1}, \ldots, A_0$ are constants, find the roots of the auxiliary equation

$$A_np^n + A_{n-1}p^{n-1} + \cdots + A_1p + A_0 = 0$$

For each simple real root r, there is a term ce^{rx} in the solution. The terms of the solution are to be added together. When r occurs twice among the n roots of the auxiliary equation, the corresponding term is $e^{rx}(c_1 + c_2x)$. When r occurs three times, the corresponding term is $e^{rx}(c_1 + c_2x + c_3x^2)$, and so forth. When there is a pair of conjugate complex roots $a + bi$ and $a - bi$, the real form of the terms in the solution is $e^{ax}(c_1 \cos bx + d_1 \sin bx)$. When the same pair occurs twice, the corresponding term is $e^{ax}[(c_1 + c_2x) \cos bx + (d_1 + d_2x) \sin bx]$, and so forth.

Consider next the general nonhomogeneous linear differential equation of order n, with constant coefficients, or

$$A_nd^ny/dx^n + A_{n-1}d^{n-1}y/dx^{n-1} + \cdots + A_1dy/dx + A_0y = E(x)$$

We may solve this by adding any particular integral to the complementary function, or general solution, of the homogeneous equation obtained by replacing $E(x)$ by zero. The complementary function may be found from the rules just given. And the particular integral may be found by the methods of the following paragraphs.

Undetermined Coefficients In the last equation, let the right member $E(x)$ be a sum of terms each of which is of the type k, $k \cos bx$, $k \sin bx$, ke^{ax}, kx, or more generally, kx^me^{ax}, $kx^me^{ax} \cos bx$, or $kx^me^{ax} \sin bx$. Here m is zero or a positive integer, and a and b are any real numbers. Then the form of the particular integral I may be predicted by the following rules.

CASE 1. $E(x)$ **is a single term** T. Let D be written for d/dx, so that the given equation is $P(D)y = E(x)$, where $P(D) = A_nD^n + A_{n-1}D^{n-1} + \cdots + A_1D + A_0y$. With the term T associate the simplest polynomial $Q(D)$ such that $Q(D)T = 0$. For the particular types k, etc., $Q(D)$ will be D, $D^2 + b^2$, $D^2 + b^2$, $D - a$, D^2; and for the general types $kx^m\,e^{ax}$, etc., $Q(D)$ will be $(D - a)^{m+1}$, $(D^2 - 2aD + a^2 + b^2)^{m+1}$, $(D^2 - 2aD + a^2 + b^2)^{m+1}$. Thus $Q(D)$ will always be some power of a first- or second-degree factor, $Q(D) = F^v$, $F = D - a$, or $F = D^2 - 2aD + a^2 + b^2$.

Use the method described under **Constant Coefficients** to find the terms in the solution of $P(D)y = 0$ and also the terms in the solution of $Q(D)P(D)y = 0$. Then assume the particular integral I is a linear combination with unknown coefficients of those terms in the solution of $Q(D)P(D)y = 0$ which are not in the solution of $P(D)y = 0$. Thus if $Q(D) = F^q$ and F is *not* a factor of $P(D)$, assume $I = (Ax^{q-1} + Bx^{q-2} + \cdots + L)e^{ax}$ when $F = D - a$, and assume $I = (Ax^{q-1} + Bx^{q-2} + \cdots + L)e^{ax} \cos bx + (Mx^{q-1} + Nx^{q-2} + \cdots + R)e^{ax} \sin bx$ when $F = D^2 - 2aD + a^2 + b^2$. When F is a factor of $P(D)$ and the highest power of F which is a divisor of $P(D)$ is F^k, try the I above multiplied by x^k.

CASE 2. $E(x)$ **is a sum of terms.** With each term in $E(x)$, associate a polynomial $Q(D) = F^q$ as before. Arrange in one group all the terms that have the same F. The particular integral of the given equation will be the sum of solutions of equations each of which has one group on the right. For any one such equation, the form of the particular integral is given as for Case 1, with q the highest power of F associated with any term of the group on the right.

After the form has been found in Case 1 or 2, the unknown coefficients follow when we substitute back in the given differential equation, equate coefficients of like terms, and solve the resulting system of simultaneous equations.

Variation of Parameters. Whenever a fundamental system of solutions $u_1, u_2, \ldots, u_n$ for the homogeneous equation is known, a particular integral of

$$A_n(x)d^ny/dx^n + A_{n-1}(x)d^{n-1}y/dx^{n-1} + \cdots + A_1(x)dy/dx + A_0(x)y = E(x)$$

may be found in the form $y = \Sigma v_ku_k$. In this and the next few summations, k runs from 1 to n. The v_k are functions of x, found by integrating their derivatives v_k', and these derivatives are the solutions of the n simultaneous equations $\Sigma v_k'u_k = 0, \Sigma v_k'u_k' = 0, \Sigma v_k'u''_k = 0, \cdots, \Sigma v_k'u_k^{(n-2)} = 0, A_n(x)\Sigma v_k'u_k^{(n-1)} = E(x)$. To find the v_k from $v_k = \int v_k'\,dx + c_k$, any choice of constants will lead to a particular integral. The special choice $v_k = \int_0^x v_k'\,dx$ leads to the particular integral having $y, y', y'', \ldots, y^{(n-1)}$ each equal to zero when $x = 0$.

The Cauchy-Euler Equidimensional Equation This has the form

$$k_nx^nd^ny/dx^n + k_{n-1}x^{n-1}d^{n-1}y/dx^{n-1} + \cdots + k_1x\,dy/dx + k_0y = F(x)$$

The substitution $x = e^t$, which makes

$$x\,dy/dx = dy/dt$$
$$x^kd^ky/dx^k = (d/dt - k + 1) \cdots (d/dt - 2)(d/dt - 1)\,dy/dt$$

transforms this into a linear differential equation with constant coefficients. Its solution $y = g(t)$ leads to $y = g(\ln x)$ as the solution of the given Cauchy-Euler equation.

Bessel's Equation The general Bessel equation of order n is:

$$x^2y'' + xy' + (x^2 - n^2)y = 0$$

This equation has general solution

$$y = AJ_n(x) + BJ_{-n}(x)$$

when n is not an integer. Here, $J_n(x)$ and $J_{-n}(x)$ are Bessel functions (see section on Special Functions).

In case $n = 0$, Bessel's equation has solution

$$y = AJ_0(x) + B\left[J_0(x) \ln(x) - \sum_{k=1}^{\infty} \frac{(-1)^kH_kx^{2k}}{2^{2k}(k!)^2}\right]$$

where H_k is the kth partial sum of the harmonic series, $1 + \frac{1}{2} + \frac{1}{3} + \cdots + 1/k$.

In case $n = 1$, the solution is

$$y = AJ_1(x) + B\left\{J_1(x) \ln(x) + 1/x - \left[\sum_{k=1}^{\infty} \frac{(-1)^k(H_k + H_{k-1})x^{2k-1}}{2^{2k}k!(k-1)!}\right]\right\}$$

In case $n > 1$, n is an integer, solution is

$$y = AJ_n(x) + B\left\{J_n(x) \ln(x) + \left[\sum_{k=0}^{\infty} \frac{(-1)^{k+1}(n-1)!x^{2k-n}}{2^{2k+1-n}k!(1-n)^k}\right] + \tfrac{1}{2}\left[\sum_{k=0}^{\infty} \frac{(-1)^{k+1}(H_k + H_{k+1})x^{2k+n}}{2^{2k+n}k!(k+n)!}\right]\right\}$$

Solutions to Bessel's equation may be given in several other forms, often exploiting the relation between H_k and $\ln(k)$ or the so-called *Euler constant.*

General Method of Power Series Given a general differential equation $F(x, y, y', \ldots) = 0$, the solution may be expanded as a Maclaurin series, so $y = \Sigma_{n=0}^{\infty}a_nx^n$, where $a_n = f^{(n)}(0)/n!$. The power

series for y may be differentiated formally, so that $y' = \sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n$, and $y'' = \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \sum_{n=0}^{\infty} (n+1)(n+2) a_{n+2} x^n$.

Substituting these series into the equation $F(x, y, y', \ldots) = 0$ often gives useful recursive relationships, giving the value of a_n in terms of previous values. If approximate solutions are useful, then it may be sufficient to take the first few terms of the Maclaurin series as a solution to the equation.

EXAMPLE. Consider $y'' - y' + xy = 0$. The procedure gives $\sum_{n=0}^{\infty} (n+1)(n+2) a_{n+2} x^n - \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n + x \sum_{n=0}^{\infty} a_n x^n = \sum_{n=0}^{\infty} (n+1)(n+2) a_{n+2} x^n - \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n + \sum_{n=1}^{\infty} a_{n-1} x^n = (2a_2 - a_1) x^0 + \sum_{n=1}^{\infty} [(n+1)(n+2) a_{n+2} - (n+1) a_{n+1} + a_{n-1}] x^n = 0$. Thus $2a_2 - a_1 = 0$ and, for $n > 0$, $(n+1)(n+2) a_{n+2} - (n+1) a_{n+1} + a_{n-1} = 0$. Thus, a_0 and a_1 may be determined arbitrarily, but thereafter, the values of a_n are determined recursively.

PARTIAL DIFFERENTIAL EQUATIONS

Partial differential equations (PDEs) arise when there are two or more independent variables. Two notations are common for the partial derivatives involved in PDEs, the "del" or fraction notation, where the first partial derivative of f with respect to x would be written $\partial f / \partial x$, and the subscript notation, where it would be written f_x.

In the same way that ordinary differential equations often involve arbitrary constants, solutions to PDEs often involve arbitrary functions.

EXAMPLE. $f_{xy} = 0$ has as its general solution $g(x) + h(y)$. The function g does not depend on y, so $g_y = 0$. Similarly, $f_x = 0$.

PDEs usually involve boundary or initial conditions dictated by the application. These are analogous to initial conditions in ordinary differential equations.

In solving PDEs, it is seldom feasible to find a general solution and then specialize that general solution to satisfy the boundary conditions, as is done with ordinary differential equations. Instead, the boundary conditions usually play a key role in the solution of a problem. A notable exception to this is the case of linear, homogeneous PDEs since they have the property that if f_1 and f_2 are solutions, then $f_1 + f_2$ is also a solution. The wave equation is one such equation, and this property is the key to the solution described in the section "Fourier Series."

Often it is difficult to find exact solutions to PDEs, so it is necessary to resort to approximations or numerical solutions. (See also "Numerical Methods" below.)

Classification of PDEs

Linear A PDE is **linear** if it involves only first derivatives, and then only to the first power. The general form of a linear PDE, in two independent variables, x and y, and the dependent variable z, is $P(x, y, z) f_x + Q(x, y, z) f_y = R(x, y, z)$, and it will have a solution of the form $z = f(x, y)$ if its solution is a function, or $F(x, y, z) = 0$ if the solution is not a function.

Elliptic Laplace's equation $f_{xx} + f_{yy} = 0$ and Poisson's equation $f_{xx} + f_{yy} = g(x, y)$ are the prototypical elliptic equations. They have analogs in more than two variables. They do not explicitly involve the variable time and generally describe steady-state or equilibrium conditions, gravitational potential, where boundary conditions are distributions of mass, electrical potential, where boundary conditions are electrical charges, or equilibrium temperatures, and where boundary conditions are points where the temperature is held constant.

Parabolic $T_t = T_{xx} + T_{yy}$ represents the dynamic condition of diffusion or heat conduction, where $T(x, y, t)$ usually represents the temperature at time t at the point (x, y). Note that when the system reaches steady state, the temperature is no longer changing, so $T_t = 0$, and this becomes Laplace's equation.

Hyperbolic Wave propagation is described by equations of the type $u_{tt} = c^2(u_{xx} + u_{yy})$, where c is the velocity of waves in the medium.

VECTOR CALCULUS

Vector Fields A **vector field** is a function that assigns a vector to each point in a region. If the region is two-dimensional, then the vectors assigned are two-dimensional, and the vector field is a two-dimensional vector field, denoted $\mathbf{F}(x, y)$. In the same way, a three-dimensional vector field is denoted $\mathbf{F}(x, y, z)$.

A three-dimensional vector field can always be written:

$$\mathbf{F}(x, y, z) = f_1(x, y, z)\mathbf{i} + f_2(x, y, z)\mathbf{j} + f_3(x, y, z)\mathbf{k}$$

where **i, j,** and **k** are the basis vectors (1, 0, 0), (0, 1, 0), and (0, 0, 1), respectively. The functions f_1, f_2, and f_3 are called **coordinate functions** of **F**.

Gradient If $f(x, y)$ is a function of two variables, then the **gradient** is the associated vector field $\text{grad}(f) = f_x\mathbf{i} + f_y\mathbf{j}$. Similarly, the gradient of a function of three variables is $f_x\mathbf{i} + f_y\mathbf{j} + f_z\mathbf{k}$. At any point, the direction of the gradient vector points in the direction in which the function is increasing most rapidly, and the magnitude is the rate of increase in that direction.

Parameterized Curves If C is a curve from a point A to a point B, either in two dimensions or in three dimensions, then a **parameterization** of C is a vector-valued function $\mathbf{r}(t) = r_1(t)\mathbf{i} + r_2(t)\mathbf{j} + r_3(t)\mathbf{k}$, which satisfies $\mathbf{r}(a) = A$, $\mathbf{r}(b) = B$, and $\mathbf{r}(t)$ is on the curve C, for $a \le t \le b$. It is also necessary that the function $\mathbf{r}(t)$ be continuous and one-to-one. A given curve C has many different parameterizations.

The derivative of a parameterization $\mathbf{r}(t)$ is a vector-valued function $\mathbf{r}'(t) = r_1'(t)\mathbf{i} + r_2'(t)\mathbf{j} + r_3'(t)\mathbf{k}$. The derivative is the velocity function of the parameterization. It is always tangent to the curve C, and the magnitude is the speed of the parameterization.

Line Integrals If **F** is a vector field, C is a curve, and $\mathbf{r}(t)$ is a parameterization of C, then the **line integral,** or **work integral,** of **F** along C is

$$W = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_a^b \mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t)\, dt$$

This is sometimes called the work integral because if **F** is a force field, then W is the amount of work necessary to move an object along the curve C from A to B.

Divergence and Curl The **divergence** of a vector field **F** is $\text{div } \mathbf{F} = f_{1x} + f_{2y} + f_{3z}$. If **F** represents the flow of a fluid, then the divergence at a point represents the rate at which the fluid is expanding at that point. Vector fields with $\text{div } \mathbf{F} = 0$ are called **incompressible.**

The **curl** of **F** is

$$\text{curl } \mathbf{F} = (f_{3y} - f_{2z})\mathbf{i} + (f_{1z} - f_{3x})\mathbf{j} + (f_{2x} - f_{1y})\mathbf{k}$$

If **F** is a two-dimensional vector field, then the first two terms of the curl are zero, so the curl is just

$$\text{curl } \mathbf{F} = (f_{2x} - f_{1y})\mathbf{k}$$

If **F** represents the flow of a fluid, then the curl represents the rotation of the fluid at a given point. Vector fields with $\text{curl } \mathbf{F} = \mathbf{0}$ are called **irrotational.**

Two important facts relate div, grad, and curl:

1. $\text{div}(\text{curl } \mathbf{F}) = 0$
2. $\text{curl}(\text{grad } f) = \mathbf{0}$

Conservative Vector Fields A vector field $\mathbf{F} = f_1\mathbf{i} + f_2\,\mathbf{j} + f_3\mathbf{k}$ is **conservative** if all of the following are satisfied:

$$f_{1y} = f_{2x} \qquad f_{1z} = f_{3x} \qquad \text{and} \qquad f_{2z} = f_{3y}$$

If **F** is a two-dimensional vector field, then the second and third conditions are always satisfied, and so only the first condition must be checked. Conservative vector fields have three important properties:

1. $\int_C \mathbf{F} \cdot d\mathbf{r}$ has the same value regardless of what curve C is chosen that connects the points A and B. This property is called **path independence.**
2. **F** is the gradient of some function $f(x, y, z)$.
3. $\text{Curl } \mathbf{F} = \mathbf{0}$.

In the special case that $\mathbf{F}$ is a conservative vector field, if $\mathbf{F} = \text{grad}\,(f)$, then

$$\int_C \mathbf{F} \cdot d\mathbf{r} = f(B) - f(A)$$

THEOREMS ABOUT LINE AND SURFACE INTEGRALS

Two important theorems relate line integrals with double integrals. If R is a region in the plane and if C is the curve tracing the boundary of R in the positive (counterclockwise) direction, and if $\mathbf{F}$ is a continuous vector field with continuous first partial derivatives, line integrals on C are related to double integrals on R by Green's theorem and the divergence theorem.

Green's Theorem

$$\int_C \mathbf{F} \cdot d\mathbf{r} = \iint_R \text{curl}\,(\mathbf{F}) \cdot d\mathbf{S}$$

The right-hand double integral may also be written as $\iint_R |\text{curl}\,(\mathbf{F})|\,dA$.

Green's theorem describes the total rotation of a vector field in two different ways, on the left in terms of the boundary of the region and on the right in terms of the rotation at each point within the region.

Divergence Theorem

$$\int_C \mathbf{F} \cdot d\mathbf{N} = \iint_R \text{div}\,(\mathbf{F})\,dA$$

where $\mathbf{N}$ is the so-called *normal vector field* to the curve C. The divergence theorem describes the expansion of a region in two distinct ways, on the left in terms of the flux across the boundary of the region and on the right in terms of the expansion at each point within the region.

Both Green's theorem and the divergence theorem have corresponding theorems involving surface integrals and volume integrals in three dimensions.

LAPLACE AND FOURIER TRANSFORMS

Laplace Transforms The Laplace transform is used to convert equations involving a time variable t into equations involving a frequency variable s. There are essentially three reasons for doing this: (1) higher-order differential equations may be converted to purely algebraic equations, which are more easily solved; (2) boundary conditions are easily handled; and (3) the method is well-suited to the theory associated with the **Nyquist stability criteria.**

In Laplace-transformation mathematics the following symbols and equations are used (Tables 2.1.4 and 2.1.5):

$f(t)$ = a function of time
s = a complex variable of the form $(\sigma + j\omega)$
$F(s)$ = an equation expressed in the transform variable s, resulting from operating on a function of time with the Laplace integral
$\mathcal{L}$ = an operational symbol indicating that the quantity which it prefixes is to be transformed into the frequency domain
$f(0^+)$ = the limit from the positive direction of $f(t)$ as t approaches zero
$f(0^-)$ = the limit from the negative direction of $f(t)$ as t approaches zero

Therefore, $F(s) = \mathcal{L}[f(t)]$. The Laplace integral is defined as

$$\mathcal{L} = \int_0^\infty e^{-st}\,dt. \text{ Therefore, } \mathcal{L}[f(t)] = \int_0^\infty e^{-st} f(t)\,dt$$

Table 2.1.4 Laplace Transforms

$f(t)$	$F(s) = \mathcal{L}(f(t))$	Name of function
1. a	a/s	
2. 1	$1/s$	
3. $u_a(t) = \begin{cases} 0 & t < a \\ 1 & t > a \end{cases}$	e^{-as}/S	Heavyside or step function
4. $\delta_a(t) = u_a'(t)$	e^{-as}	Dirac or impulse function
5. e^{at}	$1/(s - a)$	
6. $(1/r)e^{-t/r}$	$1/(rs + 1)$	
7. ke^{-at}	$k/(s + a)$	
8. $\sin at$	$a/(s^2 + a^2)$	
9. $\cos at$	$s/(s^2 + a^2)$	
10. $e^{-at}\sin bt$	$b/[(s + a)^2 + b^2]$	
11. $\dfrac{e^{at}}{a - b} - \dfrac{e^{bt}}{a - b}$	$\dfrac{1}{(s - a)(s - b)}$	
12. t	$1/s^2$	
13. t^2	$2/s^3$	
14. t^n	$n!/s^{n+1}$	
15. t^a	$\Gamma(a + 1)/s^{a+1}$	Gamma function (see "Special Functions")
16. $\sinh at$	$a/(s^2 - a^2)$	
17. $\cosh at$	$s/(s^2 - a^2)$	
18. $t^n e^{at}$	$n!/(s - a)^{n+1}$	
19. $t\cos at$	$(s^2 - a^2)/(s^2 + a^2)^2$	
20. $t\sin at$	$2as/(s^2 + a^2)^2$	
21. $\sin at - at\cos at$	$2a^3/(s^2 + a^2)^2$	
22. $\arctan a/s$	$(\sin at)/t$	

Table 2.1.5 Properties of Laplace Transforms

$f(t)$	$F(s) = \mathcal{L}(f(t))$	Name of rule
1. $f(t)$	$\int_0^\infty e^{-st} f(t)\,dt$	Definition
2. $f(t) + g(t)$	$F(s) + G(s)$	Addition
3. $kf(t)$	$kF(s)$	Scalar multiples
4. $f'(t)$	$sF(s) - f(0^+)$	Derivative laws
5. $f''(t)$	$s^2F(s) - sf(0^+) - f'(0^+)$	
6. $f'''(t)$	$s^3F(s) - s^2f(0^+) - sf'(0^+) - f''(0^+)$	
7. $\int f(t)\,dt$	$(1/s)F(s) + (1/s)\int f(t)\,dt\|_{0^+}$	Integral law
8. $f(bt)$	$(1/b)F(s/b)$	Change of scale
9. $e^{at}f(t)$	$F(s - a)$	First shifting
10. $f * g(t)$	$F(s)G(s)$	Convolution
11. $u_a(t)f(t - a)$	$F(s)e^{-at}$	Second shifting
12. $-tf(t)$	$F'(s)$	Derivative in s

Direct Transforms

EXAMPLE.

$$f(t) = \sin \beta t$$

$$\mathcal{L}[f(t)] = \mathcal{L}(\sin \beta t) = \int_0^\infty \sin \beta t\, e^{-st}\,dt$$

but $$\sin \beta t = \frac{e^{j\beta t} - e^{-j\beta t}}{2j} \quad \text{where} \quad j^2 = -1$$

$$\mathcal{L}(\sin \beta t) = \frac{1}{2j}\int_0^\infty (e^{j\beta t} - e^{-j\beta t})e^{-st}\,dt$$

$$= \frac{1}{2j}\left(\frac{-1}{s - j\beta}\right) e^{(-s+j\beta)t}\Big|_0^\infty - \frac{1}{2j}\left(\frac{-1}{s + j\beta}\right) e^{(-s-j\beta)t}\Big|_0^\infty$$

$$= \frac{\beta}{s^2 + \beta^2}$$

Table 2.1.4 lists the transforms of common time-variable expressions.

Some special functions are frequently encountered when using Laplace methods.

The **Heavyside,** or **step, function** $u_a(t)$ sometimes written $u(t - a)$, is zero for all $t < a$ and 1 for all $t > a$. Its value at $t = a$ is defined differently in different applications, as 0, ½, or 1, or it is simply left undefined. In Laplace applications, the value of a function at a single point does not matter. The Heavyside function describes a force which is "off" until time $t = a$ and then instantly goes "on."

The **Dirac delta function,** or **impulse function,** $\delta_a(t)$, sometimes written $\delta(t - a)$, is the derivative of the Heavyside function. Its value is always zero, except at $t = a$, where its value is "positive infinity." It is sometimes described as a "point mass function." The delta function describes an impulse or an instantaneous transfer of momentum.

The derivative of the Dirac delta function is called the **dipole function.** It is less frequently encountered.

The **convolution** $f * g(t)$ of two functions $f(t)$ and $g(t)$ is defined as

$$f * g(t) = \int_0^t f(u)g(t - u)\,du$$

Laplace transforms are often used to solve differential equations arising from so-called *linear systems.* Many vibrating systems and electrical circuits are linear systems. If an input function $f_i(t)$ describes the forces exerted upon a system and a response or output function $f_o(t)$ describes the motion of the system, then the **transfer function** $T(s) = F_o(s)/F_i(s)$. Linear systems have the special property that the transfer function is independent of the input function, within the elastic limits of the system. Therefore,

$$\frac{F_o(s)}{F_i(s)} = \frac{G_o(s)}{G_i(s)}$$

This gives a technique for describing the response of a system to a complicated input function if its response to a simple input function is known.

EXAMPLE. Solve $y'' + 2y' - 3y = 8e^t$ subject to initial conditions $y(0) = 2$ and $y'(0) = 0$. Let $y = f(t)$ and $Y = F(s)$. Take Laplace transforms of both sides and substitute for $y(0)$ and $y'(0)$, and get

$$s^2Y - 2s + 2(sY - 2) - 3Y = \frac{8}{s - 1}$$

Solve for Y, apply partial fractions, and get

$$\begin{aligned} Y &= \frac{2s^2 + 2s + 4}{(s + 3)(s - 1)^2} \\ &= \frac{1}{s + 3} + \frac{s + 1}{(s - 1)^2} \\ &= \frac{1}{(s + 3)} + \frac{1}{(s - 1)} + \frac{2}{(s - 1)^2} \end{aligned}$$

Using the tables of transforms to find what function has Y as its transform, we get

$$y = e^{-3t} + e^t + 2te^t$$

EXAMPLE. A vibrating system responds to an input function $f_i(t) = \sin t$ with a response $f_o(t) = \sin 2t$. Find the system response to the input $g_i(t) = \sin 2t$.

Apply the invariance of the transfer function, and get

$$\begin{aligned} G_o(s) &= \frac{F_oG_i}{F_i} \\ &= \frac{4(s^2 + 1)}{(s^2 + 4)^2} \\ &= \frac{2(2)}{s^2 + 2^2} - \frac{12}{16}\left[\frac{16}{(s^2 + 2^2)^2}\right] \end{aligned}$$

Applying formulas 8 and 21 from Table 2.1.4 of Laplace transforms,

$$g_o(t) = 2 \sin 2t - ¾ \sin 2t + ½\, t \cos 2t$$

Inversion When an equation has been transformed, an explicit solution for the unknown may be directly determined through algebraic manipulation. In automatic-control design, the equation is usually the differential equation describing the system, and the unknown is either the output quantity or the error. The solution gained from the transformed equation is expressed in terms of the complex variable s. For many design or analysis purposes, the solution in s is sufficient, but in some cases it is necessary to retransform the solution in terms of time. The process of passing from the complex-variable (frequency domain) expression to that of time (time domain) is called an **inverse transformation.** It is represented symbolically as

$$\mathcal{L}^{-1}F(s) = f(t)$$

For any $f(t)$ there is only one direct transform, $F(s)$. For any given $F(s)$ there is only one inverse transform $f(t)$. Therefore, tables are generally used for determining inverse transforms. Very complete tables of inverse transforms may be found in Gardner and Barnes, "Transients in Linear Systems." As an example of the inverse procedure consider an equation of the form

$$K = \alpha x(t) + \int \frac{x(t)}{\beta}\,dt$$

It is desired to obtain an expression for $x(t)$ resulting from an instantaneous change in the quantity K. Transforming the last equation yields

$$\frac{K}{s} = X(s)\alpha + \frac{X(s)}{s\beta} + \frac{f^{-1}(0^+)}{s}$$

If $f^{-1}(0)/s = 0$

then

$$X(s) = \frac{K/\alpha}{s + 1/\alpha\beta}$$

$$x(t) = \mathcal{L}^{-1}[X(s)] = \mathcal{L}^{-1}\frac{K/\alpha}{s + 1/\alpha\beta}$$

From Table 2.1.4, $x(t) = \dfrac{K}{\alpha}e^{-t/\alpha\beta}$

Fourier Coefficients Fourier coefficients are used to analyze periodic functions in terms of sines and cosines. If $f(x)$ is a function with period $2L$, then the Fourier coefficients are defined as

$$a_n = \frac{1}{L}\int_{-L}^{L} f(s)\cos\frac{n\pi s}{L}\,ds \qquad n = 0, 1, 2, \ldots$$

$$b_n = \frac{1}{L}\int_{-L}^{L} f(s)\sin\frac{n\pi s}{L}\,ds \qquad n = 1, 2, \ldots$$

Equivalently, the bounds of integration may be taken as 0 to $2L$ instead of $-L$ to L. Many treatments take $L = \pi$ or $L = 1$.

Then the Fourier theorem states that

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos\left(\frac{n\pi x}{L}\right) + b_n \sin\left(\frac{n\pi x}{L}\right)$$

The series on the right is called the "Fourier series of the function $f(x)$." The convergence of the Fourier series is usually rapid, so that the function $f(x)$ is usually well-approximated by the sum of the first few sums of the series.

Examples of the Fourier Series If $y = f(x)$ is the curve in Figs. 2.1.110 to 2.1.112, then in Fig. 2.1.110,

$$y = \frac{h}{2} - \frac{4h}{\pi^2}\left(\cos\frac{\pi x}{c} + \frac{1}{9}\cos\frac{3\pi x}{c} + \frac{1}{25}\cos\frac{5\pi x}{c} + \cdots\right)$$

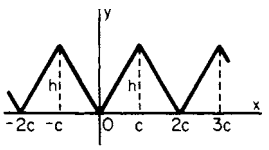

Fig. 2.1.110 Saw-tooth curve.

In Fig. 2.1.111,

$$y = \frac{4h}{\pi}\left(\sin\frac{\pi x}{c} + \frac{1}{3}\sin\frac{3\pi x}{c} + \frac{1}{5}\sin\frac{5\pi x}{c} + \cdots\right)$$

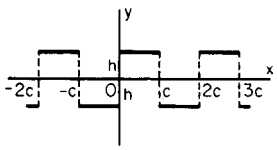

Fig. 2.1.111 Step-function curve or square wave.

In Fig. 2.1.112,

$$y = \frac{2h}{\pi}\left(\sin\frac{\pi x}{c} - \frac{1}{2}\sin\frac{2\pi x}{c} + \frac{1}{3}\sin\frac{3\pi x}{c} - \cdots\right)$$

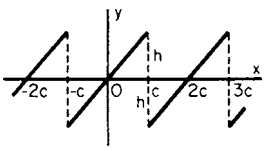

Fig. 2.1.112 Linear-sweep curve.

If the Fourier coefficients of a function $f(x)$ are known, then the coefficients of the derivative $f'(x)$ can be found, when they exist, as follows:

$$a'_n = nb_n \qquad b'_n = -na_n$$

where a'_n and b'_n are the Fourier coefficients of $f'(x)$.

The **complex Fourier coefficients** are defined by:

$$c_n = \tfrac{1}{2}(a_n - ib_n)$$
$$c_0 = \tfrac{1}{2}a_0$$
$$c_n = \tfrac{1}{2}(a_n + ib_n)$$

Then the complex form of the Fourier theorem is

$$f(x) = \sum_{n=-\infty}^{\infty} c_n e^{in\pi x/L}$$

Wave Equation Fourier series are often used in the solution of the wave equation $a^2u_{xx} = u_{tt}$ where $0 < x < L$, $t > 0$, and initial conditions are $u(x, 0) = f(x)$ and $u_t(x, 0) = g(x)$. This describes the position of a vibrating string of length L, fixed at both ends, with initial position $f(x)$ and initial velocity $g(x)$. The constant a is the velocity at which waves are propagated along the string, and is given by $a^2 = T/p$, where T is the tension in the string and p is the mass per unit length of the string.

If $f(x)$ is extended to the interval $-L < x < L$ by setting $f(-x) = -f(x)$, then f may be considered periodic of period $2L$. Its Fourier coefficients are

$$a_n = 0 \qquad b_n = \int_{-L}^{L} f(x)\sin\frac{n\pi x}{L}\pi\,dx \qquad n = 1, 2, \ldots$$

The solution to the wave equation is

$$u(x, t) = \sum_{n=1}^{\infty} b_n \sin\frac{n\pi x}{L}\cos\frac{n\pi t}{L}$$

Fourier transform A nonperiodic function $f(x)$ requires two functions to describe its Fourier transform:

$$A(w) = \int_{-\infty}^{\infty} f(x)\cos wx\,dx$$

$$B(w) = \int_{-\infty}^{\infty} f(x)\sin wx\,dx$$

Then the **Fourier integral equation** is

$$f(x) = \int_0^{\infty} A(w)\cos wx + B(w)\sin wx\,dw$$

The **complex Fourier transform** of $f(x)$ is defined as

$$F(w) = \int_{-\infty}^{\infty} f(x)\,e^{iwx}\,dx$$

Then the **complex Fourier integral equation** is

$$f(x) = \frac{1}{2\pi}\int_0^{\infty} F(w)e^{-iwx}\,dx$$

Heat Equation The Fourier transform may be used to solve the one-dimensional heat equation $u_t(x, t) = u_{xx}(x, t)$, for $t > 0$, given initial condition $u(x, 0) = f(x)$. Let $F(s)$ be the complex Fourier transform of $f(x)$, and let $U(s, t)$ be the complex Fourier transform of $u(x, t)$. Then the transform of $u_t(x, t)$ is $dU(s, t)/dt$.

Transforming $u_t(x, t) = u_{xx}(s, t)$ yields $dU/dt + s^2U = 0$ and $U(s, 0) = f(s)$. Solving this using the Laplace transform gives $U(s, t) = F(s)e^{s^2t}$.

Applying the complex Fourier integral equation, which gives $u(x, t)$ in terms of $U(s, t)$, gives

$$u(x, t) = \frac{1}{2\pi}\int_0^{\infty} U(s, t)e^{-isx}\,ds$$
$$= \frac{1}{2\pi}\int_{-\infty}^{\infty}\int_0^{\infty} f(y)e^{is(y-x)}e^{s^2t}\,ds\,dy$$

Applying the Euler formula, $e^{ix} = \cos x + i\sin x$,

$$u(x, t) = \frac{1}{2\pi}\int_{-\infty}^{\infty}\int_0^{\infty} f(y)\cos\,(s(y - x))e^{s^2t}\,ds\,dy$$

SPECIAL FUNCTIONS

Gamma Function The gamma function is a generalization of the factorial function. It arises in Laplace transforms of polynomials, in continuous probability, applications involving fractals and fractional derivatives, and in the solution to certain differential equations. It is defined by the improper integral:

$$\Gamma(x) = \int_0^{\infty} t^{x-1}e^{-t}\,dt$$

The integral converges for $x > 0$ and diverges otherwise. The function is extended to all negative values, except negative integers, by the relation

$$\Gamma(x + 1) = x\Gamma(x)$$

The gamma function is related to the factorial function by

$$\Gamma(n + 1) = n!$$

for all positive integers n.

An important value of the gamma function is

$$\Gamma(0.5) = \pi^{1/2}$$

Other values of the gamma function are found in CRC Standard Mathematical Tables and similar tables.

Beta Function The beta function is a function of two variables and is a generalization of the binomial coefficients. It is closely related to

the gamma function. It is defined by the integral:

$$B(x, y) = \int_0^1 t^{x-1}(1 - t)^{y-1}\,dt \qquad \text{for } x, y > 0$$

The beta function can also be represented as a trigonometric integral, by substituting $t = \sin^2 \theta$, as

$$B(x, y) = 2\int_0^{\pi/2} (\sin\theta)^{2x-1}(\cos\theta)^{2y-1}\,d\theta$$

The beta function is related to the gamma function by the relation

$$B(x, y) = \frac{\Gamma(x)\Gamma(y)}{\Gamma(x + y)}$$

This relation shows that $B(x, y) = B(y, x)$.

Bernoulli Functions The Bernoulli functions are a sequence of periodic functions of period 1 used in approximation theory. Note that for any number x, $[x]$ represents the largest integer less than or equal to x. $[3.14] = 3$ and $[-1.2] = -2$. The Bernoulli functions $B_n(x)$ are defined recursively as follows:

1. $B_0(x) = 1$
2. $B_1(x) = x - [x] - \frac{1}{2}$
3. B_{n+1} is defined so that $B'_{n+1}(x) = B_n(x)$ and so that B_{n+1} is periodic of period 1.

B_1 is a special case of the linear-sweep curve (Fig. 2.1.112).

Bessel Functions of the First Kind Bessel functions of the first kind arise in the solution of Bessel's equation of order v:

$$x^2y'' + xy' + (x^2 - v^2)y = 0$$

When this is solved using series methods, the recursive relations define the Bessel functions of the first kind of order v:

$$J_v(x) = \sum_{k=0}^{\infty} \frac{(-1)^k}{k!(v + k + 1)}\left(\frac{x}{2}\right)^{v+2k}$$

Chebyshev Polynomials The Chebyshev polynomials arise in the solution of PDEs of the form

$$(1 - x^2)y'' - xy' + n^2y = 0$$

and in approximation theory. They are defined as follows:

$$T_0(x) = 1 \qquad T_2(x) = 2x^2 - 1$$
$$T_1(x) = x \qquad T_3(x) = 4x^3 - 3x$$

For $n > 3$, they are defined recursively by the relation

$$T_{n+1}(x) - 2xT_n(x) + T_{n-1}(x) = 0$$

Chebyshev polynomials are said to be orthogonal because they have the property

$$\int_{-1}^{1} \frac{T_n(x)T_m(x)}{(1 - x^2)^{1/2}}\,dx = 0 \qquad \text{for } n \neq m$$

NUMERICAL METHODS

Introduction Classical numerical analysis is based on polynomial approximation of the infinite operations of integration, differentiation, and interpolation. The objective of such analyses is to replace difficult or impossible exact computations with easier approximate computations. The challenge is to make the approximate computations short enough and accurate enough to be useful.

Modern numerical analysis includes Fourier methods, including the *f*ast *F*ourier *t*ransform (FFT) and many problems involving the way computers perform calculations. Modern aspects of the theory are changing very rapidly.

Errors Actual value = calculated value + error. There are several sources of errors in a calculation: mistakes, round-off errors, truncation errors, and accumulation errors.

Round-off errors arise from the use of a number not sufficiently accurate to represent the actual value of the number, for example, using 3.14159 to represent the irrational number π, or using 0.56 to represent $\frac{9}{16}$ or 0.5625.

Truncation errors arise when a finite number of steps are used to approximate an infinite number of steps, for example, the first n terms of a series are used instead of the infinite series.

Accumulation errors occur when an error in one step is carried forward into another step. For example, if $x = 0.994$ has been previously rounded to 0.99, then $1 - x$ will be calculated as 0.01, while its true value is 0.006. An error of less than 1 percent is accumulated into an error of over 50 percent in just one step. Accumulation errors are particularly characteristic of methods involving recursion or iteration, where the same step is performed many times, with the results of one iteration used as the input for the next.

Simultaneous Linear Equations The matrix equation $Ax = b$ can be solved directly by finding A^{-1}, or it can be solved iteratively, by the method of **iteration in total steps:**

1. If necessary, rearrange the rows of the equation so that there are no zeros on the diagonal of A.
2. Take as initial approximations for the values of x_i:

$$x_1^{(0)} = \frac{b_1}{a_{11}} \qquad x_2^{(0)} = \frac{b_2}{a_{22}} \qquad \cdots \qquad x_n^{(0)} = \frac{b_n}{a_{nn}}$$

3. For successive approximations, take

$$x_i^{(k+1)} = (b_i - a_{i1}x_1^{(k)} - \cdots - a_{in}x_n^{(k)})/a_{ii}$$

Repeat step 3 until successive approximations for the values of x_i reach the specified tolerance.

A property of iteration by total steps is that it is self-correcting: that is, it can recover both from mistakes and from accumulation errors.

Zeros of Functions An iterative procedure for solving an equation $f(x) = 0$ is the **Newton-Raphson method.** The algorithm is as follows:

1. Choose a first estimate of a root x_0.
2. Let $x_{k+1} = x_k - f(x_k)/f'(x_k)$. Repeat step 2 until the estimate x_k converges to a root r.
3. If there are other roots of $f(x)$, then let $g(x) = f(x)/(x - r)$ and seek roots of $g(x)$.

False Position If two values x_0 and x_1 are known, such that $f(x_0)$ and $f(x_1)$ are opposite signs, then an iterative procedure for finding a root between x_0 and x_1 is the method of false position.

1. Let $m = [f(x_1) - f(x_0)]/(x_1 - x_0)$.
2. Let $x_2 = x_1 - f(x_1)/m$.
3. Find $f(x_2)$.
4. If $f(x_2)$ and $f(x_1)$ have the same sign, then let $x_1 = x_2$. Otherwise, let $x_0 = x_2$.
5. If x_1 is not a good enough estimate of the root, then return to step 1.

Functional Equatities To solve an equation of the form $f(x) = g(x)$, use the methods above to find roots of the equation $f(x) - g(x) = 0$.

Maxima One method for finding the maximum of a function $f(x)$ on an interval $[a, b]$ is to find the roots of the derivative $f'(x)$. The maximum of $f(x)$ occurs at a root or at an endpoint a or b.

Fibonacci Search An iterative procedure for searching for maxima works if $f(x)$ is unimodular on $[a, b]$. That is, f has only one maximum, and no other local maxima, between a and b. This procedure takes advantage of the so-called *golden ratio*, $r = 0.618034 = (\sqrt{5} - 1)/2$, which arises from the Fibonacci sequence.

1. If a is a sufficiently good estimate of the maximum, then stop. Otherwise, proceed to step 2.
2. Let $x_1 = ra + (1 - r)b$, and let $x_2 = (1 - r)a + rb$. Note $x_1 < x_2$. Find $f(x_1)$ and $f(x_2)$.
   a. If $f(x_1) = f(x_2)$, then let $a = x_1$ and $b = x_2$, and go to step 1.
   b. If $f(x_1) < f(x_2)$, then let $a = x_1$, and go to step 1.
   c. If $f(x_1) > f(x_2)$, then let $b = x_2$, and return to step 1.

In cases b and c, computation is saved since the new value of one of x_1 and x_2 will have been used in the previous step. It has been proved that the Fibonacci search is the fastest possible of the general "cutting" type of searches.

Steepest Ascent If $z = f(x, y)$ is to be maximized, then the method of steepest ascent takes advantage of the fact that the gradient, grad (f) always points in the direction that f is increasing the fastest.

1. Let (x_0, y_0) be an initial guess of the maximum of f.
2. Let e be an initial step size, usually taken to be small.
3. Let $(x_{k+1}, y_{k+1}) = (x_k, y_k) + e \text{ grad } f(x_k, y_k)/|\text{grad } f(x_k, y_k)|$.
4. If $f(x_{k+1}, y_{k+1})$ is not greater than $f(x_k, y_k)$, then replace e with $e/2$ (cut the step size in half) and reperform step 3.
5. If (x_k, y_k) is a sufficiently accurate estimate of the maximum, then stop. Otherwise, repeat step 3.

Minimization The theory of minimization exactly parallels the theory of maximization, since minimizing $z = f(x)$ occurs at the same value of x as maximizing $w = -f(x)$.

Numerical Differentiation In general, numerical differentiation should be avoided where possible, since differentiation tends to be very sensitive to small errors in the value of the function $f(x)$. There are several approximations to $f'(x)$, involving a "step size" h usually taken to be small:

$$f'(x) = \frac{f(x + h) - f(x)}{h}$$

$$f'(x) = \frac{f(x + h) - f(x - h)}{2h}$$

$$f'(x) = \frac{f(x + 2h) + f(x + h) - f(x - h) - f(x - 2h)}{6h}$$

Other formulas are possible.

If a derivative is to be calculated from an equally spaced sequence of measured data, $y_1, y_2, \ldots, y_n$, then the above formulas may be adapted by taking $y_i = f(x_i)$. Then $h = x_{i+1} - x_i$ is the distance between measurements.

Since there are usually noise or measurement errors in measured data, it is often necessary to smooth the data, expecting that errors will be averaged out. Elementary smoothing is by simple averaging, where a value y_i is replaced by an average before the derivative is calculated. Examples include:

$$y_i \leftarrow \frac{y_{i+1} + y_i + y_{i-1}}{3}$$

$$y_i \leftarrow \frac{y_{i+2} + y_{i+1} + y_i + y_{i-1} + y_{i-2}}{5}$$

More information may be found in the literature under the topics linear filters, digital signal processing, and smoothing techniques.

Numerical Integration

Numerical integration requires a great deal of calculation and is usually done with the aid of a computer. All the methods described here, and many others, are widely available in packaged computer software. There is often a temptation to use whatever software is available without first checking that it really is appropriate. For this reason, it is important that the user be familiar with the methods being used and that he or she ensure that the error terms are tolerably small.

Trapezoid Rule If an interval $a \le x \le b$ is divided into subintervals $x_0, x_1, \ldots, x_n$, then the definite integral

$$\int_a^b f(x)\,dx$$

may be approximated by

$$\sum_{i=1}^{n} [f(x_i) + f(x_{i-1})]\frac{x_{i+1} - x_i}{2}$$

If the values x_i are equally spaced at distance h and if f_i is written for $f(x_i)$, then the above formula reduces to

$$[f_0 + 2f_1 + 2f_2 + \cdots + 2f_{n-1} + f_n]\frac{h}{2}$$

The error in the trapezoid rule is given by

$$|E_n| \le \frac{(b - a)^3 |f''(t)|}{12n^2}$$

where t is some value $a \le t \le b$.

Simpson's Rule The most widely used rule for numerical integration approximates the curve with parabolas. The interval $a < x < b$ must be divided into $n/2$ subintervals, each of length $2h$, where n is an even number. Using the notation above, the integral is approximated by

$$[f_0 + 4f_1 + 2f_2 + 4f_3 + \cdots + 4f_{n-1} + f_n]\frac{h}{3}$$

The error term for Simpson's rule is given by $|E_n| < nh^5 |f^{(4)}(t)|/180$, where $a < t < b$.

Simpson's rule is generally more accurate than the trapezoid rule.

Ordinary Differential Equations

Modified Euler Method Consider a first-order differential equation $dy/dx = f(x, y)$ and initial condition $y = y_0$ and $x = x_0$. Take x_i equally spaced, with $x_{i+1} - x_i = h$. Then the method is:

1. Set $n = 0$.
2. $y'_n = f(x_n, y_n)$ and $y'' = f_x(x_n, y_n) + y'_n f_y(x_n, y_n)$, where f_x and f_y denote partial derivatives.
3. $y'_{n+1} = f(x_{n+1}, y_{n+1})$.

Predictor steps:

4. For $n > 0$, $y^*_{n+1} = y_{n-1} + 2hy'_n$.
5. $y'^*_{n+1} = f(x_{n+1}, y^*_{n+1})$.

Corrector steps:

6. $y^\#_n + 1 = y_n + [y^*_{n+1} + y'_n]h/2$.
7. $y'^\#_{n+1} = f(x_{n+1}, y^\#_{n+1})$.
8. If required accuracy is not yet obtained for y_{n+1} and y'_{n+1}, then substitute $y^\#$ for y^*, in all its forms, and repeat the corrector steps. Otherwise, set $n = n + 1$ and return to step 2.

Other predictor-corrector methods are described in the literature.

Runge-Kutta Methods These make up a family of widely used methods for ordinary differential equations. Given $dy/dx = f(x, y)$ and h = interval size, third-order method (error proportional to h^4):

$$k_0 = hf(x_n)$$

$$k_1 = hf\left(x_n + \frac{h}{2}, y_n + \frac{k_0}{2}\right)$$

$$k_2 = hf(x_n + h, y_n + 2k_1 - k_0)$$

$$y_{n+1} = y_n + \frac{k_0 + 4k_1 + k_2}{6}$$

Higher-order Runge-Kutta methods are described in the literature. In general, higher-order methods yield smaller error terms.

Partial Differential Equations

Approximate solutions to partial differential equations require even more computational effort than ordinary differential equations. A typical problem involves finding the value of a function of two or more variables on the interior of a region, given the values of the function on the boundary of that region and also given a partial differential equation that the function must satisfy.

A typical solution strategy involves representing the continuous problem by its values on a finite set of points, called nodes, within the region, and representing the differential equation by difference equations on the value of the function at the nodes. The boundary value conditions are represented by assigning values to those nodes at or near the boundary of the region.

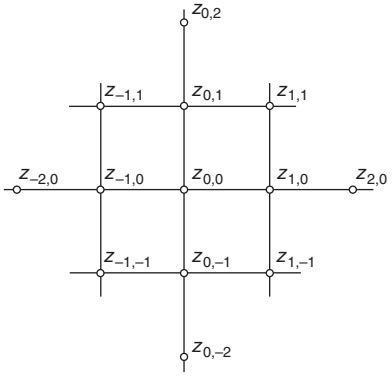

Fig. 2.1.113 Rectangular net.

The pattern of nodes within the region is called a net. A rectangular net is shown in Fig. 2.1.113. There is also an extensive theory of triangular nets. Some techniques use an irregular pattern of nodes, with the nodes more concentrated in more critical parts of the region. Such techniques are called finite element methods.

If the distance between nodes in a net is given by a, then the various partial derivatives at a value $z_{0,0} = f(x_0, y_0)$ may be given by

$$\frac{\partial z}{\partial x} \approx \frac{1}{2a}(z_{1,0} - z_{-1,0})$$

$$\frac{\partial z}{\partial y} \approx \frac{1}{2a}(z_{0,1} - z_{0,-1})$$

$$\frac{\partial^2 z}{\partial x^2} \approx \frac{1}{a^2}(z_{1,0} - 2z_{0,0} + z_{-1,0})$$

$$\frac{\partial^2 z}{\partial x \partial y} \approx \frac{1}{4a^2}(z_{1,1} - z_{-1,1} + z_{-1,-1} - z_{1,-1})$$

$$\frac{\partial^2 z}{\partial y^2} \approx \frac{1}{a^2}(z_{0,1} - 2z_{0,0} + z_{0,-1})$$

Other formulas are possible, and there are also formulas for higher order partial derivatives.

Applying the appropriate difference formulas to each node in a net gives an equation for each node. If there are n nodes, then n linear equations involving n unknowns arise. Though n is likely to be rather large, the system of linear equations is *sparse*, that is, most of the entries in the $n \times n$ matrix that describes the system are zero. Special methods exist for solving sparse systems of simultaneous linear equations relatively efficiently.

EXAMPLE. Solve the generalized Laplace equation

$$\nabla^2 f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} = g(x, y)$$

where $g(x, y)$ is a given function of x and y. At each point (x_i, y_j) on the interior of the region, we approximate the partial derivatives as

$$\frac{\partial^2 z}{\partial x^2} \approx \frac{1}{a^2}(z_{i+1,j} - 2z_{i,j} + z_{i-1,j}) \quad \text{and} \quad \frac{\partial^2 z}{\partial y^2} \approx \frac{1}{a^2}(z_{i,j+1} - 2z_{i,j} + z_{i,j-1}).$$

This gives a difference equation

$$\frac{1}{a^2}(z_{i+1,j} + z_{i-1,j} + z_{i,j+1} + z_{i,j-1} - 4z_{i,j}) = g(x_i, y_j)$$

that must be satisfied at each point (x_i, y_j).

Relaxation methods are a family of techniques for finding approximate solutions to such systems of equations. They involve finding the points (x_i, y_j) for which the difference equations are farthest from being true, and adjusting or relaxing the value of $z_{i,j}$ so that the equation is satisfied at that point.

COMPUTER PROGRAMMING

Machine Types

Computers are machines used for automatically processing information represented by mechanical, electrical, or optical means. They may be classified as analog or digital according to the techniques used to represent and process the information. Analog computers represent information as physically measurable, continuous quantities and process the information by components that have been interconnected to form an analogous model of the problem to be solved. Digital computers, on the other hand, represent information as discrete physical states which have been encoded into symbolic formats, and process the information by sequences of operational steps which have been preplanned to solve the given problem.

When compared to analog computers, digital computers have the advantages of greater versatility in solving scientific, engineering, and commercial problems that involve numerical and nonnumerical information; of an accuracy dictated by significant digits rather than that which can be measured; and of exact reproducibility of results that stay unvitiated by small, random fluctuations in the physical signals. In the past, multiple-purpose analog computers offered advantages of speed and cost in solving a sophisticated class of complex problems dealing with networks of differential equations, but these advantages have disappeared with the advances in solid-state computers. Other than the

occasional use of analog techniques for embedding computations as part of a larger system, digital techniques now account almost exclusively for the technology used in computers.

Digital information may be represented as a series of incremental, numerical steps which may be manipulated to position control devices using stepping motors. Digital information may also be encoded into symbolic formats representing digits, alphabetic characters, arithmetic numbers, words, linguistic constructs, points, and pictures which may be processed by a variety of mechanized operators. Machines organized in this manner can handle a more general class of both numerical and nonnumerical problems and so form by far the most common type of digital machines. In fact, the term *computer* has become synonymous with this type of machine.

Digital Machines

Digital machines consist of two kinds of circuits: memory cells, which effectively act to delay signals until needed, and logical units, which perform basic Boolean operations such as AND, OR, NOT, XOR, NAND, and NOR. Memory circuits can be simply defined as units where information can be stored and retrieved on demand. Configurations assembled from the Boolean operators provide the macro operators and functions available to the machine user through encoded instructions.

Both data and the instructions for processing the data can be stored in memory. Each unit of memory has an address at which the contents can be retrieved, or "read." The *read* operation makes the contents at an address available to other parts of the computer without destroying the contents in memory. The contents at an address may be changed by a *write* operation which inserts new information after first nullifying the previous contents. Some types of memory, called read-only memory **(ROM),** can be read from but not written to. They can only be changed at the factory.

Abstractly, the address and the contents at the address serve roles analogous to a variable and the value of the variable. For example, the equation $z = x + y$ specifies that the value of x added to the value of y will produce the value of z. In a similar way, the machine instruction whose format might be:

add, address 1, address 2, address 3

will, when executed, add the contents at address 1 to the contents at address 2 and store the result at address 3. As in the equation where the variables remain unaltered while the values of the variables may be changed, the addresses in the instruction remain unaltered while the contents at the address may change.

Computers differ from other kinds of mechanical and electrical machines in that computers perform work on information rather than on forces and displacements. A common form of information is numbers. Numbers can be encoded into a mechanized form and processed by the four rules of arithmetic ($+$, $-$, $\times$, $\div$). But numbers are only one kind of information that can be manipulated by the computer. Given an encoded alphabet, words and languages can be formed and the computer can be used to perform such processes as information storage and retrieval, translation, and editing. Given an encoded representation of points and lines, the computer can be used to perform such functions as drawing, recognizing, editing, and displaying graphs, patterns, and pictures.

Because computers have become easily accessible, engineers and scientists from every discipline have reformatted their professional activities to mechanize those aspects which can supplant human thought and decision. In this way, mechanical processes can be viewed as augmenting human physical skills and strength, and information processes can be viewed as augmenting human mental skills and intelligence.

COMPUTER DATA STRUCTURES

Binary Notation

Digital computers represent information by strings of digits which assume one of two values: 0 or 1. These units of information are called **bits,** a word contracted from the term *binary digits.* A string of bits may represent either numerical or nonnumerical information.

In order to achieve efficiency in handling the information, the computer groups the bits together into units containing a fixed number of bits which can be referenced as discrete units. By encoding and formatting these units of information, the computer can act to process them. Units of 8 bits, called **bytes,** are common. A byte can be used to encode the basic symbolic characters which provide the computer with input-output information such as the alphabet, decimal digits, punctuation marks, and special characters.

Bit groups may be organized into larger units of 4 bytes (32 bits) called **words,** or even larger units of 8 bytes called *double words;* and sometimes into smaller units of 2 bytes called *half words.* Besides encoding numerical information and other linguistic constructs, these units are used to encode a repertoire of machine instructions. Older machines and special-purpose machines may have other word sizes.

Computers process numerical information represented as binary numbers. The binary numbering system uses a positional notation similar to the decimal system. For example, the decimal number 596.37 represents the value $5 \times 10^2 + 9 \times 10^1 + 6 \times 10^0 + 3 \times 10^{-1} + 7 \times 10^{-2}$. The value assigned to any of the 10 possible digits in the decimal system depends on its position relative to the decimal point (a weight of 10 to zero or positive exponent is assigned to the digits appearing to the left of the decimal point, and a weight of 10 to a negative exponent is applied to digits to the right of the decimal point). In a similar manner, a binary number uses a radix of 2 and two possible digits: 0 and 1. The radix point in the positional notation separates the whole from the fractional part of the number, just as in the decimal system. The binary number 1011.011 represents a value $1 \times 2^3 + 0 \times 2^2 + 1 \times 2^1 + 1 \times 2^0 + 0 \times 2^{-1} + 1 \times 2^{-2} + 1 \times 2^{-3}$.

The operators available in the computer for setting up the solution of a problem are encoded into the instructions of the machine. The instruction repertoire always includes the usual arithmetic operators to handle numerical calculations. These instructions operate on data encoded in the binary system. However, this is not a serious operational problem, since the user specifies the numbers in the decimal system or by mnemonics, and the computer converts these formats into its own internal binary representation.

On occasions when one must express a number directly in the binary system, the number of digits needed to represent a numerical value becomes a handicap. In these situations, a radix of 8 or 16 (called the **octal** or **hexadecimal** system, respectively) constitutes a more convenient system. Starting with the digit to the left or with the digit to the right of the radix point, groups of 3 or 4 binary digits can be easily converted to equivalent octal or hexadecimal digits, respectively. Appending nonsignificant 0s as needed to the rightmost and leftmost part of the number to complete the set of 3 or 4 binary digits may be necessary. Table 2.2.1 lists the conversions of binary digits to their equivalent octal and hexadecimal representations. In the hexadecimal system, the letters A through F augment the set of decimal digits to represent the digits for 10 through 15. The following examples illustrate the conversion

Table 2.2.1 Binary-Hexadecimal and Binary-Octal Conversion

Binary	Hexadecimal	Binary	Octal
0000	0	000	0
0001	1	001	1
0010	2	010	2
0011	3	011	3
0100	4	100	4
0101	5	101	5
0110	6	110	6
0111	7	111	7
1000	8		
1001	9		
1010	A		
1011	B		
1100	C		
1101	D		
1110	E		
1111	F		

Table 2.2.2 Schemes for Encoding Decimal Digits

Decimal digit	BCD	Excess-3	4221 code
0	0000	0011	0000
1	0001	0100	0001
2	0010	0101	0010
3	0011	0110	0011
4	0100	0111	0110
5	0101	1000	1001
6	0110	1001	1100
7	0111	1010	1101
8	1000	1011	1110
9	1001	1100	1111

between binary numbers and octal or hexadecimal numbers using the table.

binary number	011	011	110	101	.	001	111	100
octal number	3	3	6	5	.	1	7	4
binary number		0110	1111	0101	.	0011	1110	
hexadecimal number		6	F	5	.	3	E	

Formats for Numerical Data

Three different formats are used to represent numerical information internal to the computer: fixed-point, encoded decimal, and floating-point.

A word or half word in fixed-point format is given as a string of 0s and 1s representing a binary number. The program infers the position of the radix point (immediately to the right of the word representing integers, and immediately to the left of the word representing fractions). Algebraic numbers have several alternate forms: 1's complement, 2's complement, and signed-magnitude. Most often 1's and 2's complement forms are adopted because they lead to a simplification in the hardware needed to perform the arithmetic operations. The sign of a 1's complement number can be changed by replacing the 0s with 1s and the 1s with 0s. To change the sign of a 2's complement number, reverse the digits as with a 1's-complement number and then add a 1 to the resulting binary number. Signed-magnitude numbers use the common representation of an explicit + or − sign by encoding the sign in the leftmost bit as a 0 or 1, respectively.

Many computers provide an encoded-decimal representation as a convenience for applications needing a decimal system. Table 2.2.2 gives three out of over 8000 possible schemes used to encode decimal digits in which 4 bits represent each decade value. Many other codes are possible using more bits per decade, but four bits per decimal digit are common because two decimal digits can then be encoded in one byte. The particular scheme selected depends on the properties needed by the devices in the application.

The floating-point format is a mechanized version of the scientific notation ($\pm M \times 10^{\pm E}$, where $\pm M$ and $\pm E$ represent the signed mantissa and signed exponent of the number). This format makes possible the use of a machine word to encode a large range of numbers. The signed mantissa and signed exponent occupy a portion of the word. The exponent is implied as a power of 2 or 16 rather than of 10, and the radix point is implied to the left of the mantissa. After each operation, the machine adjusts the exponent so that a nonzero digit appears in the most significant digit of the mantissa. That is, the mantissa is **normalized** so that its value lies in the range of $1/b \leq M < 1$ where b is the implied base of the number system (e.g.: $1/2 \leq M < 1$ for a radix of 2, and $1/16 \leq M < 1$ for a radix of 16). Since the zero in this notation has many logical representations, the format uses a standard recognizable form for zero, with a zero mantissa and a zero exponent, in order to avoid any ambiguity.

When calculations need greater precision, floating-point numbers use a two-word representation. The first word contains the exponent and mantissa as in the one-word floating point. Precision is increased by appending the extra word to the mantissa. The terms **single precision** and **double precision** make the distinction between the one- and two-word representations for floating-point numbers, although *extended precision* would be a more accurate term for the two-word form since the added word more than doubles the number of significant digits.

The equivalent decimal precision of a floating-point number depends on the number n of bits used for the unsigned mantissa and on the implied base b (binary, octal, or hexadecimal). This can be simply expressed in equivalent decimal digits p as: $0.0301\ (n - \log_2 b) < p < 0.0301\ n$. For example, a 32-bit number using 7 bits for the signed exponent of an implied base of 16, 1 bit for the sign of the mantissa, and 24 bits for the value of the mantissa gives a precision of 6.02 to 7.22 equivalent decimal digits. The fractional parts indicate that some 7-digit and some 8-digit numbers cannot be represented with a mantissa of 24 bits. On the other hand, a double-precision number formed by adding another word of 32 bits to the 24-bit mantissa gives a precision of 15.65 to 16.85 equivalent decimal digits.

The range r of possible values in floating-point notation depends on the number of bits used to represent the exponent and the implied radix. For example, for a signed exponent of 7 bits and an implied base of 16, then $16^{-64} \leq r \leq 16^{63}$.

	Bits	b_7	0	0	0	0	1	1	1	1

Fig. 2.2.1 ASCII code set.

Formats of Nonnumerical Data

Logical elements, also called **Boolean** elements, have two possible values which simply represent 0 or 1, true or false, yes or no, OFF or ON, etc. These values may be conveniently encoded by a single bit.

A large variety of codes are used to represent the alphabet, digits, punctuation marks, and other special symbols. The most popular ones are the 7-bit ASCII code and the 8-bit EBCDIC code. ASCII and EBCDIC find their genesis in punch-tape and punch-card technologies, respectively, where each character was encoded as a combination of punched holes in a column. Both have now evolved into accepted standards represented by a combination of 0s and 1s in a byte.

Figure 2.2.1 shows the ASCII code. (ASCII stands for American Standard Code for Information Interchange.) The possible 128 bit patterns divide the code into 96 graphic characters (although the codes 0100000 and 1111111 do not represent any printable graphic symbol) and 32 control characters which represent nonprintable characters used in communications, in controlling peripheral machines, or in expanding the code set with other characters or fonts. The graphic codes and the control codes are organized so that subsets of usable codes with fewer bits can be formed and still maintain the pattern.

Data Structure Types

The above types of numerical and nonnumerical data formats are recognized and manipulated by the hardware operations of the computer. Other more complex data structures may be programmed into the

computer by building upon these primitive data types. The programmable data structures might include arrays, defined as ordered lists of elements of identical type; **sets,** defined as unordered lists of elements of identical type; **records,** defined as ordered lists of elements that need not be of the same type; **files,** defined as sequential collections of identical records; and **databases,** defined as organized collections of different records or file types.

COMPUTER ORGANIZATION

Principal Components

The principal components of a computer system consist of a central processing unit (referred to as the **CPU** or platform), its working memory, user interface, file storage, and a collection of add-ons and peripheral devices. A computer system can be viewed as a library of collected data and packages of assembled sequences of instructions that can be executed in the prescribed order by the CPU to solve specific problems or perform utility functions for the users. These sequences are variously called programs, subprograms, routines, subroutines, procedures, functions, etc. Collectively they are called **software** and are directly accessible to the CPU through the working memory. The file devices act analogously to a bookshelf—they store information until it is needed. Only after a program and its data have been transferred from the file devices or from peripheral devices to the working memory can the individual instructions and data be addressed and executed to perform their intended functions.

The CPU functions to monitor the flow of data and instructions into and out of memory during program execution, control the order of instruction execution, decode the operation, locate the operand(s) needed, and perform the operation specified. Two characteristics of the memory and storage components dictate the roles they play in the computer system. They are **access time,** defined as the elapsed time between the instant a read or write operation has been initiated and the instant the operation is completed, and size, defined by the number of bytes in a module. The faster the access time, the more costly per bit of memory or storage, and the smaller the module. The principal types of memory and storage components from the fastest to the slowest are registers which operate as an integral part of the CPU, cache and main memory which form the working memory, and mass and archival storage which serve for storing files.

The interrelationships among the components in a computer system and their primary performance parameters will be given in context in the following discussion. However, hundreds of manufacturers of computers and computer products have a stake in advancing the technology and adding new functionality to maintain their competitive edge. In such an environment, no performance figures stay current. With this caveat, performance figures given should not be taken as absolutes but only as an indication of how each component contributes to the performance of the total system.

Throughout the discussion (and in the computer world generally), prefixes indicating large numbers are given by the symbols k for kilo (10^3), M for mega (10^6), G for giga (10^9), and T for tera (10^{12}). For memory units, however, these symbols have a slightly altered meaning. Memories are organized in binary units whereby powers of two form the basis for all addressing schemes. According, k refers to a memory size of 1024 (2^{10}) units. Similarly M refers to 1024^2 (1,048,576), G refers to 1024^3, and T refers to 1024^4. For example, 1-Mbyte memory indicates a size of 1,048,576 bytes.

Memory

The main memory, also known as random access memory **(RAM),** is organized into fixed size bit cells (words, bytes, half words, or double words) which can be located by address and whose contents contain the instructions and data currently being executed. The CPU acts to address the individual memory cells during program execution and transfers their contents to and from its internal registers.

Optionally, the working memory may contain an auxiliary memory, called **cache,** which is faster than the main memory. Cache operates on the premise that data and instructions that will shortly be needed are located near those currently being used. If the information is not found in the cache, then it is transferred from the main memory. The effective average access times offered by the combined configuration of RAM and cache results in a more powerful (faster) computer.

Central Processing Unit

The CPU makes available a repertoire of instructions which the user uses to set up the problem solutions. Although the specific format for instructions varies among machines, the following illustrates the pattern:

name: operator, operand(s)

The name designates an address whose contents contain the operator and one or more operands. The operator encodes an operation permitted by the hardware of the CPU. The operand(s) refer to the entities used in the operation which may be either data or another instruction specified by address. Some instructions have implied operand(s) and use the bits which would have been used for operand(s) to modify the operator.

To begin execution of a program, the CPU first loads the instructions serially by address into the memory either from a peripheral device, or more frequently, from storage. The internal structure of the CPU contains a number of memory registers whose number, while relatively few, depend on the machine's organization. The CPU acts to transfer the instructions one at a time from memory into a designated register where the individual bits can be interpreted and executed by the hardware. The actions of the following steps in the CPU, known as the *fetch-execute cycle,* control the order of instruction execution.

Step 1: Manually or automatically under program control load the address of the starting instruction into a register called the program register (PR).

Step 2: Fetch and copy the contents at the address in PR into a register called the program content register (PCR).

Step 3: Prepare to fetch the next instruction by augmenting PR to the next address in normal sequence.

Step 4: Interpret the instruction in PCR, retrieve the operands, execute the encoded operation, and then return to step 2. Note that the executed instruction may change the address in PR to start a different instruction sequence.

The speed of machines can be compared by calculating the average execution time of an instruction. Table 2.2.3 illustrates a typical instruction mix used in calculating the average. The instruction mix gives the relative frequency each instruction appears in a compiled list of typical programs and so depends on the types of problems one expects the machine to solve (e.g., scientific, commercial, or combination). The equation

$$t = \sum_i w_i t_i$$

expresses the average instruction execution time t as a function of the execution time t_i for instruction i having a relative frequency w_i in the instruction mix. The reciprocal of t measures the processor's performance as the average number of instructions per second (ips) it can execute.

Table 2.2.3 Instruction Mix

i	Instruction type	Weight w_i
1	Add: Floating point	0.07
2	Fixed point	0.16
3	Multiple: Floating point	0.06
4	Load/store register	0.12
5	Shift: One character	0.11
6	Branch: Conditional	0.21
7	Unconditional	0.17
8	Move 3 words in memory	0.10
	Total	1.00

For machines designed to support scientific and engineering calculations, the floating-point arithmetic operations dominate the time needed to execute an average instruction mix. The speed for such machines is

given by the average number of floating-point operations which can be executed per second (flops). This measure, however, can be misleading in comparing different machine models. For example, when the machine has been configured with a cluster of processors cooperating through a shared memory, the rate of the configuration (measured in flops) represents the simple sum of the individual processors' flops rates. This does not reflect the amount of parallelism that can be realized within a given problem.

To compare the performance of different machine models, users often assemble and execute a suite of programs which characterize their particular problem load. This idea has been refined so that in 1992 two suites of **benchmark** programs representing typical scientific, mathematical, and engineering applications were standardized: Specint92 for integer operations, and Specfp92 for floating-point operations. Since these benchmark programs were established, many more standardized benchmarks have been created to model critical workloads and applications, and the set is constantly being revised and expanded. Performance ratings for computers are often reported on the basis of results from running a selected subset of the available benchmark programs.

Computer performance depends on a number of interrelated factors used in their design and fabrication, among them compactness, bus size, clock frequency, instruction set size, and number of coprocessors.

The speed that energy can be transmitted through a wire, bounded theoretically at 3×10^{10} cm/s, limits the ultimate speed at which the electronic circuits can operate. The further apart the electronic elements are from each other, the slower the operations. Advances in integrated circuits have produced compact microprocessors operating in the nanosecond range.

The microprocessor's bus size (the width of its data path, or the number of bits that can be sent simultaneously in parallel) affect its performance in two ways: by the number of memory cells that can be directly addressed, and by the number of bits each memory reference can fetch and process at a time. For example, a 16-bit microprocessor can reference 2^{16} 16-bit memory cells and process 16 bits at a time. In order to handle the individual bits, the number of transistors that must be packed into the microprocessor goes up geometrically with the width of the data path. The earliest microprocessors were 8-bit devices, meaning that every memory reference retrieved 8 bits. To retrieve more bits, say 16, 32, or 64 bits, the 8-bit microprocessor had to make multiple references. Microprocessors have become more powerful as the packing technology has improved.

While normally the circuits operate asynchronously, a computer clock times the sequencing of the instructions. Clock speed is given in hertz (Hz, one cycle per second). Each instruction takes an integral number of cycles to complete, with one cycle being the minimum. If an instruction completes its operations in the middle of a cycle, the start of the next instruction must wait for the beginning of the next cycle.

Two schemes are used to implement the computer instruction set in the microprocessors. The more traditional complex instruction set computer (CISC) microprocessors implement by hard-wiring some 300 instruction types. Strange to say, the faster alternate-approach reduced instruction set computer (RISC) implements only about 10 to 30 percent of the instruction types by hard wiring, and implements the remaining more-complex instructions by programming them at the factory into read-only memory. Since the fewer hard-wired instructions are more frequently used and can operate faster in the simpler, more-compact RISC environment, the average instruction time is reduced.

To achieve even greater effectiveness and speed calls for more complex coordination in the execution of instructions and data. In one scheme, microprocessors in a cluster share a common memory to form the machine organization (a multiprocessor or parallel processor). The total work which may come from a single program or independent programs is parceled out to the individual machines which operate independently but are coordinated to work in parallel with the other machines in the cluster. Faster speeds can be achieved when the individual processors can work on different parts of the problem or can be assigned to those parts of the problem solution for which they have been especially designed (e.g., input-output operations or computational operations). Two other schemes, pipelining and array processing, divide an instruction into the separate tasks that must be performed to complete its execution. A pipelining machine executes the tasks concurrently on consecutive pieces of data. An array processor executes the tasks of the different instructions in a sequence simultaneously and coordinates their completion (which might mean abandoning a partially completed instruction if it had been initiated prematurely). These schemes are usually associated with the larger and faster machines.

User Interface

The user interface is provided to enable the computer user to initiate or terminate tasks, to interrogate the computer to determine the status of tasks during execution, to give and receive instructions, and to otherwise monitor the operation of the system.

The user interface is continuously evolving, but commonly consists of a relatively slow speed keyboard input, a display, and a pointing device. Important display characteristics for usability are the size of the screen and the resolution. The display has its own memory, which refreshes and controls the display. Examples of display devices that have seen common usage are cathode-ray tube (CRT) displays, flat-panel displays, and thin-film displays. For convenience and manual speed, a pointing device such as a mouse, trackball, or touchpad can be used to control the movement of the cursor on the display. The pointing device can also be used to locate and select options available on the display.

File Devices

File devices serve to store libraries of directly accessible programs and data in electronically or optically readable formats. The file devices record the information in large blocks rather than by individual addresses. To be used, the blocks must first be transferred into the working memory. Depending on how selected blocks are located, file devices are categorized as sequential or direct-access. On **sequential** devices the computer locates the information by searching the file from the beginning. Direct-access devices, on the other hand, position the read-write mechanism directly at the location of the needed information. Searching on these devices works concurrently with the CPU and the other devices making up the computer configuration.

Magnetic or **optical disks** that offer a wide choice of options form the commercial direct-access devices. Some file devices are read only and are used to deliver programs or data to be installed or only referenced by the user. Examples of read-only devices are CD-ROM and DVD-ROM. Other file devices can be both read from and written to. Example of read-write devices are magnetic disk drives, CD RJW drives, and DVD-RW drives. The recording surface consists of a platter (or platters) of recording material mounted on a common spindle rotated at high speed. The read-write heads may be permanently positioned along the radius of the platter or may be mounted on a common arm that can be moved radially to locate any specified track of information. Information is recorded on the **tracks** circumferentially using fixed-size blocks called pages or sectors. **Pages** divide the storage and memory space alike into blocks of 4096 bytes so that program transfers can be made without creating unusable space. **Sectors** nominally describe the physical division of the storage space into equal segments for easier positioning of the read-write heads.

The access time for retrieving information from a disk depends on three separately quoted factors, called seek time, latency time, and transfer time. **Seek time** gives the time needed to position the read-write heads from their current track position to the track containing the information. Since the faster fixed-head disks require no radial motion, only latency and transfer time need to be factored into the total access time for these devices. **Latency time** is the time needed to locate the start of the information along the circumferential track. This time depends on the speed of revolution of the disk, and, on average, corresponds to the time required to revolve the platter half a turn. The average latency time can be reduced by repeating the information several times around the track. **Transfer time,** usually quoted as a rate, gives the rate at which information can be transferred to memory after it has been located. There is a large variation in transfer rates depending on the disk system selected.

Computer architects sometimes refer to file storage as **mass storage** or **archival storage,** depending on whether or not the libraries can be kept off-line from the system and mounted when needed. Disk drives with mountable platter(s) and tape drives constitute the archival storage. Sealed disks that often have fixed heads for faster access are the medium of choice for mass storage.

Peripheral Devices and Add-ons

Peripheral devices function as self-contained external units that work on line to the computer to provide or receive information or to control the flow of information. Add-ons are a special class of units whose circuits can be integrated into the circuitry of the computer hardware to augment the basic functionality of the processors. Section 15 covers the electronic technology associated with these devices.

An input device may be defined as any device that provides a machine-readable source of information. For engineering work, the most common forms of input are touch-tone dials, mark sensing, bar codes, and keyboards (usually in conjunction with a printing mechanism or video scope). Many bench instruments have been reconfigured to include digital devices to provide direct input to computers. Because of the datahandling capabilities of the computer, these instruments can be simpler, smaller, and less expensive than the hand instruments they replace. New devices have also been introduced: devices for visual measurement of distance, area, speed, and coordinate position of an object; or for inspecting color or shades of gray for computer-guided vision. Other methods of input that are finding greater acceptance include handwriting recognition, printed character recognition, voice digitizers, and picture digitizers.

Traditionally, output devices play the role of producing displays for the interpretation of results. A large variety of printers, graphical plotters, video displays, and audio sets have been developed for this purpose.

A variety of actuators have been developed for driving control mechanisms. For complex numerical control, programmable controllers (called PLCs) can simultaneously control and update data from multiple tasks. These electronically driven mechanisms and controllers, working with input devices, make possible systems for automatic testing of products, real-time control, and robotics with learning and adaptive capabilities.

Computer Sizes

Computer size refers not only to the physical size but also to the number of electronics elements in the system, and so reflects the performance of the system. Between the two ends of the spectrum from the largest and fastest to the smallest and slowest are machines that vary in speed and complexity. Although no nomenclature has been universally adopted that indicates computer size, the following descriptions illustrate a few generally understood terms used for some common configurations. The choice of which computer is appropriate often requires serious evaluation. In the cases where serious evaluation is required, it is necessary to evaluate common performance benchmarks for the machine. In addition, it may be necessary to evaluate the machine by using a mix of applications designed to simulate current usage of existing machines or the expected usage of the proposed machine.

Personal computers (PCs) have been made possible by the advances in solid-state technology. The name applies to computers that can fit the total complement of hardware on a desktop and operate as stand-alone systems so as to provide immediate dedicated services to an individual user. This popular computer size has been generally credited for spreading computer literacy in today's society. Because of its commercial success, many peripheral devices, add-ons, and software products have been (and are continually being) developed. Laptop PCs are personal computers that have the low weight and size of a briefcase and can easily be transported when peripherals are not immediately needed.

The term **workstation** describes computer systems which have been designed to support complex engineering, scientific, or business applications in a professional environment. Although a top-of-the-line PC or a PC connected as a peripheral to another computer can function like a workstation, one can expect a machine designed as a workstation to offer higher performance than a PC and to support the more specialized peripherals and sophisticated professional software. Nevertheless, the boundary between PCs and workstations changes as the technology advances.

Notebook PCs and the smaller sized **palmtop** PCs are portable, battery-operated machines. These machines find excellent use as portable PCs in some applications and as data acquisition systems. However their undersized keyboards and small displays may limit their usefulness for sustained operations.

Computers larger than a PC or a workstation, called **mainframes** (and sometimes minis or maxis, depending on size), serve to support multiusers and multiapplications. A remotely accessible computing center may house several mainframes which either operate alone or cooperate with each other. Their high speed, large memories, and high reliability allow them to handle complex programs and they have been especially well suited to applications that do not allow for any significant downtime such as banking operations, business transactions, and reservation systems.

At the upper extreme end of the computer spectrum is the **supercomputer,** the class of the fastest machines that can address large, complex scientific/engineering problems which cannot reasonably be transferred to other machines. Obviously this class of computer must have cache and main memory sizes and speeds commensurate with the speed of the platform. While mass memory sizes must also be large, computers which support large databases may often have larger memories than do supercomputers. Large, complex technical problems must be run with high-precision arithmetic. Because of this, performance is measured in double-precision flops. To realize the increasing demand for higher performance, the designers of supercomputers work at the edge of available technology, especially in the use of multiple processors. With multiple processors, however, performance depends as much on the time spent in communication between processors as on the computational speed of the individual processors. In the final analysis, to muster the supercomputer's inherent speed, the development of the software becomes the problem. Some users report that software must often be hand-tailored to the specific problem. The power of the machines, however, can replace years of work in analysis and experimentation.

DISTRIBUTED COMPUTING

Organization of Data Facilities

A distributed computer system can be defined as a collection of computer resources which are remotely located from each other and are interconnected to cooperate in providing their respective services. The resources include both the equipment and the software. Resources distributed to reside near the vicinity where the data is collected or used have an obvious advantage over centralization. But to provide information in a timely and reliable manner, these islands of automation must be integrated.

The size and complexity of an enterprise served by a distributed information system can vary from a single-purpose office to a multipleplant conglomerate. An enterprise is defined as a system which has been created to accomplish a mission in its environment and whose goals involve risk. Internally it consists of organized functions and facilities which have been prepared to provide its services and accomplish its mission. When stimulated by an external entity, the enterprise acts to produce its planned response. An enterprise must handle both the flow of material (goods) and the flow of information. The information system tracks the material in the material system, but itself handles only the enterprise's information.

The technology for distributing and integrating the total information system comes under the industrial strategy known as computer-integrated business (CIB) or computer-integrated manufacturing (CIM). The following reasons have been cited for developing CIB and CIM:

Most data generated locally has only local significance.
Data integrity resides where it is generated.

The quality and consistency of operational decisions demands not only that all parts of the system work with the same data but that they can receive it in a reliable and timely manner.

If a local processor fails, it may disrupt local operations, but the remaining system should continue to function independently.

Small cohesive processors can be best managed and maintained locally.

Through standards, selection of local processes can be made from the best products in a competitive market that can be integrated into the total system.

Obsolete processors can be replaced by processors implemented by more advance technology that conform to standards without the cost of tailoring the products to the existing system.

Figure 2.2.2 depicts the total information system of an enterprise. The database consists of the organized collection of data the processors use in their operations. Because of differences in their communication requirements, the automated procedures are shown separated into those used in the office and those used on the production floor. In a business environment, the front office operations and back office operations make this separation. While all processes have a critical deadline, the production floor handles real-time operations, defined as processes which must complete their response within a critical deadline or else the results of the operations become moot. This places different constraints on the local-area networks (LANs) that serve the communication needs within the office or within the production floor. To communicate with entities outside the enterprise, the enterprise uses a wide-area network (WAN), normally made up from available public network facilities. For efficient and effective operation, the processes must be interconnected by the communications to share the data in the database and so integrate the services provided.

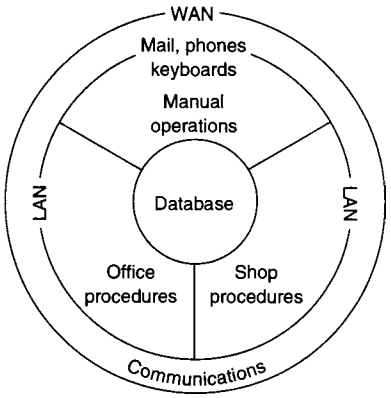

Fig. 2.2.2 Composite view of an enterprise's information system.

Communication Channels

A communication channel provides the connecting path for transmitting signals between a computing system and a remotely located application. Physically the channel may be formed by a wire line using copper, coaxial cable, or optical-fiber cable; or may be formed by a wireless line using radio, microwave, or communication satellites; or may be a combination of these lines.

Capacity, defined as the maximum rate at which information can be transmitted, characterizes a channel independent of the morphic line. Theoretically, an ideal noiseless channel that does not distort the signals has a channel capacity C given by:

$$C = 2W$$

where C is in pulses per second and W is the channel bandwidth. For digital transmission, the Hartley-Shannon theorem sets the capacity of a channel limited by the presence of gaussian noise such as the thermal noise inherent in the components. The formula:

$$C = W \log_2(1 + S/N)$$

gives the capacity C in bits/s in terms of the signal to noise ratio S/N and the bandwidth W. Since the signal to noise ratio is normally given in decibels divisible by 3 (e.g., 12, 18, 21, 24) the following formula provides a workable approximation to the formula above:

$$C = W(S/N)_{db}/3$$

where $(S/N)_{db}$ is the signal-to-noise ratio expressed in decibels. Other forms of noise, signal distortions, and the methods of signal modulation reduce this theoretical capacity appreciably.

Nominal transmission speeds for electronic channels vary from 1000 bits to almost 20 Mbits per second. Fiber optics, however, form an almost noise-free medium. The transmission speed in fiber optics depends on the amount a signal spreads due to the multiple reflected paths it takes from its source to its destination. Advances in fiber technology have reduced this spread to give unbelievable rates. Effectively, the speeds available in today's optical channels make possible the transmission over a common channel, using digital techniques, of all forms of information: text, voice, and pictures.

Besides agreeing on speed, the transmitter and receiver must agree on the mode of transmission and on the timing of the signals. For stations located remotely from each other, transmission occurs by organizing the bits into groups and transferring them, one bit after another, in a serial mode. One scheme, called **asynchronous** or start-stop transmission, uses separate start and stop signals to frame a small group of bits representing a character. Separate but identical clocks at the transmitter and receiver time the signals. For transmission of larger blocks at faster rates, the stations use **synchronous** transmission which embeds the clock information within the transmitted bits.

Communication Layer Model

Figure 2.2.3 depicts two remotely located stations that must cooperate through communication in accomplishing their respective tasks. The communications substructure provides the communication services needed by the application. The application tasks themselves, however, are outside the scope of the communication substructure. The distinction here is similar to that in a telephone system which is not concerned with the application other than to provide the needed communication service. The figure shows the communication facilities packaged into a hierarchical modular layer architecture in which each node contains identical kinds of functions at the same layer level. The layer functions represent abstractions of real facilities, but need not represent specific hardware or software. The entities at a layer provide communication

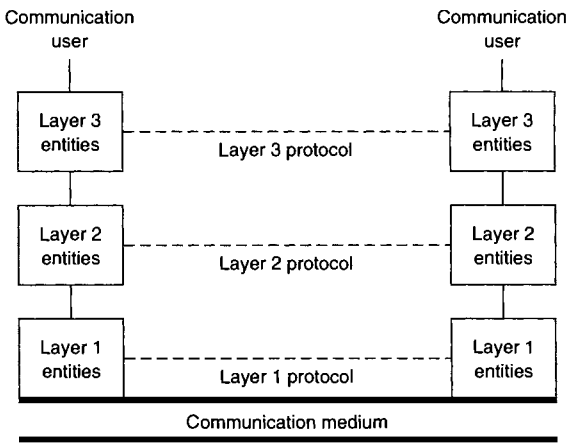

Fig. 2.2.3 Communication layer architecture.

services to the layer above or can request the services available from the layer below. The services provided or requested are available only at service points which are identified by addresses at the boundaries that interface the adjacent layers.

The top and bottom levels of the layered structure are unique. The topmost layer interfaces and provides the communication services to the noncommunication functions performed at a node dealing with the application task (the user's program). This layer also requests communication services from the layer below. The bottom layer does not have a lower layer through which it can request communication services. This layer acts to create and recognize the physical signals transmitted between the bottom entities of the communicating partners (it arranges the actual transmission). The medium that provides the path for the transfer of signals (a wire, usually) connects the service access points at the bottom layers, but itself lies outside the layer structure.

Virtual communication occurs between peer entities, those at the same level. Peer-to-peer communication must conform to layer protocol, defined as the rules and conventions used to exchange information. Actual physical communication proceeds from the upper layers to the bottom, through the communication medium (wire), and then up through the layer structure of the cooperating node.

Since the entities at each layer both transmit and receive data, the protocol between peer layers controls both input and output data, depending on the direction of transmission. The transmitting entities accomplish this by appending control information to each data unit that they pass to the layer below. This control information is later interpreted and removed by the peer entities receiving the data unit.

Communication Standards

Table 2.2.4 lists a few of the hundreds of forums seeking to develop and adopt voluntary standards or to coordinate standards activities. Often users establish standards by agreement that fixes some existing practice. The ISO, however, has described a seven-layer model, called the *Reference Model for Open Systems Interconnection* (OSI), for coordinating and expediting the development of new implementation standards. The term *open systems* refers to systems that allow devices to be interconnected and to communicate with each other by conforming to common implementation standards. The ISO model is not of itself an implementation standard nor does it provide a basis for appraising existing implementations, but it partitions the communication facilities into layers of related function which can be independently standardized by different teams of experts. Its importance lies in the fact that both vendors and users have agreed to provide and accept implementation standards that conform to this model.

Table 2.2.4 Some Groups Involved with Communication Standards

CCITT	Comité Consultatif de Télégraphique et Téléphonique
ISO	International Organization for Standardization
ANSI	American National Standards Institute
EIA	Electronic Industries Association
IEEE	Institute of Electrical and Electronics Engineers
MAP/TOP	Manufacturing Automation Protocols and Technical and Office Protocols Users Group
NIST	National Institute of Standards and Technology

The following lists the names the ISO has given the layers in its ISO model together with a brief description of their roles.

Application layer provides no services to the other layers but serves as the interface for the specialized communication that may be required by the actual application, such as file transfer, message handling, virtual terminal, or job transfer.

Presentation layer relieves the node from having to conform to a particular syntactical representation of the data by converting the data formats to those needed by the layer above.

Session layer coordinates the dialogue between nodes including arranging several sessions to use the same transport layer at one time.

Transport layer establishes and releases the connections between peers to provide for data transfer services such as throughput, transit delays, connection setup delays, error rate control, and assessment of resource availability.

Network layer provides for the establishment, maintenance, and release of the route whereby a node directs information toward its destination.

Data link layer is concerned with the transfer of information that has been organized into larger blocks by creating and recognizing the block boundaries.

Physical layer generates and detects the physical signals representing the bits, and safeguards the integrity of the signals against faulty transmission or lack of synchronization.

The IEEE has formulated several implementation standards for office or production floor LANs that conform to the lower two layers of the ISO model. The functions assigned to the ISO data link layer have been distributed over two sublayers, a logical link control (LLC) upper sublayer that generates and interprets the link control commands, and a medium access control (MAC) lower sublayer that frames the data units and acquires the right to access the medium. From this structure, the IEEE has formulated standards for the MAC sublayer and ISO physical layer combination, and a common standard for the LLC sublayer.

CSMA/CD standardized the access method developed by the Xerox Corporation under its trademark Ethernet. The nodes in the network are attached to a common bus. All nodes hear every message transmitted, but accept only those messages addressed to themselves. When a node has a message to transmit, it listens for the line to be free of other traffic before it initiates transmission. However, more than one node may detect the free line and may start to transmit. In this situation the signals will collide and produce a detectable change in the energy level present in the line. Even after a station detects a collision it must continue to transmit to make sure that all stations hear the collision (all data frames must be of sufficient length to be present simultaneously on the line as they pass each station). On hearing a collision, all stations that are transmitting wait a random length of time and then attempt to retransmit.

The MAP/TOP (Manufacturing Automation Protocols and Technical and Office Protocols) Users Group started under the auspices of General Motors and Boeing Information Systems and now has a membership of many thousands of national and international corporations. The corporations in this group have made a commitment to open systems that will allow them to select the best products through standards, agreed to by the group, that will meet their respective requirements. These standards have also been adopted by NIST for governmentwide use under the title Government Open Systems Interconnections Profile (GOSIP).

The common carriers who offer WAN communication services through their public networks have also developed **packet-switching** networks for public use. Packet switching transmits data in a purely digital format, which, when embellished, can replace the common circuit-switching technology used in analog communications such as voice. A packet is a fixed-sized block of digital data with embedded control information. The network serves to deliver the packets to their destination in an efficient and reliable manner.

Wireless network capabilities for computers based on the IEEE 802.11 set of standards evolved rapidly. The 802.11 standards enabled the implementation of wireless LAN having a performance comparable to that of wired LAN. The wireless LAN network is a set of wireless access points attached to a LAN that allow computers access the LAN. The coverage of the wireless access points can overlap allowing mobility within a region of coverage and allowing transfer from one access point to another if the computer is moved from one coverage region to another.

RELATIONAL DATABASE TECHNOLOGY

Design Concepts

As computer hardware has evolved from small working memories and tape storage to large working memories and large disk storage, so has database technology moved from accessing and processing of a single,

sequential file to that of multiple, random-access files. A **relational database** can be defined as an organized collection of interconnected tables or records. The records appear like the flat files of older technology. In each record the information is in columns (fields) which identify attributes, and rows (tuples) which list particular instances of the attributes. One column (or more), known as the **primary key,** identifies each row. Obviously, the primary key must be unique for each row.

If the data is to be handled in an efficient and orderly way, the records cannot be organized in a helter-skelter fashion such as simply transporting existing flat files into relational tables. To avoid problems in maintaining and using the database, redundancy should be eliminated by storing each fact at only one place so that, when making additions or deletions, one need not worry about duplicates throughout the database. This goal can be realized by organizing the records into what is known as the *third normal form.* A record is in the third normal form if and only if all nonkey attributes are mutually independent and fully dependent on the primary key.

The advantages of relational databases, assuming proper normalization, are:

Each fact can be stored exactly once.
The integrity of the data resides locally, where it is generated and can best be managed.
The tables can be physically distributed yet interconnected.
Each user can be given his/her own private view of the database without altering its physical structure.
New applications involving only a part of the total database can be developed independently.
The system can be automated to find the best path through the database for the specified data.
Each table can be used in many applications by employing simple operators without having to transfer and manipulate data superfluous to the application.
A large, comprehensive system can evolve from phased design of local systems.
New tables can be added without corrupting everyone's view of the data.
The data in each table can be protected differently for each user (read-only, write-only).
The tables can be made inaccessible to all users who do not have the right to know.

Relational Database Operators

A database system contains the structured collection of data, an on-line catalog and dictionary of data items, and facilities to access and use the data. The system allows users to:

Add new tables
Remove old tables
Insert new data into existing tables
Delete data from existing tables
Retrieve selected data
Manipulate data extracted from several tables
Create specialized reports

As might be expected, these systems include a large collection of operators and built-in functions in addition to those normally used in mathematics. Because of the similarity between database tables and mathematical sets, special set-like operators have been developed to manipulate tables. Table 2.2.5 lists seven typical table operators. The list of functions would normally also include such things as count, sum, average, find the maximum in a column, and find the minimum in a column. A rich collection of report generators offers powerful and flexible capabilities for producing tabular listings, text, graphics (bar charts, pie charts, point plots, and continuous plots), pictorial displays, and voice output.

SOFTWARE ENGINEERING

Programming Goals

Software engineering encompasses the methodologies for analyzing program requirements and for structuring programs to meet the requirements over their life cycle. The objectives are to produce programs that are:

Well documented
Easily read
Proved correct
Bug- (error-) free
Modifiable and maintainable
Implementable in modules

Control-Flow Diagrams

A control-flow diagram, popularly known as a **flowchart,** depicts all possible sequences of a program during execution by representing the control logic as a directed graph with labeled nodes. The theory associated with flowcharts has been refined so that programs can be structured to meet the above objectives. Without loss of generality, the nodes in a flowchart can be limited to the three types shown in Fig. 2.2.4. A **function** may be either a *transformer* which converts input data values into output data values or a *transducer* which converts that data's morphological form. A label placed in the rectangle specifies the function's action. A **predicate** node acts to bifurcate the path through the node. A question labels the diamond representing a predicate node. The answer to the question yields a binary value: 0 or 1, yes or no, ON or OFF. One of the output lines is selected accordingly. A **connector** serves to rejoin separated paths. Normally the circle representing a connector does not contain a label, but when the flowchart is used to document a computer program it may be convenient to label the connector.

Structured programming theory models all programs by their flowcharts by placing minor restrictions on their lines and nodes. Specifically, a flowchart is called a **proper program** if it has precisely one input and one output line, and for every node there exists a path from the input line through the node to the output line. The restriction prohibiting multiple input or output lines can easily be circumvented by funneling the lines through collector nodes. The other restriction simply discards unwanted program structures, since a program with a path that does not reach the output may not terminate.

Table 2.2.5 Relational Database Operators

Operator	Input	Output
Select	A table and a condition	A table of all tuples that satisfy the given condition
Project	A table and an attribute	A table of all values in the specified attribute
Union	Two tables	A table of all unique tuples appearing in one table or the other
Intersection	Two tables	A table of all tuples the given tables have in common
Difference	Two tables	A table of all tuples appearing in the first and not in the second table
Join	Two tables and a condition	A table concatenating the attributes of the tuples that satisfy the given condition
Divide	A table, two attributes, and list of values	A table of values appearing in one specified attribute of the given table when the table has tuples that satisfies every value in the list in the other given attribute

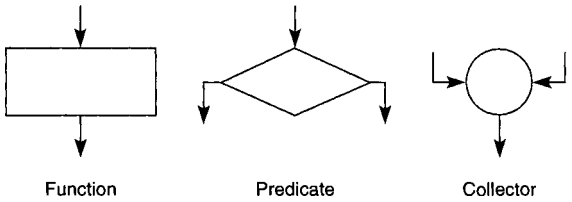

Fig. 2.2.4 Basic flowchart nodes.

Not all proper programs exhibit the desirable properties of meeting the objectives listed above. Figure 2.2.5 lists a group of proper programs whose graphs have been identified as being *well-structured* and useful as basic building blocks for creating other well-structured programs. The name assigned to each of these graph suggests the process each represents. CASE is just a convenient way of showing multiple IFTHENELSEs more compactly.

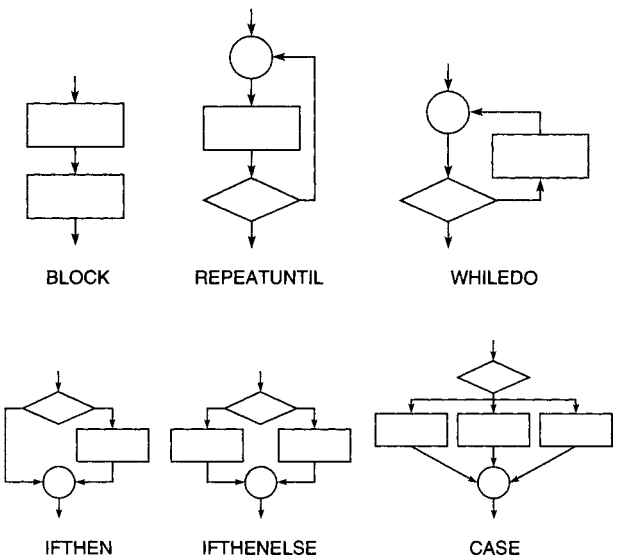

Fig. 2.2.5 Basic flowchart building blocks.

The **structured programming theorem** states: any proper program can be reconfigured to an equivalent program producing the same transformation of the data by a flowchart containing at most the graphs labeled BLOCK, IFTHENELSE, and REPEATUNTIL.

Every proper program has one input line and one output line like a function block. The synthesis of more complex well-structured programs is achieved by substituting any of the three building blocks mentioned in the theorem for a function node. In fact, any of the basic building blocks would do just as well. A program so structured will appear as a block of function nodes with a top-down control flow. Because of the top-down structure, the arrow points are not normally shown.

Figure 2.2.6 illustrates the expansion of a program to find the roots of $ax^2 + bx + c = 0$. The flowchart is shown in three levels of detail.

Data-Flow Diagrams

Data-flow diagrams structure the actions of a program into a network by tracking the data as it passes through the program. They depict the interworkings of a system by the processes performing the work and the communication between the processes. Data-flow diagrams have proved valuable in analyzing existing or new systems to determine the system requirements and in designing systems to meet those requirements.

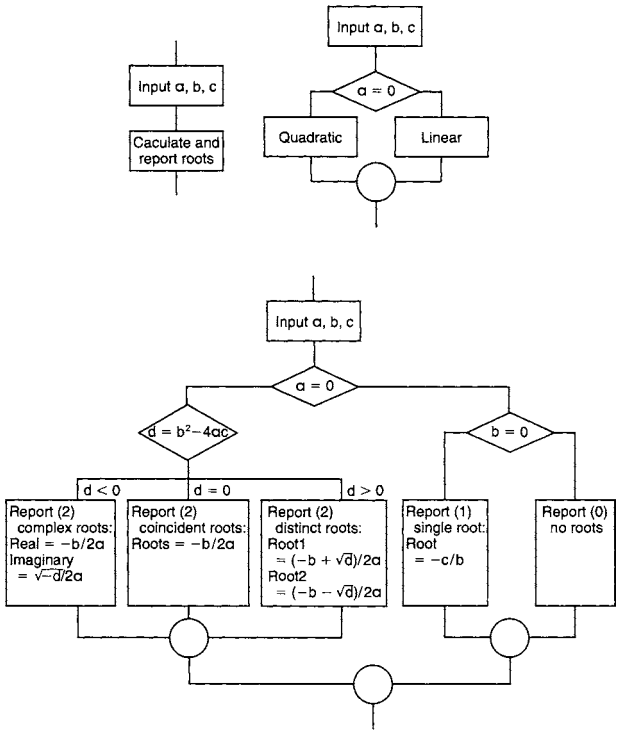

Fig. 2.2.6 Illustration of a control-flow diagram.

Figure 2.2.7 shows the four basic elements used to construct a data-flow diagram. The roles each element plays in the system are:

Rectangular boxes lie outside the system and represent the input data sources or output data sinks that communicate with the system. The sources and sinks are also called *terminators.*

Circles (bubbles) represent processes or actions performed by the system in accomplishing its function.

Twin parallel lines represent a data file used to collect and store data from among the processes or from a process over time which can be later recalled.

Arcs or vectors connect the other elements and represent data flows.

A label placed with each element makes clear its role in the system. The circles contain verbs and the other elements contain nouns. The arcs tie the system together. An arc between a terminator and a process represents input to or output from the system. An arc between two processes represents output from one process which is input to the other. An arc between a process and a file represents data gathered by the process and stored in the file, or retrieval of data from the file.

Analysis starts with a contextual view of the system studied in its environment. The contextual view gives the name of the system, the collection of terminators, and the data flows that provide the system inputs and outputs; all accompanied by a statement of the system objective. Details on the terminators and data they provide may also be described by text, but often the picture suffices. It is understood that the form of the input and output may not be dictated by the designer since they often involve organizations outside the system. Typical inputs in

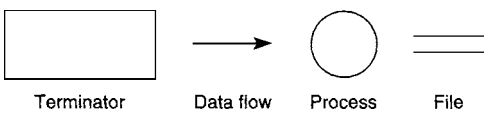

Fig. 2.2.7 Data-flow diagram elements.

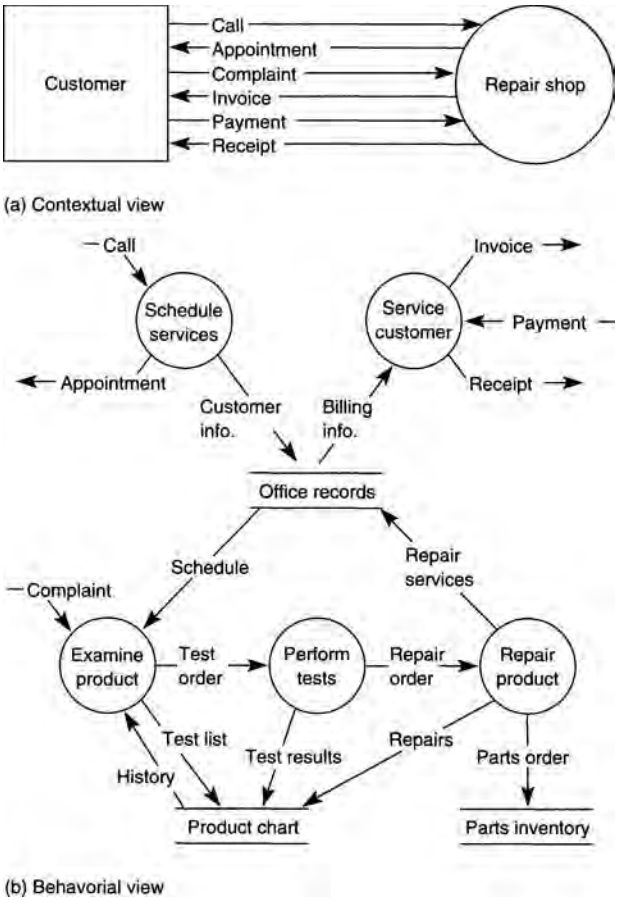

Fig. 2.2.8 Illustration of a data-flow diagram.

industrial systems include customer orders, payment checks, purchase orders, requests for quotations, etc. Figure 2.2.8*a* illustrates a context diagram for a repair shop.

Figure 2.2.8*b* gives many more operational details showing how the parts of the system interact to accomplish the system's objectives. The designer can restructure the internal processors and the formats of the data flows. The bubbles in a diagram can be broken down into further details to be shown in another data-flow diagram. This can be repeated level after level until the processes become manageable and understandable. To complete the system description, each bubble in the dataflow charts is accompanied by a control-flow diagram or its equivalent to describe the algorithm used to accomplish the actions and a data dictionary describing the items in the data flows and in the databases.

The techniques of data-flow diagrams lend themselves beautifully to the analysis of existing systems. In a complex system it would be unusual for an individual to know all the details, but all system participants know their respective roles: what they receive, whence they receive it, what they do, what they send, and where they send it. By carefully structuring interviews, the complete system can be synthesized to any desired level of detail. Moreover, each system component can be verified because what is sent from one process must be received by another and what is received by a process must be used by the process. To automate the total system or parts of the system, control bubbles containing transition diagrams can be implemented to control the timing of the processes.

SOFTWARE SYSTEMS

Software Techniques

Two basic operations form the heart of nonnumerical techniques such as those found in handling large database tables. One basic operation, called **sorting,** collates the information in a table by reordering the items by their key into a specified order. The other basic operation, called **searching,** seeks to find items in a table whose keys have the same or related value as a given argument. The search operation may or may not be successful, but in either case further operations follow the search (e.g., retrieve, insert, replace).

One must recognize that computers cannot do mathematics. They can perform a few basic operations such as the four rules of arithmetic, but even in this case the operations are approximations. In fact, computers represent long integers, long rationals, and all the irrational numbers like π and e only as approximations. While computer arithmetic and the computer representation of numbers exceed the precision one commonly uses, the size of problems solved in a computer and the number of operations that are performed can produce misleading results with large computational errors.

Since the computer can handle only the four rules of arithmetic, complex **functions** must be approximated by polynomials or rational fractions. A rational fraction is a polynomial divided by another polynomial. From these curve-fitting techniques, a variety of weighted-average formulas can be developed to approximate the **definite integral** of a function. These formulas are used in the procedures for solving differential and integral equations. While differentiation can also be expressed by these techniques, it is seldom used, since the errors become unacceptable.

Taking advantage of the machine's speed and accuracy, one can solve **nonlinear equations** by trial and error. For example, one can use the Newton-Raphson method to find successive approximations to the roots of an equation. The computer is programmed to perform the calculations needed in each iteration and to terminate the procedure when it has converged on a root. More sophisticated routines can be found in the libraries for finding real, multiple, and complex roots of an equation.

Matrix techniques have been commercially programmed into libraries of prepared modules which can be integrated into programs written in all popular engineering programming languages. These libraries not only contain excellent routines for solving **simultaneous linear equations** and the **eigenvalues** of characteristic matrices, but also embody procedures guarding against ill-conditioned matrices which lead to large computational errors.

Special matrix techniques called **relaxation** are used to solve partial differential equations on the computer. A typical problem requires setting up a grid of hundreds or thousands of points to describe the region and expressing the equation at each point by finite-difference methods. The resulting matrix is very sparse with a regular pattern of nonzero elements. The form of the matrix circumvents the need for handling large arrays of numbers in the computer and avoids problems in computational accuracy normally found in dealing with extremely large matrices.

The computer is an excellent tool for handling **optimization** problems. Mathematically these problems are formulated as problems in finding the maximum or minimum of a nonlinear equation. The excellent techniques that have been developed can deal effectively with the unique complexities these problems have, such as saddle points which represent both a maximum and a minimum.

Another class of problems, called **linear programming** problems, is characterized by the linear constraint of many variables which plot into regions outlined by multidimensional planes (in the two-dimensional case, the region is a plane enclosed by straight lines). Techniques have been developed to find the optimal solution of the variables satisfying some given value or cost objective function. The solution to the problem proceeds by searching the corners of the region defined by the constraining equations to find points which represent minimum points of a cost function or maximum points of a value function.

The best known and most widely used techniques for solving statistical problems are those of linear **statistics.** These involve the techniques of **least squares** (otherwise known as **regression**). For some problems these techniques do not suffice, and more specialized techniques involving nonlinear statistics must be used, albeit a solution may not exist.

Artificial intelligence (AI) is the study and implementation of programs that model knowledge systems and exhibit aspects of intelligence in problem solving. Typical areas of application are in learning, linguistics, pattern recognition, decision making, and theorem proving. In AI, the computer serves to search a collection of heuristic rules to find a match with a current situation and to make inferences or otherwise reorganize knowledge into more useful forms. AI techniques have been utilized to build sophisticated systems, called **expert systems,** to aid in producing a timely response in problems involving a large number of complex conditions.

Operating Systems

The operating system provides the services that support the needs that computer programs have in common during execution. Any list of services would include those needed to configure the resources that will be made available to the users, to attach hardware units (e.g., memory modules, storage devices, coprocessors, and peripheral devices) to the existing configuration, to detach modules, to assign default parameters to the hardware and software units, to set up and schedule users' tasks so as to resolve conflicts and optimize throughput, to control system input and output devices, to protect the system and users' programs from themselves and from each other, to manage storage space in the file devices, to protect file devices from faults and illegal use, to account for the use of the system, and to handle in an orderly way any exception which might be encountered during program execution. A well-designed operating system provides these services in a user-friendly environment and yet makes itself and the computer operating staff transparent to the user.

The design of a computer operating system depends on the number of users which can be expected. The focus of single-user systems relies on the monitor to provide a user-friendly system through dialog menus with icons, mouse operations, and templets. Table 2.2.6 lists some popular operating systems for PCs by their trademark names. The design of a multiuser system attempts to give each user the impression that he/she is the lone user of the system. In addition to providing the accoutrements of a user-friendly system, the design focuses on the order of processing the jobs in an attempt to treat each user in a fair and equitable fashion. The basic issues for determining the order of processing center on the selection of job queues: the number of queues (a simple queue or a mix of queues), the method used in scheduling the jobs in the queue (first come–first served, shortest job next, or explicit priorities), and the internal handling of the jobs in the queue (batch, multiprogramming, or timesharing).

Table 2.2.6 Some Popular PC Operating Systems

Trademark	Supplier
Windows	Microsoft Corp.
Unix	Unix Systems Laboratory Inc.
Sun/OS	Sun Microsystems Inc.
Macintosh	Apple Computer Inc.
Linux	Multiple suppliers

Batch operating systems process jobs in a sequential order. Jobs are collected in batches and entered into the computer with individual job instructions which the operating system interprets to set up the job, to allocate resources needed, to process the job, and to provide the input/output. The operating system processes each job to completion in the order it appears in the batch. In the event a malfunction or fault occurs during execution, the operating system terminates the job currently being executed in an orderly fashion before initiating the next job in sequence.

Multiprogramming operating systems process several jobs concurrently. A job may be initiated any time memory and other resources which it needs become available. Many jobs may be simultaneously active in the system and maintained in a partial state of completion. The order of execution depends on the priority assignments. Jobs are executed to completion or put into a wait state until a pending request for service has been satisfied. It should be noted that, while the CPU can execute only a single program at any moment of time, operations with peripheral and storage devices can occur concurrently.

Timesharing operating systems process jobs in a way similar to multiprogramming except for the added feature that each job is given a short slice of the available time to complete its tasks. If the job has not been completed within its time slice or if it requests a service from an external device, it is put into a wait status and control passes to the next job. Effectively, the length of the time slice determines the priority of the job.

Program Preparation Facilities

For the user, the crucial part of a language system is the grammar which specifies the language syntax and semantics that give the symbols and rules used to compose acceptable statements and the meaning associated with the statements. Compared to natural languages, computer languages are more precise, have a simpler structure, and have a clearer syntax and semantics that allows no ambiguities in what one writes or what one means. For a program to be executed, it must eventually be translated into a sequence of basic machine instructions.

The statements written by a user must first be put on some machine-readable medium or typed on a keyboard for entry into the machine. The translator **(compiler)** program accepts these statements as input and translates (compiles) them into a sequence of basic machine instructions which form the executable version of the program. After that, the translated (compiled) program can be run.

During the execution of a program, a run-time program must also be present in the memory. The purpose of the run-time system is to perform services that the user's program may require. For example, in case of a program fault, the run-time system will identify the error and terminate the program in an orderly manner.

Some language systems do not have a separate compiler to produce machine-executable instructions. Instead the run-time system interprets the statements as written, converts them into a pseudo-code, and executes the coded version.

Commonly needed functions are made available as prepared modules, either as an integral part of the language or from stored libraries. The documentation of these functions must be studied carefully to assure correct selection and utilization.

Languages may be classified as procedure-oriented or problem-oriented. With **procedure-oriented** languages, all the detailed steps must be specified by the user. These languages are usually characterized as being more verbose than problem-oriented languages, but are more flexible and can deal with a wider range of problems. **Problem-oriented** languages deal with more specialized classes of problems. The elements of problem-oriented languages are usually familiar to a knowledgeable professional and so are easier to learn and use than procedure-oriented languages.

The most elementary form of a procedure-oriented language is called an **assembler.** This class of language permits a computer program to be written directly in basic computer instructions using mnemonic operators and symbolic operands. The assembler's translator converts these instructions into machine-usable form.

A further refinement of an assembler permits the use of macros. A **macro** identifies, by an assigned name and a list of formal parameters, a sequence of computer instructions written in the assembler's format and stored in its subroutine library. The macroassembler includes these macro instructions in the translated program along with the instructions written by the programmer.

Besides these basic language systems there exists a large variety of other language systems. These are called higher-level language systems since they permit more complex statements than are permitted by a

macroassembler. They can also be used on machines produced by different manufacturers or on machines with different instruction repertoires.

One language of historical value is **ALGOL 60.** It is a landmark in the theoretical development of computer languages. It was designed and standardized by an international committee whose goal was to formulate a language suitable for publishing computer algorithms. Its importance lies in the many language features it introduced which are now common in the more recent languages which succeeded it and in the scientific notation which was used to define it.

FORTRAN (FORmula TRANslator) was one of the first languages catering to the engineering and scientific community where algebraic formulas specify the computations used within the program. It has been standardized several times. Each version has expanded the language features and has removed undesirable features which lead to unstructured programs.

The **PASCAL** language couples the ideas of ALGOL 60 to those of structured programming. By allowing only appropriate statement types, it guarantees that any program written in the language will be well structured. In addition, the language introduced new data types and allows programmers to define new complex data structures based on the primitive data types.

The definition of the **Ada** language was sponsored by the Department of Defense as an all-encompassing language for the development and maintenance of very large, software-intensive projects over their life cycle. While it meets software engineering objectives in a manner similar to Pascal, it has many other features not normally found in programming languages. Like other attempts to formulate very large all-inclusive languages, it is difficult to learn and has not found popular favor. Nevertheless, its many unique features make it especially valuable in implementing programs which cannot be easily implemented in other languages (e.g., programs for parallel computations in embedded computers).

By edict, subsets of Ada were forbidden. **Modula-2** was designed to retain the inherent simplicity of PASCAL but include many of the advanced features of Ada. Its advantage lies in implementing large projects involving many programmers. The compilers for this language have rigorous interface cross-checking mechanisms to avoid poor interfaces between components. Another troublesome area is in the implicit use of global data. Modula-2 retains the Ada facilities that allow programmers to share data and avoids incorrectly modifying the data in different program units.

The **C** language was developed by AT&T's Bell Laboratories and subsequently standardized by ANSI. It has a reputation for translating programs into compact and fast code, and for allowing program segments to be precompiled. Its strength rests in the flexibility of the language; for example, it permits statements from other languages to be included in-line in a C program and it offers the largest selection of operators that mirror those available in an assembly language. Because of its flexibility, programs written in C can become unreadable. The C^{++} language was also developed by AT&T Bell Laboratories and standardized by ANSI. The C^{++} language was designed as an extension of C so that the concepts required to design and implement a program would be expressed more directly and concisely. Use of classes to embody the design concept is one of the primary concepts of C^{++}.

Problem-oriented languages have been developed for every discipline. A language might deal with a specialized application within an engineering field, or it might deal with a whole gamut of applications covering one or more fields.

A class of problem-oriented languages that deserves special mention are those for solving problems in **discrete simulation.** GPSS, Simscript, and SIMULA are among the most popular. A simulation (another word for *model*) of a system is used whenever it is desirable to watch a succession of many interrelated events or when there is interplay between the system under study and outside forces. Examples are problems in human-machine interaction and in the modeling of business systems. Typical human-machine problems are the servicing of automatic equipment by a crew of operators (to study crew size and assignments, typically), or responses by shared maintenance crews to equipment subject to unpredictable (random) breakdown. Business models often involve transportation and warehousing studies. A business model could also study the interactions between a business and the rest of the economy such as competitive buying in a raw materials market or competitive marketing of products by manufacturers.

Physical or chemical systems may also be modeled. For example, to study the application of automatic control values in pipelines, the computer model consists of the control system, the valves, the piping system, and the fluid properties. Such a model, when tested, can indicate whether fluid hammer will occur or whether valve action is fast enough. It can also be used to predict pressure and temperature conditions in the fluid when subject to the valve actions.

Another class of problem-oriented languages makes the computer directly accessible to the specialist with little additional training. This is achieved by permitting the user to describe problems to the computer *in terms that are familiar in the discipline of the problem* and for which the language is designed. Two approaches are used. Figures 2.2.9 and 2.2.10 illustrate these.

One approach sets up the computer program directly from the mathematical equations. In fact, problems were formulated in this manner in the past, where analog computers were especially well-suited. Anyone familiar with analog computers finds the transitions to these languages easy. Figure 2.2.9 illustrates this approach using the MIMIC language to write the program for the solution of the initial-value problem:

$$M\ddot{y} + Z\dot{y} + Ky = 1 \qquad \text{and} \qquad \dot{y}(0) = y(0) = 0$$

MIMIC is a digital simulation language used to solve systems of ordinary differential equations. The key step in setting up the solution is to isolate the highest-order derivative on the left-hand side of the equation and equate it to an expression composed of the remaining terms. For the equation above, this results in:

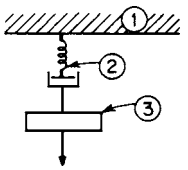
$$\ddot{y} = (1 - Z\dot{y} - Ky)/M$$

The highest-order derivative is derived by equating it to the expression on the right-hand side of the equation. The lower-order derivatives in the expression are generated successively by integrating the highest-order derivative. The MIMIC language permits the user to write these statements in a format closely resembling mathematical notation.

The alternate approach used in problem-oriented languages permits the setup to be described to the computer directly from the block diagram of the physical system. Figure 2.2.10 illustrates this approach using the SCEPTRE language. SCEPTRE statements are written under headings and subheadings which identify the type of component being described. This language may be applied to network problems of electrical digital-logic elements, mechanical-translation or rotational elements, or transfer-function blocks. The translator for this language develops and sets up the equations directly from this description of the

MIMIC statements	Explanation
$DY2 = (1-Z * DY1 - K * Y)/M$	Differential equation to be solved. "*" is used for multiplication and $DY2$, $DY1$, and Y are defined mnemonics for $\ddot{y}$, $\dot{y}$, and y.
$DY1$ = INT($DY2$,0.)	INT (A, B) is used to perform
Y = INT($DY1$,0.)	integration. It forms successive values of $B + \int A dt$.
FIN(T,10.)	T is a reserved name representing the independent variable. This statement will terminate execution when $T \geq 10$.
CON(M, K, Z)	Values must be furnished for M, K, and Z. An input with these values must appear after the END card.
PLO(T,$DY2$)	Three point plots are produced on the
PLO(T,$DY1$)	line printer; $\ddot{y}$, $\dot{y}$, and y vs. t.
PLO(T,Y)	
END	Necessary last statement.

Fig. 2.2.9 Illustration of a MIMIC program.



A node is assigned to:
- ground
- any mass
- point between two elements

The prefix of element name specifies its type, i.e., *M* for mass, *K* for spring, *D* for damper, and *R* for force.

(*a*)

SCEPTRE statements	Explanation
MECHANICAL DESCRIPTION	
ELEMENTS	Specifies the elements and their position in the diagram using the node numbers.
*M*1, 1 − 3 = 10.	
*K*1, 1 − 2 = 40.	
*D*1, 2 − 3 = .5	
*R*1, 1 − 3 = 7.32	
OUTPUT	Results are listed on the line printer.
*SM*1, *VM*1	Prefix on the element specifies the quantity to be listed; *S* for displacement, *V* for velocity.
RUN CONTROL	TIME is reserved name for
STOPTIME = 10.	independent variable. Statement will terminate execution of program when TIME is equal to or greater than 10.
END	Necessary statement.

network diagram, and so relieves the user from the mathematical aspects of the problem.

Application Packages

An application package differs from a language in that its components have been organized to solve problems in a particular application rather than to create the components themselves. The user interacts with the package by initiating the operations and providing the data. From an operational view, packages are built to minimize or simplify interactions with the users by using a menu to initiate operations and entering the data through templets.

Perhaps the most widely used application package is the **word processor.** The objective of a word processor is to allow users to compose text in an electronically stored format which can be corrected or modified, and from which a hard copy can be produced on demand. Besides the basic typewriter operations, it contains functions to manipulate text in blocks or columns, to create headers and footers, to number pages, to find and correct words, to format the data in a variety of ways, to create labels, and to merge blocks of text together. The better word processors have an integrated dictionary, a spelling checker to find and correct misspelled words, a grammar checker to find grammatical errors, and a thesaurus. They often have facilities to prepare complex mathematical equations and to include and manipulate graphical artwork, including editing color pictures. When enough page- and document formatting capability has been added, the programs are known as **desktop publishing** programs.

One of the programs that contributed to the early acceptance of personal computers was the **spread sheet** program. These programs simulate the common spread sheet with its columns and rows of interrelated data. The computerized approach has the advantage that the equations are stored so that the results of a change in data can be shown quickly after any change is made in the data. Modern spread sheet programs have many capabilities, including the ability to obtain information from other spread sheets, to produce a variety of reports, and to prepare equations which have complicated logical aspects.

Tools for **project management** have been organized into commercially available application packages. The objectives of these programs are in the planning, scheduling, and controlling the time-oriented activities describing the projects. There are two basically similar techniques used in these packages. One, called **CPM** (critical path method), assumes that the project activities can be estimated deterministically. The other, called **PERT** (project evaluation and review technology), assumes that the activities can be estimated probabilistically. Both take into account such items as the requirement that certain tasks cannot start before the completion of other tasks. The concepts of **critical path** and **float** are crucial, especially in scheduling the large projects that these programs are used for. In both cases tools are included for estimating project schedules, estimating resources needed and their schedules, and representing the project activities in graphical as well as tabular form.

A major use of the digital computer is in **data reduction,** data analysis, and visualization of data. In installations where large amounts of data are recorded and kept, it is often advisable to reduce the amount of data by ganging the data together, by averaging the data with numerical filters to reduce the amount of noise, or by converting the data to a more appropriate form for storage, analysis, visualization, or future processing. This application has been expanded to produce systems for evaluation, automatic testing, and fault diagnosis by coupling the data acquisition equipment to special peripherals that automatically measure and record the data in a digital format and report the data as meaningful, nonphysically measurable parameters associated with a mathematical model.

Computer-aided design/computer-aided manufacturing **(CAD/CAM)** is an integrated collection of software tools which have been designed to make way for innovative methods of fabricating customized products to meet customer demands. The goal of modern manufacturing is to process orders placed for different products sooner and faster, and to fabricate them without retooling. CAD has the tools for prototyping a design and setting up the factory for production. Working within a framework of agile manufacturing facilities that features automated vehicles, handling robots, assembly robots, and welding and painting robots, the factory sets itself up for production under computer control. Production starts with the receipt of an order on which customers may pick options such as color, size, shapes, and features. Manufacturing proceeds with greater flexibility, quality, and efficiency in producing an increased number of products with a reduced workforce. Effectively, CAD/CAM provides for the ultimate just-in-time (JIT) manufacturing.

Collaboration software is a set of software tools that have been designed to enhance timely and effective communication within a software preparation group. The use of collaboration software has been an important tool to improve the speed and effectiveness of communication for local teams and especially for geographically dispersed teams. With such software, all team members have access to current information such as financial or experimental data, reports, and presentations. Proposals and updates can be provided rapidly to all team members in response to changing conditions. Working within the framework of the collaboration tools can also provide the team with a history that can be very valuable in addressing new problems and in providing new team members with information required to allow them to quickly become effective members of the team.

Two other types of application package illustrate the versatility of data management techniques. One type ties on-line equipment to a computer for collecting real-time data from the production lines. An animated, pictorial display of the production lines forms the heart of the system, allowing supervision in a central control station to continuously track operations. The other type collects time-series data from the various activities in an enterprise. It assists in what is known as **management by exception.** It is especially useful where the detailed data is so voluminous that it is feasible to examine it only in summaries. The data elements are processed and stored in various levels of detail in a seamless fashion. The system stores the reduced data and connects it to the detailed data from which it was derived. The application package allows management, through simple computer operations, to detect a problem at a higher level and to locate and pinpoint its cause through examination of successively lower levels.

PHYSICAL MECHANICS

Definitions

Force is the action of one body on another which will cause acceleration of the second body unless acted on by an equal and opposite action counteracting the effect of the first body. It is a vector quantity.

Time is a measure of the sequence of events. In newtonian mechanics it is an absolute quantity. In relativistic mechanics it is relative to the *frames of reference* in which the sequence of events is observed. The common unit of time is the second.

Inertia is that property of matter which causes a resistance to any change in the motion of a body.

Mass is a quantitative measure of *inertia.*

Acceleration of Gravity Every object which falls in a vacuum at a given position on the earth's surface will have the same acceleration g. Accurate values of the acceleration of gravity as measured *relative* to the earth's surface include the effect of the earth's rotation and flattening at the poles. The international gravity formula for the acceleration of gravity at the earth's surface is $g = 32.0881(1 + 0.005288 \sin^2 \phi - 0.0000059 \sin^2 2\phi)$ ft/s^2, where ϕ is latitude in degrees. For extreme accuracy, the local acceleration of gravity must also be corrected for the presence of large water or land masses and for height above sea level. The absolute acceleration of gravity for a nonrotating earth discounts the effect of the earth's rotation and is rarely used, except outside the earth's atmosphere. If g_0 represents the absolute acceleration at sea level, the absolute value at an altitude h is $g = g_0R^2/(R + h)^2$, where R is the radius of the earth, approximately 3,960 mi (6,373 km).

Weight is the resultant force of attraction on the mass of a body due to a gravitational field. On the earth, units of weight are based upon an acceleration of gravity of 32.1740 ft/s^2 (9.80665 m/s^2).

Linear momentum is the product of mass and the linear velocity of a particle and is a vector. The moment of the linear-momentum vector about a fixed axis is the **angular momentum** of the particle about that fixed axis. For a rigid body rotating about a fixed axis, angular momentum is defined as the product of moment of inertia and angular velocity, each measured about the fixed axis.

An increment of **work** is defined as the product of an incremental displacement and the component of the force vector in the direction of the displacement or the component of the displacement vector in the direction of the force. The increment of work done by a couple acting on a body during a rotation of $d\theta$ in the plane of the couple is $dU = M\,d\theta$.

Energy is defined as the capacity of a body to do work by reason of its motion or configuration (see **Work and Energy**).

A **vector** is a directed line segment that has both magnitude and direction. In script or text, a vector is distinguished from a scalar V by a boldface-type $\mathbf{V}$. The magnitude of the scalar is the magnitude of the vector, $V = |\mathbf{V}|$.

A frame of reference is a specified set of geometric conditions to which other locations, motion, and time are referred. In newtonian mechanics, the fixed stars are referred to as the **primary (inertial) frame of reference.** Relativistic mechanics denies the existence of a primary reference frame and holds that all reference frames must be described relative to each other.

SYSTEMS AND UNITS OF MEASUREMENTS

In *absolute systems*, the units of **length, mass,** and **time** are considered fundamental quantities, and all other units including that of **force** are derived.

In *gravitational systems*, the units of **length, force,** and **time** are considered fundamental qualities, and all other units including that of **mass** are derived.

In the SI system of units, the unit of mass is the kilogram (kg) and the unit of length is the metre (m). A force of one newton (N) is derived as the force that will give 1 kilogram an acceleration of 1 m/s^2.

In the English engineering system of units, the unit of mass is the pound mass (lbm) and the unit of length is the foot (ft). A force of one pound (1 lbf) is the force that gives a pound mass (1 lbm) an acceleration equal to the standard acceleration of gravity on the earth, 32.1740 ft/s^2 (9.80665 m/s^2). A slug is the mass that will be accelerated 1 ft/s^2 by a force of 1 lbf. Therefore, 1 slug = 32.1740 lbm. When described in the gravitational system, mass is a derived unit, being the constant of proportionality between force and acceleration, as determined by Newton's second law.

General Laws

NEWTON'S LAWS

I. If a balanced force system acts on a particle at rest, it will remain at rest. If a balanced force system acts on a particle in motion, it will remain in motion in a straight line without acceleration.

II. If an unbalanced force system acts on a particle, it will accelerate in proportion to the magnitude and in the direction of the resultant force.

III. When two particles exert forces on each other, these forces are equal in magnitude, opposite in direction, and collinear.

Fundamental Equation The basic relation between mass, acceleration, and force is contained in Newton's second law of motion. As applied to a particle of mass, $\mathbf{F} = m\mathbf{a}$, force = mass × acceleration. This equation is a vector equation, since the direction of $\mathbf{F}$ must be the direction of $\mathbf{a}$, as well as having $\mathbf{F}$ equal in magnitude to $m\mathbf{a}$. An alternative form of Newton's second law states that the resultant force is equal to the time rate of change of momentum, $\mathbf{F} = d(m\mathbf{v})/dt$.

Law of the Conservation of Mass The mass of a body remains unchanged by any ordinary physical or chemical change to which it may be subjected. (True in classical mechanics.)

Law of the Conservation of Energy The principle of conservation of energy requires that the total mechanical energy of a system remain unchanged if it is subjected only to forces which depend on position or configuration.

Law of the Conservation of Momentum The linear momentum of a system of bodies is unchanged if there is no resultant external force on the system. The angular momentum of a system of bodies about a fixed axis is unchanged if there is no resultant external moment about this axis.

Law of Mutual Attraction (Gravitation) Two particles attract each other with a force F proportional to their masses m_1 and m_2 and inversely proportional to the square of the distance r between them, or $F = Gm_1m_2/r^2$, in which G is the gravitational constant. The value of the gravitational constant is $G = 6.673 \times 10^{-11}$ m^3/kg · s^2 in SI or absolute units, or $G = 3.44 \times 10^{-8}$ lbf · ft^2/slug^2 in engineering gravitational units. It should be pointed out that the unit of force F in the SI system is the **newton** and is derived, while the unit force in the gravitational system is the **pound-force** and is a fundamental quantity.

EXAMPLE. Each of two solid steel spheres 6 in in diam will weigh 32.0 lb on the earth's surface. This is the force of attraction between the earth and the steel sphere. The force of mutual attraction between the spheres if they are just touching is 0.000000136 lbf. (For spheres, center-to-center distance may be used.)

STATICS OF RIGID BODIES

General Considerations

If the forces acting on a rigid body do not produce any acceleration, they must neutralize each other, i.e., form a **system of forces in equilibrium.** Equilibrium is said to be **stable** when the body with the forces acting upon it returns to its original position after being displaced a very small amount from that position; **unstable** when the body tends to move still farther from its original position than the very small displacement; and **neutral** when the forces retain their equilibrium when the body is in its new position.

External and Internal Forces The forces by which the individual particles of a body act on each other are known as internal forces. All other forces are called external forces. If a body is supported by other bodies while subject to the action of forces, deformations and forces will be produced at the points of support or contact and these internal forces will be distributed throughout the body until equilibrium exists and the body is said to be in a state of tension, compression, or shear. The forces exerted by the body on the supports are known as **reactions.** They are equal in magnitude and opposite in direction to the forces with which the supports act on the body, known as **supporting forces.** The supporting forces are external forces applied to the body.

In considering a body at a definite section, it will be found that all the internal forces act in pairs, the two forces being equal and opposite. The external forces act singly.

General Law When a body is at rest, the forces acting externally to it must form an equilibrium system. This law will hold for any part of the body, in which case the forces acting at any section of the body become external forces when the part on either side of the section is considered alone. In the case of a **rigid body,** any two forces of the same magnitude, but acting in opposite directions in any straight line, may be added or removed without change in the action of the forces acting on the body, provided the strength of the body is not affected.

Composition, Resolution, and Equilibrium of Forces

The **resultant** of several forces acting at a point is a force which will produce the same effect as all the individual forces acting together.

Forces Acting on a Body at the Same Point The resultant R of two forces F_1 and F_2 applied to a rigid body at the same point is represented in magnitude and direction by the diagonal of the parallelogram formed by F_1 and F_2 (see Figs. 3.1.1 and 3.1.2).

$$R = \sqrt{F_1^2 + F_2^2 + 2F_1F_2\cos a}$$

$$\sin a_1 = (F_2 \sin a)/R \qquad \sin a_2 = (F_1 \sin a)/R$$

When $a = 90°$, $R = \sqrt{F_1^2 + F_2^2}$, $\sin a_1 = F_2/R$, and $\sin a_2 = F_1/R$.

When $a = 0°$, $R = F_1 + F_2$
When $a = 180°$, $R = F_1 - F_2$ } Forces act in same straight line.

A **force R may be resolved into two component forces** intersecting anywhere on R and acting in the same plane as R, by the reverse of the operation shown by Figs. 3.1.1 and 3.1.2; and by repeating the operation with the components, R may be resolved into any number of component forces intersecting R at the same point and in the same plane.

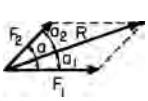

Fig. 3.1.1

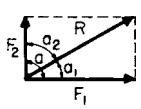

Fig. 3.1.2

Resultant of Any Number of Forces Applied to a Rigid Body at the Same Point Resolve each of the given forces F into components along three rectangular coordinate axes. If A, B, and C are the angles made with XX, YY, and ZZ, respectively, by any force F, the components will be $F \cos A$ along XX, $F \cos B$ along YY, $F \cos C$ along ZZ; add the components of all the forces along each axis algebraically and obtain $\Sigma F \cos A = \Sigma X$ along XX, $\Sigma F \cos B = \Sigma Y$ along YY, and $\Sigma F \cos C = \Sigma Z$ along ZZ.

The resultant $R = \sqrt{(\Sigma X)^2 + (\Sigma Y)^2 + (\Sigma Z)^2}$. The angles made by the resultant with the three axes are A_r with XX, B_r with YY, C_r with ZZ, where

$$\cos A_r = \Sigma X/R \qquad \cos B_r = \Sigma Y/R \qquad \cos C_r = \Sigma Z/R$$

The **direction** of the **resultant** can be determined by plotting the algebraic sums of the components.

If the forces are all in the same plane, the components of each of the forces along one of the three axes (say ZZ) will be 0; i.e., angle $C_r = 90°$ and $R = \sqrt{(\Sigma X)^2 + (\Sigma Y)^2}$, $\cos A_r = \Sigma X/R$, and $\cos B_r = \Sigma Y/R$.

For equilibrium, it is necessary that $R = 0$; i.e., ΣX, ΣY, and ΣZ must each be equal to zero.

General Law In order that a number of forces acting at the same point shall be in equilibrium, the algebraic sum of their components along any *three* coordinate axes must each be equal to zero. When the forces all act in the same plane, the algebraic sum of their components along any *two* coordinate axes must each equal zero.

When the Forces Form a System in Equilibrium Three unknown forces can be determined if the lines of action of the forces are *all* known and are in different planes. If the forces are all in the same plane, the lines of action being known, only *two* unknown forces can be determined. If the lines of action of the unknown forces are *not* known, only *one* unknown force can be determined in either case.

Couples and Moments

Couple Two parallel forces of equal magnitude (Fig. 3.1.3) which act in opposite directions and are not collinear form a couple. **A couple cannot be reduced to a single force.**

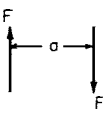

Fig. 3.1.3

Displacement and Change of a Couple The forces forming a couple may be moved about and their magnitude and direction changed, provided they always remain parallel to each other and remain in either the original plane or one parallel to it, and provided the product of one of the forces and the perpendicular distance between the two is constant and the direction of rotation remains the same.

Moment of a Couple The moment of a couple is the product of the magnitude of one of the forces and the perpendicular distance between the lines of action of the forces. Fa = moment of couple; a = arm of couple. If the forces are measured in pounds and the distance a in feet, the **unit of rotation moment** is the foot-pound. If the force is measured in newtons and the distance in metres, the unit is the newton-metre. In the cgs system the unit of rotation moment is 1 cm-dyne.

Rotation moments of couples acting in the same plane are conventionally considered to be positive for counterclockwise moments and negative for clockwise moments, although it is only necessary to be consistent within a given problem. The magnitude, direction, and sense of rotation of a couple are completely determined by its moment axis, or moment vector, which is a line drawn perpendicular to the plane in which the couple acts, with an arrow indicating the direction from which the couple will appear to have right-handed rotation; the length of the line represents the magnitude of the moment of the couple. Figure 3.1.4*a* shows a counterclockwise couple, designated +. Figure 3.1.4*b* shows a clockwise couple, designated −.

T

a single vector (having no specific line of action) perpendicular to the plane of the couple. If you let the relaxed fingers of your right hand represent the "swirl" of the forces in the couple, your stiff right thumb will indicate the direction of the vector. Vector couples may be added vectorially in the same manner by which concurrent forces are added.

Couples lying in the same or parallel planes are added algebraically. Let +28 lbf · ft (+38 N · m), −42 lbf · ft (−57 N · m), and +70 lbf · ft (95 N · m) be the moments of three couples in the same or parallel planes; their resultant is a single couple lying in the same or in a parallel plane, whose moment is $\Sigma M = +28 - 42 + 70 = +56$ lbf · ft ($\Sigma M = +38 - 57 + 95 = 76$ N · m).

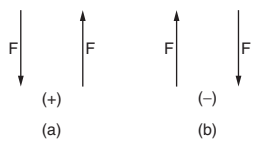

Fig. 3.1.4

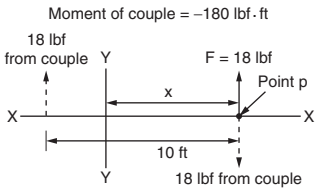

Fig. 3.1.5

If the polygon formed by the moment vectors of several couples closes itself, the couples form an equilibrium system. Two couples will balance each other when they lie in the same or parallel planes and have the same moment in magnitude, but opposite in sign.

Combination of a Couple and a Single Force in the Same Plane (Fig. 3.1.5) Given a force $F = 18$ lbf (80 N) acting as shown at distance x from YY, and a couple whose moment is −180 lbf · ft (244 N · m) in the same or parallel plane, to find the resultant. A couple may be changed to any other couple in the same or a parallel plane having the same moment and same sign. Let the couple consist of two forces of 18 lbf (80 N) each and let the arm be 10 ft (3.05 m). Place the couple in such a manner that one of its forces is opposed to the given force at p. This force of the couple and the given force being of the same magnitude and opposite in direction will neutralize each other, leaving the other force of the couple acting at a distance of 10 ft (3.05 m) from p and parallel and equal to the given force 18 lbf (80 N).

General Rule The resultant of a couple and a single force lying in the same or parallel planes is a single force, equal in magnitude, in the same direction and parallel to the single force, and acting at a distance from the line of action of the single force equal to the moment of the couple divided by the single force. The moment of the resultant force about any point on the line of action of the given single force must be of the same sense as that of the couple, positive if the moment of the couple is positive, and negative if the moment of the couple is negative. If the moment of the couple in Fig. 3.1.5 had been + instead of −, the resultant would have been a force of 18 lbf (80 N) acting in the same direction and parallel to F, but at a distance of 10 ft (3.05 m) to the right of it, making the moment of the resultant about any point on F positive.

To effect a parallel displacement of a single force F over a distance a, a couple whose moment is Fa must be added to the system. The sense of the couple will depend upon which way it is desired to displace force F.

The moment of a force with respect to a point is the product of the force F and the perpendicular distance from the point to the line of action of the force.

The Moment of a Force with Respect to a Straight Line If the force is resolved into components parallel and perpendicular to the given line, the moment of the force with respect to the line is the product of the magnitude of the perpendicular component and the distance from its line of action to the given line.

Forces with Different Points of Application

Composition of Forces If each force **F** is resolved into components parallel to three rectangular coordinate axes XX, YY, ZZ, the magnitude of the resultant is $R = \sqrt{(\Sigma X)^2 + (\Sigma Y)^2 + (\Sigma Z)^2}$, and its line of action makes angles A_r, B_r, and C_r with axes XX, YY, and ZZ, where $\cos A_r = \Sigma X/R$, $\cos B_r = \Sigma Y/R$, and $\cos C_r = \Sigma Z/R$; and there are three couples which may be combined by their moment vectors into a single resultant couple having the moment $M_r = \sqrt{(M_x)^2 + (M_y)^2 + (M_z)^2}$, whose moment vector makes angles of A_m, B_m, and C_m with axes XX, YY, and ZZ, such that $\cos A_m = M_x/M_r$, $\cos B_m = M_y/M_r$, $\cos C_m = M_z/M_r$. If this single resulting couple is in the same plane as the single resulting force at the origin or a plane parallel to it, the system may be reduced to a single force **R** acting at a distance from **R** equal to M_r/R. If the couple and force are not in the same or parallel planes, it is impossible to reduce the system to a single force. If $\mathbf{R} = 0$, i.e., if ΣX, ΣY, and ΣZ all equal zero, the system will reduce to a single couple whose moment is $\mathbf{M}_r$. If $\mathbf{M}_r = 0$, i.e., if M_x, M_y, and M_z all equal zero, the resultant will be a single force **R**.

When the forces are all in the same plane, the cosine of one of the angles A_r, B_r, or $C_r = 0$, say, $C_r = 90°$. Then $R = \sqrt{(\Sigma X)^2 + (\Sigma Y)^2}$, $M_r = \sqrt{M_x^2 + M_y^2}$, and the final resultant is a force equal and parallel to R, acting at a distance from R equal to M_r/R.

A system of forces in the same plane can always be replaced by either a couple or a single force. If $\mathbf{R} = 0$ and $\mathbf{M}_r \cdot 0$, the resultant is a couple. If $\mathbf{M}_r = 0$ and $\mathbf{R} > 0$, the resultant is a single force.

A rigid body is in equilibrium when acted upon by a system of forces whenever $R = 0$ and $M_r = 0$, i.e., when the following six conditions hold true: $\Sigma X = 0$, $\Sigma Y = 0$, $\Sigma Z = 0$, $M_x = 0$, $M_y = 0$, and $M_z = 0$. When the system of forces is in the same plane, equilibrium prevails when the following three conditions hold true: $\Sigma X = 0$, $\Sigma Y = 0$, $\Sigma M = 0$.

Forces Applied to Support Rigid Bodies

The external forces in equilibrium acting upon a body may be statically determinate or indeterminate according to the number of unknown forces existing. When the forces are all in the same plane and act at a common point, two unknown forces may be determined if their lines of action are known, or one unknown force if its line of action is unknown.

When the forces are all in the same plane and are parallel, two unknown forces may be determined if the lines of action are known, or one unknown force if its line of action is unknown.

When the forces are anywhere in the same plane, three unknown forces may be determined if their lines of action are known, if they are not parallel or do not pass through a common point; if the lines of action are unknown, only one unknown force can be determined.

If the forces all act at a common point but are in different planes, three unknown forces can be determined if the lines of action are known, one if unknown.

If the forces act in different planes but are parallel, three unknown forces can be determined if their lines of action are known, one if unknown.

The first step in the solution of problems in statics is the determination of the supporting forces. The following data are required for the complete knowledge of supporting forces: magnitude, direction, and point of application. According to the nature of the problem, none, one, or two of these quantities are known.

One Fixed Support The point of application, direction, and magnitude of the load are known. See Fig. 3.1.6. As the body on which the forces act is in equilibrium, the supporting force P must be equal in magnitude and opposite in direction to the resultant of the loads L.

In the case of a **rolling surface,** the point of application of the support is obtained from the center of the connecting bolt A (Fig. 3.1.7), both the direction and magnitude being unknown. The point of application and

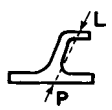

Fig. 3.1.6

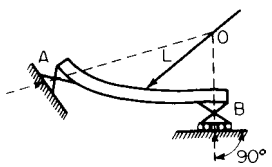

Fig. 3.1.7

line of action of the support at *B* are known, being determined by the rollers.

When three forces acting in the same plane on the same rigid body are in equilibrium, their lines of action must pass through the same point *O*. The load *L* is known in magnitude and direction. The line of action of the support at *B* is known on account of the rollers. The point of application of the support at *A* is known. The three forces are in equilibrium and are in the same plane; therefore, the lines of action must meet at the point *O*.

In the case of the rolling surfaces shown in Fig. 3.1.8, the direction of the support at *A* is known, the magnitude unknown. The line of action and point of application of the supporting force at *B* are known, its

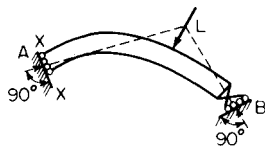

Fig. 3.1.8

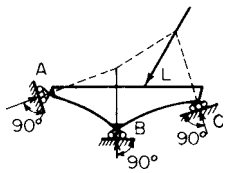

Fig. 3.1.9

magnitude unknown. The lines of action of the three forces must meet in a point, and the supporting force at *A* must be perpendicular to the plane *XX*.

If a member of a truss or frame in equilibrium is pinned at two points and loaded at these two points only, the line of action of the forces exerted on the member or by the member at these two points must be along a line connecting the pins.

If the external forces acting upon a rigid body in equilibrium are all in the same plane, the equations $\Sigma X = 0$, $\Sigma Y = 0$, and $\Sigma M = 0$ must be satisfied. When trusses, frames, and other structures are under discussion, these equations are usually used as $\Sigma V = 0$, $\Sigma H = 0$, $\Sigma M = 0$, where *V* and *H* represent vertical and horizontal components, respectively.

In Fig. 3.1.9, the directions and points of application of the supporting forces are known, but all three are of unknown magnitudes. Including load *L*, there are four forces, and the three unknown magnitudes may be determined by $\Sigma X = 0, \Sigma Y = 0$, and $\Sigma M = 0$.

The **supports** are said to be **statically determinate** when the laws of equilibrium are sufficient for their determination. When the conditions are not sufficient for the determination of the supports or other forces, the structure is said to be **statically indeterminate;** the unknown forces can then be determined from considerations involving the deformation of the material.

When several bodies are so connected to one another as to make up a rigid structure, the forces at the points of connection must be considered as internal forces and are not taken into consideration in the determination of the supporting forces for the structure as a whole.

The distortion of any practically rigid structure under its working loads is so small as to be negligible when determining supporting forces. When the forces acting at the different joints in a built-up structure cannot be determined by dividing the structure up into parts, the structure is said to be **statically indeterminate internally.** A structure may be statically indeterminate internally and still be statically determinate externally.

Fundamental Problems in Graphical Statics

A force may be represented by a straight line in a determined position, and its magnitude by the length of the straight line. The direction in which it acts may be indicated by an arrow.

Polygon of Forces The parallelogram of two forces intersecting each other (see Figs. 3.1.4 and 3.1.5) leads directly to the graphic composition by means of the triangle of forces. In Fig. 3.1.10, *R* is called the **closing side,** and represents the resultant of the forces $\mathbf{F}_1$ and $\mathbf{F}_2$ in magnitude and direction. Its position is given by the point of application *O*. By means of repeated use of the triangle of forces and by omitting the closing sides of the individual triangles, the magnitude and direction of the resultant **R** of any number of forces in the same plane and intersecting

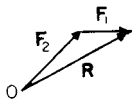

Fig. 3.1.10

at a single point can be found. In Fig. 3.1.11 the lines representing the forces start from point *O*, and in the force polygon (Fig. 3.1.12) they are joined in any order, the arrows showing their directions following around the polygon in the same direction. The magnitude of the resultant at the point of application of the forces is represented by the closing side **R** of the force polygon; its direction, as shown by the arrow, is counter to that in the other sides of the polygon.

If the forces are in equilibrium, R must equal zero, i.e., **the force polygon must close.**

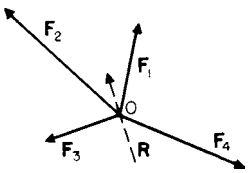

Fig. 3.1.11

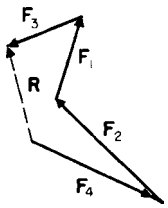

Fig. 3.1.12

If in a closed polygon one of the forces is reversed in direction, this force becomes the resultant of all the others.

Determination of Stresses in Members of a Statically Determinate Plane Structure with Loads at Rest

It will be assumed that the loads are applied at the joints of the structure, i.e., at the points where the different members are connected, and that the connections are pins with no friction. The stresses in the members must then be along lines connecting the pins, unless any member is loaded at more than two points by pin connections.

Equilibrium In order that the whole structure should be in equilibrium, it is necessary that the external forces (loads and supports) shall form a balanced system. Graphical and analytical methods are both of service.

Supporting Forces When the supporting forces are to be determined, it is not necessary to pay any attention to the makeup of the structure under consideration so long as it is practically rigid; the loads may be taken as they occur, or the resultant of the loads may be used instead. When the stresses in the members of the structure are being determined, the loads *must* be distributed at the joints where they belong.

Method of Joints When all the external forces have been determined, any joint at which there are not more than two unknown forces may be taken and these unknown forces determined by the methods of the stress polygon, resolution, or moments. In Fig. 3.1.13, let *O* be the joint of a structure and **F** be the only known force; but let *O*1 and *O*2 be two members of the structure joined at *O*. Then the lines of action of the unknown forces are known and their magnitude may be determined (1) by a **stress polygon** which, for equilibrium, must close; (2) by resolution into *H* and *V* components, using the condition of equilibrium $\Sigma H = 0$, $\Sigma V = 0$; or (3) by moments, using any convenient point on the line of action of *O*1 and *O*2 and the condition of equilibrium $\Sigma M = 0$. No more than *two* unknown forces can be determined. In this manner, proceeding from joint to joint, the stresses in all the members of the truss can usually be determined if the structure is statically determinate internally.

Method of Sections The structure may be divided into parts by passing a section through it cutting some of its members; one part may then be treated as a rigid body and the external forces acting upon it determined. Some of these forces will be the stresses in the members themselves. For example, let *xx* (Fig. 3.1.14) be a section taken through a truss loaded at P_1, P_2, and P_3, and supported on rollers at *S*. As the whole truss is in equilibrium, any part of it must be also, and consequently the part shown to the left of *xx* must be in equilibrium under the action of the forces acting externally to it. Three of these forces are the

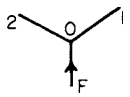

Fig. 3.1.13

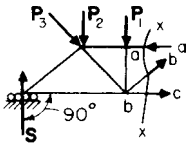

Fig. 3.1.14

stresses in the members *aa*, *bb*, and *bc*, and are the unknown forces to be determined. They can be determined by applying the condition of equilibrium of forces acting in the same plane but not at the same point. $\Sigma H = 0$, $\Sigma V = 0$, $\Sigma M = 0$. The three unknown forces can be determined only if they are not parallel or do not pass through the same point; if, however, the forces are parallel or meet in a point, two unknown forces only can be determined. Sections may be passed through a structure cutting members in any convenient manner, as a rule, however, cutting not more than three members, unless members are unloaded.

For the determination of stresses in framed structures, see Sec. 12.2.

CENTER OF GRAVITY

Consider a three-dimensional body of any size, shape, and weight, but preferably thin and flat. If it is suspended as in Fig. 3.1.15 by a cord from any point *A*, it will be in equilibrium under the action of the tension in the cord and the weight *W*. If the experiment is repeated by suspending the body from point *B*, it will again be in equilibrium. Use a plumb bob through point *A* and draw the "first line" on the body. If the lines of action of the weight were marked in each case, they would be concurrent at a point *G* known as the **center of gravity** or **center of mass.** Whenever the density of the body is uniform, it will be a constant factor and like geometric shapes of different densities will have the same center of gravity. The term **centroid** is used in this case since the location of the center of gravity is of geometric concern only. If densities are nonuniform, like geometric shapes will have the same centroid but different centers of gravity.

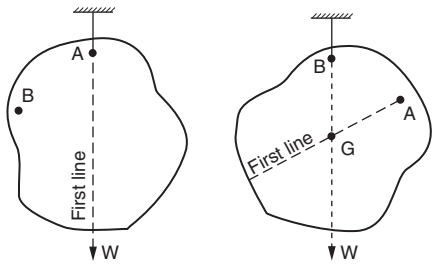

Fig. 3.1.15

Centroids of Technically Important Lines, Areas, and Solids

CENTROIDS OF LINES

Straight Lines The centroid is at its middle point.

Circular Arc *AB* (Fig. 3.1.16) $x_0 = r \sin c/\text{rad } c$; $y_0 = 2r \sin^2 \frac{1}{2}c/\text{rad } c$. (rad c = angle c measured in radians.)

Circular Arc *AC* (Fig. 3.1.17) $x_0 = r \sin c/\text{rad } c$; $y_0 = 0$.

Quadrant, *AB* (Fig. 3.1.18*a*) $x_0 = y_0 = 2r/\pi = 0.6366r$.

Semicircumference, *AC* (Fig. 3.1.18*b*) $y_0 = 2r/\pi = 0.6366r$; $x_0 = 0$.

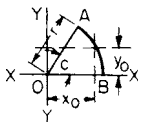

Fig. 3.1.16

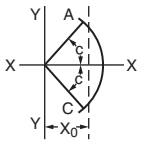

Fig. 3.1.17

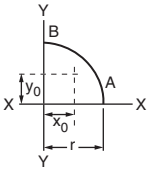

Fig. 3.1.18*a*

Combination of Arcs and Straight Line (Fig. 3.1.19) *AD* and *BC* are two quadrants of radius *r*. $y_0 = \{(AB)r + 2[0.5\pi r(r - 0.6366r)]\} \div [AB + 2(0.5\pi r)]$ (Symmetrical about *YY*).

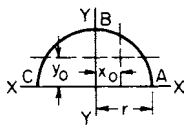

Fig. 3.1.18*b*

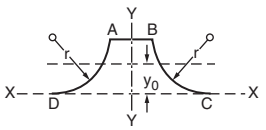

Fig. 3.1.19

CENTROIDS OF PLANE AREAS

Triangle Centroid lies at the intersection of the lines joining the vertices with the midpoints of the sides, and at a distance from any side equal to one-third of the corresponding altitude.

Parallelogram Centroid lies at the point of intersection of the diagonals.

Trapezoid (Fig. 3.1.20) Centroid lies on the line joining the middle points *m* and *n* of the parallel sides. The distances h_a and h_b are

$$h_a = h(a + 2b)/3(a + b) \qquad h_b = h(2a + b)/3(a + b)$$

Draw $BE = a$ and $CF = b$; *EF* will then intersect *mn* at centroid.

Any Quadrilateral The centroid of any quadrilateral may be determined by the general rule for areas, or graphically by dividing it into two sets of triangles by means of the diagonals. Find the centroid of each of the four triangles and connect the centroids of the triangles belonging to the same set. The intersection of these lines will be centroid of area. Thus, in Fig. 3.1.21, *O*, O_1, O_2, and O_3 are, respectively, the centroids of the triangles *ABD*, *ABC*, *BDC*, and *ACD*. The intersection of O_1O_3 with OO_2 gives the centroid of the quadrilateral area.

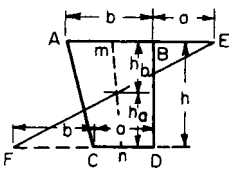

Fig. 3.1.20

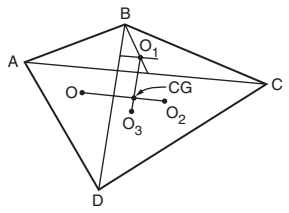

Fig. 3.1.21

Segment of a Circle (Fig. 3.1.22) $x_0 = \frac{2}{3}r \sin^3 c/(\text{rad } c - \cos c \sin c)$. A segment may be considered to be a sector from which a triangle is subtracted, and the general rule applied.

Sector of a Circle (Fig. 3.1.23) $x_0 = \frac{2}{3}r \sin c/\text{rad } c$; $y_0 = \frac{4}{3}r \sin^2 \frac{1}{2}\ c/\text{rad } c$.

Semicircle $x_0 = \frac{4}{3}r/\pi = 0.4244r$; $y_0 = 0$.

Quadrant (90° sector) $x_0 = y_0 = \frac{4}{3}r/\pi = 0.4244r$.

Parabolic Half Segment (Fig. 3.1.24) Area ABO: $x_0 = \frac{3}{5}x_1$; $y_0 = \frac{3}{8}y_1$.
Parabolic Spandrel (Fig. 3.1.24) Area AOC: $x'_0 = \frac{3}{10}x_1$; $y'_0 = \frac{3}{4}y_1$.

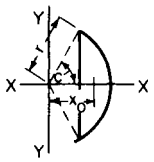

Fig. 3.1.22

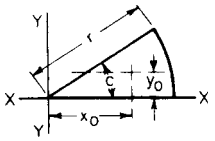

Fig. 3.1.23

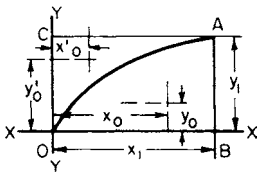

Fig. 3.1.24

Quadrant of an Ellipse (Fig. 3.1.25) Area OAB: $x_0 = \frac{4}{3}(a/\pi)$; $y_0 = \frac{4}{3}(b/\pi)$.

The centroid of a figure such as that shown in Fig. 3.1.26 may be determined as follows: Divide the area $OABC$ into a number of parts by lines drawn perpendicular to the axis XX, e.g., 11, 22, 33, etc. These parts will be approximately either triangles, rectangles, or trapezoids. The area of each division may be obtained by taking the product of its

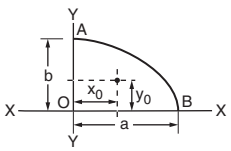

Fig. 3.1.25

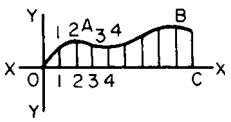

Fig. 3.1.26

mean height and its base. The centroid of each area may be obtained as previously shown. The sum of the moments of all the areas about XX and YY, respectively, divided by the sum of the areas will give approximately the distances from the center of gravity of the whole area to the axes XX and YY. The greater the number of areas taken, the more nearly exact the result.

Centroids of Solids

Prism or Cylinder with Parallel Bases The centroid lies in the center of the line connecting the centers of gravity of the bases.

Oblique Frustum of a Right Circular Cylinder (Fig. 3.1.27) Let 1 2 3 4 be the plane of symmetry. The distance from the base to the centroid is $\frac{1}{2}h + (r^2 \tan^2 c)/8h$, where c is the angle of inclination of the oblique section to the base. The distance of the centroid from the axis of the cylinder is $r^2 \tan c/4h$.

Pyramid or Cone The centroid lies in the line connecting the centroid of the base with the vertex and at a distance of one-fourth of the altitude above the base.

Truncated Pyramid If h is the height of the truncated pyramid and A and B the areas of its bases, the distance of its centroid from the surface of A is

$$h(A + 2\sqrt{AB} + 3B)/4(A + \sqrt{AB} + B)$$

Truncated Circular Cone If h is the height of the frustum and R and r the radii of the bases, the distance from the surface of the base whose radius is R to the centroid is $h(R^2 + 2Rr + 3r^2)/4(R^2 + Rr + r^2)$.

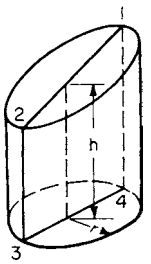

Fig. 3.1.27

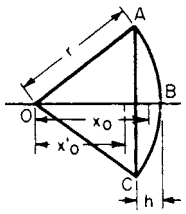

Fig. 3.1.28

Segment of a Sphere (Fig. 3.1.28) Volume ABC: $x_0 = 3(2r - h)^2/4(3r - h)$.

Hemisphere $x_0 = 3r/8$.

Hollow Hemisphere $x_0 = 3(R^4 - r^4)/8(R^3 - r^3)$, where R and r are, respectively, the outer and inner radii.

Sector of a Sphere (Fig. 3.1.28) Volume $OABCO$: $x'_0 = \frac{3}{8}(2r - h)$.

Ellipsoid, with Semiaxes *a, b,* and *c* For each octant, distance from center of gravity to each of the bounding planes $= \frac{3}{8} \times$ length of semiaxis perpendicular to the plane considered.

The formulas given for the determination of the centroid of lines and areas can be used to determine the areas and volumes of surfaces and solids of revolution, respectively, by employing the theorems of Pappus, Sec. 2.1.

Determination of Center of Gravity of a Body by Experiment The center of gravity may be determined by hanging the body up from different points and plumbing down; the point of intersection of the plumb lines will give the center of gravity. It may also be determined as shown in Fig. 3.1.29. The body is placed on knife-edges which rest on platform scales. The sum of the weights registered on the two scales ($w_1 + w_2$) must equal the weight (w) of the body. Taking a moment axis at either end (say, O), $w_2A/w = x_0$ = distance from O to plane containing the center of gravity. (See also Fig. 3.1.15 and accompanying text.)

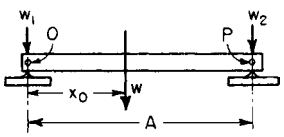

Fig. 3.1.29

Graphical Determination of the Centroids of Plane Areas See Fig. 3.1.40.

MOMENT OF INERTIA

The **moment of inertia of a solid body** with respect to a given axis is the limit of the sum of the products of the masses of each of the elementary particles into which the body may be conceived to be divided and the square of their distance from the given axis.

If $dm = dw/g$ represents the mass of an elementary particle and y its distance from an axis, the moment of inertia I of the body about this axis will be $I = \int y^2\, dm = \int y^2\, dw/g$.

The moment of inertia may be expressed in weight units ($I_w = \int y^2\, dw$), in which case the moment of inertia in weight units, I_w, is equal to the moment of inertia in mass units, I, multiplied by g.

If $I = k^2m$, the quantity k is called the **radius of gyration** or the **radius of inertia.**

If a body is considered to be composed of a number of parts, its moment of inertia about an axis is equal to the sum of the moments of inertia of the several parts about the same axis, or $I = I_1 + I_2 + I_3 + \cdots + I_n$.

The **moment of inertia of an area** with respect to a given axis that lies in the plane of the area is the limit of the sum of the products of the elementary areas into which the area may be conceived to be divided and the square of their distance (y) from the axis in question. $I = \int y^2\, dA = k^2A$, where $k =$ **radius of gyration.**

The quantity $\int y^2\, dA$ is more properly referred to as the *second moment of area* since it is not a measure of *inertia* in a true sense.

Formulas for moments of inertia and radii of gyration of various areas follow later in this section.

Relation between the Moments of Inertia of an Area and a Solid The moment of inertia of a solid of elementary thickness about an axis is equal to the moment of inertia of the area of one face of the solid about the same axis multiplied by the mass per unit volume of the solid times the elementary thickness of the solid.

Moments of Inertia about Parallel Axes The moment of inertia of an area or solid about any given axis is equal to the moment of inertia about a parallel axis through the center of gravity plus the square of the distance between the two axes times the area or mass.

In Fig. 3.1.30*a*, the moment of inertia of the area *ABCD* about axis *YY* is equal to I_0 (or the moment of inertia about Y_0Y_0 through the center of gravity of the area and parallel to *YY*) plus x_0^2A, where $A =$ area of *ABCD*. In Fig. 3.1.30*b*, the moment of inertia of the mass m about $YY = I_0 + x_0^2m$. Y_0Y_0 passes through the centroid of the mass and is parallel to *YY*.

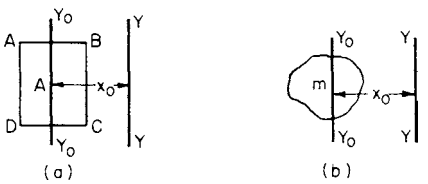

Fig. 3.1.30

Polar Moment of Inertia The polar moment of inertia (Fig. 3.1.31) is taken about an axis perpendicular to the plane of the area. Referring to Fig. 3.1.31, if I_y and I_x are the moments of inertia of the area A about *YY* and *XX*, respectively, then the polar moment of inertia $I_p = I_x + I_y$, or the polar moment of inertia is equal to the sum of the moments of inertia about any two axes at right angles to each other in the plane of the area and intersecting at the pole.

Product of Inertia This quantity will be represented by I_{xy}, and is $\int\int xy\, dy\, dx$, where x and y are the coordinates of any elementary part into which the area may be conceived to be divided. I_{xy} may be positive or negative, depending upon the position of the area with respect to the coordinate axes *XX* and *XY*.

Relation between Moments of Inertia about Axes Inclined to Each Other Referring to Fig. 3.1.32, let I_y and I_x be the moments of inertia of the area A about *YY* and *XX*, respectively, I'_y and I'_x the moments about $Y'Y'$ and $X'X'$, and I_{xy} and I'_{xy} the products of inertia for *XX* and *YY*, and $X'X'$ and $Y'Y'$, respectively. Also, let c be the angle between the respective pairs of axes, as shown. Then,

$$I'_y = I_y \cos^2 c + I_x \sin^2 c + I_{xy} \sin 2c$$

$$I'_x = I_x \cos^2 c + I_y \sin^2 c + I_{xy} \sin 2c$$

$$I'_{xy} = \frac{I_x - I_y}{2} \sin 2c + I_{xy} \cos 2c$$

Principal Moments of Inertia In every plane area, a given point being taken as the origin, there is at least one pair of rectangular axes

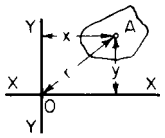

Fig. 3.1.31

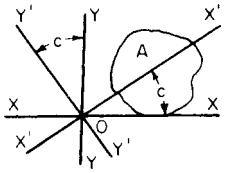

Fig. 3.1.32

in the plane of the area about one of which the moment of inertia is a maximum, and a minimum about the other. These moments of inertia are called the **principal moments of inertia,** and the axes about which they are taken are the **principal axes of inertia.** One of the conditions for principal moments of inertia is that the product of inertia I_{xy} shall equal zero. **Axes of symmetry** of an area are always principal axes of inertia.

Relation between Products of Inertia and Parallel Axes In Fig. 3.1.33, X_0X_0 and Y_0Y_0 pass through the center of gravity of the area parallel to the given axes *XX* and *YY*. If I_{xy} is the product of inertia for *XX* and *YY*, and $I_{x_0y_0}$ that for X_0X_0 and Y_0Y_0, then $I_{xy} = I_{x_0y_0} + abA$.

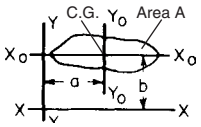

Fig. 3.1.33

Mohr's Circle The **principal moments of inertia** and the location of the **principal axes of inertia** for any point of a plane area may be established graphically as follows.

Given at any point A of a plane area (Fig. 3.1.34), the moments of inertia I_x and I_y about axes X and Y, and the product of inertia I_{xy} relative to X and Y. The graph shown in Fig. 3.1.34*b* is plotted on rectangular coordinates with moments of inertia as abscissas and products of inertia

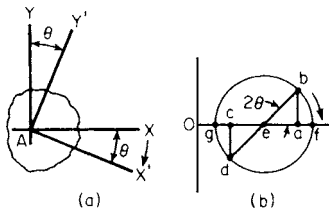

Fig. 3.1.34

as ordinates. Lay out $Oa = I_x$ and $ab = I_{xy}$ (upward for positive products of inertia, downward for negative). Lay out $Oc = I_y$ and $cd =$ *negative of* I_{xy}. Draw a circle with bd as diameter. This is **Mohr's circle.** The *maximum* moment of inertia $I'_x = Of$; the *minimum* moment of inertia is $I'_y = Og$. The principal axes of inertia are located as follows. From axis AX (Fig. 3.1.34*a*) lay out angular distance $\theta = \frac{1}{2} < bef$. This locates axis AX', one principal axis ($I'_x = Of$). The other principal axis of inertia is AY', perpendicular to AX' ($I'_x = Og$).

The **moment of inertia of any area** may be considered to be made up of the sum or difference of the known moments of inertia of simple figures. For example, the dimensioned figure shown in Fig. 3.1.35 represents the section of a rolled shape with hole *oprs* and may be divided

into the semicircle *abc*, rectangle *edkg*, and triangles *mfg* and *hkl*, from which the rectangle *oprs* is to be subtracted. Referring to axis *XX*,

$$I_{xx} = \pi 4^4/8 \text{ for semicircle } abc + (2 \times 11^3)/3 \text{ for rectangle } edkg + 2[(5 \times 3^3)/36 + 10^2(5 \times 3)/2] \text{ for the two triangles } mfg \text{ and } hkl$$

From the sum of these there is to be subtracted $I_{xx} = [(2 \times 3^2)/12 + 4^2(2 \times 3)]$ for the rectangle *oprs*.

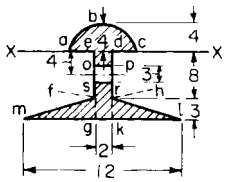

Fig. 3.1.35

If the moment of inertia of the whole area is required about an axis parallel to *XX*, but passing through the center of gravity of the whole area, $I_0 = I_{xx} - x_0^2 A$, where x_0 = distance from *XX* to center of gravity. The **moments of inertia of built-up sections** used in structural work may be found in the same manner, the moments of inertia of the different **rolled sections** being given in Sec. 12.2.

Moments of Inertia of Solids For moments of inertia of solids about parallel axes, $I_x = I_0 + x_0^2 m$.

Moment of Inertia with Reference to Any Axis Let a mass particle *dm* of a body have *x*, *y*, and *z* as coordinates, *XX*, *YY*, and *ZZ* being the coordinate axes and *O* the origin. Let *X′X′* be any axis passing through the origin and making angles of *A*, *B*, and *C* with *XX*, *YY*, and *ZZ*, respectively. The moment of inertia with respect to this axis then becomes equal to

$$I'_x = \cos^2 A \int (y^2 + z^2)\, dm + \cos^2 B \int (z^2 \times x^2)\, dm + \cos^2 C \int (x^2 + y^2)\, dm - 2 \cos B \cos C \int yz\, dm - 2 \cos C \cos A \int zx\, dm - 2 \cos A \cos B \int xy\, dm$$

Let the moment of inertia about $XX = I_x = \int (y^2 + z^2)\, dm$, about $YY = I_y = \int (z^2 + x^2)\, dm$, and about $ZZ = I_z = \int (x^2 + y^2)\, dm$. Let the products of inertia about the three coordinate axes be

$$I_{yz} = \int yz\, dm \qquad I_{zx} = \int zx\, dm \qquad I_{xy} = \int xy\, dm$$

Then the moment of inertia I'_x becomes equal to

$$I_x \cos^2 A + I_y \cos^2 B + I_z \cos^2 C - 2I_{yz} \cos B \cos C - 2I_{zx} \cos C \cos A - 2I_{xy} \cos A \cos B$$

The moment of inertia of any solid may be considered to be made up of the sum or difference of the moments of inertia of simple solids of which the moments of inertia are known.

Moments of Inertia of Important Solids (Homogeneous)

w = weight per unit of volume of the body
$m = w/g$ = mass per unit of volume of the body
$M = W/g$ = total mass of body
r = radius
I = moment of inertia (mass units)
$I_w = I \times g$ = moment of inertia (weight units)

Solid circular cylinder about its axis: $I = \pi r^4 ma/2 = Mr^2/2$. ($a$ = length of axis of cylinder.)

Solid circular cylinder about an axis through the center of gravity and perpendicular to axis of cylinder: $I = M[r^2 + (a^2/3)]/4$.

Hollow circular cylinder about its axis: $I = M(r_1^2 + r_2^2)/2$ (r_1 and r_2 = outer and inner radii).

Thin-walled hollow circular cylinder about its axis: $I = Mr^2$.

Solid sphere about a diameter: $I = 8m\pi r^5/15 = 2Mr^2/5$.

Thin hollow sphere about a diameter: $I = 2Mr^2/3$.

Thick hollow sphere about a diameter: $I = 8m\pi(r_1^5 - r_2^5)/15$. ($r_1$ and r_2 are outer and inner radii.)

Rectangular prism about an axis through center of gravity and perpendicular to a face whose dimensions are a and b: $I = M(a^2 + b^2)/12$.

Solid right circular cone about an axis through its apex and perpendicular to its axis: $I = 3M[(r^2/4) + h^2]/5$. (h = altitude of cone, r = radius of base.)

Solid right circular cone about its axis of revolution: $I = 3Mr^2/10$.

Ellipsoid with semiaxes a, b, and c: I about diameter $2c$ (z axis) = $4m\pi abc\,(a^2 + b^2)/15$. [Equation of ellipsoid: $(x^2/a^2) + (y^2/b^2) + (z^2/c^2) = 1$.]

Ring with Circular Section (Fig. 3.1.36) $I_{yy} = \frac{1}{2}m\pi^2 Ra^2(4R^2 + 3a^2)$; $I_{xx} = m\pi^2 Ra^2[R^2 + (5a^2/4)]$.

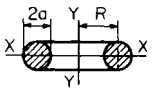

Fig. 3.1.36

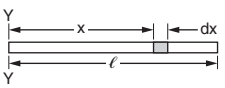

Fig. 3.1.37

Approximate Moments of Inertia of Solids In order to determine the moment of inertia of a solid, it is necessary to know all its dimensions. In the case of a rod of mass M (Fig. 3.1.37) and length l, with shape and size of the cross section unknown, making the approximation that the weight is all concentrated along the axis of the rod, the moment of inertia about *YY* will be $I_{yy} = \int_0^l (M/l)x^2\, dx = Ml^2/3$

A **thin plate** may be treated in the same way (Fig. 3.1.38): $I_{yy} = \int_0^l (M/l)x^2\, dx = \frac{1}{3}Ml^2$.

Thin Ring, or Cylinder (Fig. 3.1.39) Assume the mass M of the ring or cylinder to be concentrated at a distance r from *O*. The moment of inertia about an axis through *O* perpendicular to plane of ring or along the axis of the cylinder will be $I = Mr^2$; this will be greater than the exact moment of inertia, and r is sometimes taken as the distance from *O* to the center of gravity of the cross section of the rim.

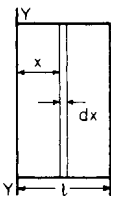

Fig. 3.1.38

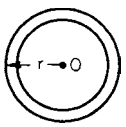

Fig. 3.1.39

Flywheel Effect The moment of inertia of a solid is often called flywheel effect in the solution of problems dealing with rotating bodies.

Graphical Determination of the Centroids and Moments of Inertia of Plane Areas Required to find the center of gravity of the area *MNP* (Fig. 3.1.40) and its moment of inertia about any axis *XX*.

Draw any line *SS* parallel to *XX* and at a distance *d* from it. Draw a number of lines such as *AB* and *EF* across the figure parallel to *XX*. From *E* and *F* draw *ER* and *FT* perpendicular to *SS*. Select as a pole any

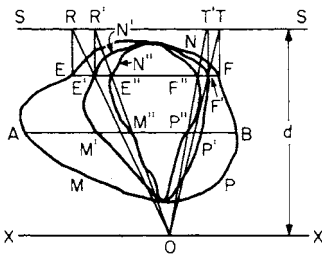

Fig. 3.1.40

point on *XX*, preferably the point nearest the area, and draw *OR* and *OT*, cutting *EF* at *E′* and *F′*. If the same construction is repeated, using other lines parallel to *XX*, a number of points will be obtained, which, if connected by a smooth curve, will give the area *M′N′P′*. Project *E′* and *F′* onto *SS* by lines *E′R′* and *F′T′*. Join *F′* and *T′* with *O*, obtaining *E″* and *F″*; connect the points obtained using other lines parallel to *XX* and obtain an area *M″N″P″*. The area *M′N′P′* × *d* = moment of area *MNP* about the line *XX*, and the distance from *XX* to the centroid *MNP* = area *M′N′P′* × *d*/area *MNP*. Also, area *M″N″P″* × d^2 = moment of inertia of *MNP* about *XX*. The areas *M′N′P′* and *M″N″P″* can best be obtained by use of a planimeter.

KINEMATICS

Kinematics is the study of the motion of bodies without reference to the forces causing that motion or the mass of the bodies.

The **displacement** of a point is the directed distance that a point has moved on a geometric path from a convenient origin. It is a **vector,** having both magnitude and direction, and is subject to all the laws and characteristics attributed to vectors. In Fig. 3.1.41, the displacement of the point *A* from the origin *O* is the directed distance *O* to *A*, symbolized by the vector **s**.

The **velocity** of a point is the time rate of change of displacement, or $\mathbf{v} = d\mathbf{s}/dt$.

The **acceleration** of a point is the time rate of change of velocity, or $\mathbf{a} = d\mathbf{v}/dt$.

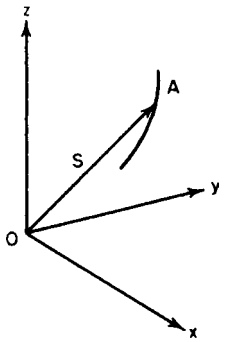

Fig. 3.1.41

The kinematic definitions of velocity and acceleration involve the four variables, *displacement, velocity, acceleration,* and *time.* If we eliminate the variable of time, a third equation of motion is obtained, $ds/v = dt = dv/a$. This differential equation, together with the definitions of velocity and acceleration, make up the *three kinematic equations* of motion, $v = ds/dt$, $a = dv/dt$, and $a\,ds = v\,dv$. These differential equations are usually limited to the scalar form when expressed together, since the last can only be properly expressed in terms of the scalar *dt*. The first two, since they are definitions for velocity and acceleration, are **vector equations.**

A **space-time curve** offers a convenient means for the study of the motion of a point that moves in a straight line. The **slope of the curve** at any point will represent the **velocity** at that time. In Fig. 3.1.42*a* the slope is constant, as the graph is a straight line; the velocity is therefore uniform. In Fig. 3.1.42*b* the slope of the curve varies from point to point, and the velocity must also vary. At *p* and *q* the slope is zero; therefore, the velocity of the point at the corresponding times must also be zero.

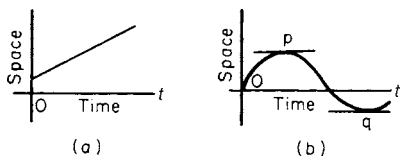

Fig. 3.1.42

A **velocity-time curve** offers a convenient means for the study of acceleration. The **slope of the curve** at any point will represent the **acceleration** at that time. In Fig. 3.1.43*a* the slope is constant; so the acceleration must be constant. In the case represented by the full line, the acceleration is positive; so the velocity is increasing. The dotted line shows a negative acceleration and therefore a decreasing velocity. In Fig. 3.1.43*b* the slope of the curve varies from point to point; so the acceleration must also vary. At *p* and *q* the slope is zero; therefore, the acceleration of the point at the corresponding times must also be zero. The area under the velocity-time curve between any two ordinates such as *NL* and *HT* will represent the distance moved in time interval *LT*. In the case of the uniformly accelerated motion shown by the full line in Fig. 3.1.43*a*, the area *LNHT* is ½(*NL* + *HT*) × (*OT* − *OL*) = mean velocity multiplied by the time interval = space passed over during this time interval. In Fig. 3.1.43*b* the mean velocity can be obtained from the equation of the curve by means of the calculus, or graphically by approximation of the area.

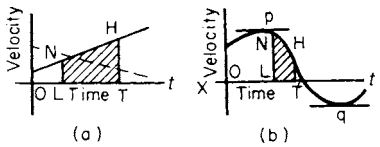

Fig. 3.1.43

An **acceleration-time curve** (Fig. 3.1.44) may be constructed by plotting accelerations as ordinates, and times as abscissas. The area under this curve between any two ordinates will represent the total increase in velocity during the time interval. The area *ABCD* represents the total increase in velocity between time t_1 and time t_2.

General Expressions Showing the Relations between Space, Time, Velocity, and Acceleration for Rectilinear Motion

SPECIAL MOTIONS

Uniform Motion If the **velocity** is **constant,** the **acceleration** must be **zero,** and the point has uniform motion. The space-time curve becomes a straight line inclined toward the time axis (Fig. 3.1.42*a*). The velocity-time curve becomes a straight line parallel to the time axis. For this motion $a = 0$, v = constant, and $s = s_0 + vt$.

Uniformly Accelerated or Retarded Motion If the **velocity** is **not uniform** but the **acceleration** is **constant,** the point has uniformly accelerated motion; the acceleration may be either positive or negative. The space-time curve becomes a parabola and the velocity-time curve becomes a straight line inclined toward the time axis (Fig. 3.1.43*a*). The acceleration-time curve becomes a straight line parallel to the time axis. For this motion a = constant, $v = v_0 + at$, $s = s_0 + v_0t + \frac{1}{2}at^2$.

If the point starts from rest, $v_0 = 0$. Care should be taken concerning the sign + or − for acceleration.

Composition and Resolution of Velocities and Acceleration

Resultant Velocity A velocity is said to be the resultant of two other velocities when it is represented by a vector that is the geometric sum of the vectors representing the other two velocities. This is the **parallelogram of motion.** In Fig. 3.1.45, **v** is the resultant of $\mathbf{v}_1$ and $\mathbf{v}_2$

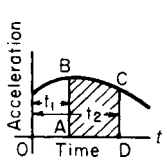

Fig. 3.1.44

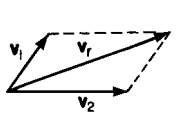

Fig. 3.1.45

and is represented by the diagonal of a parallelogram of which $\mathbf{v}_1$ and $\mathbf{v}_2$ are the sides; or it is the third side of a triangle of which $\mathbf{v}_1$ and $\mathbf{v}_2$ are the other two sides.

Polygon of Motion The parallelogram of motion may be extended to the polygon of motion. Let $\mathbf{v}_1$, $\mathbf{v}_2$, $\mathbf{v}_3$, $\mathbf{v}_4$ (Fig. 3.1.46*a*) show the directions of four velocities imparted in the same plane to point *O*. If the lines $\mathbf{v}_1$, $\mathbf{v}_2$, $\mathbf{v}_3$, $\mathbf{v}_4$ (Fig. 3.1.46*b*) are drawn parallel to and proportional to the velocities imparted to point *O*, $\mathbf{v}$ will represent the resultant velocity imparted to *O*. It will make no difference in what order the velocities are taken in constructing the motion polygon. As long as the arrows showing the direction of the motion follow each other in order about the polygon, the resultant velocity of the point will be represented in magnitude by the closing side of the polygon, but opposite in direction.

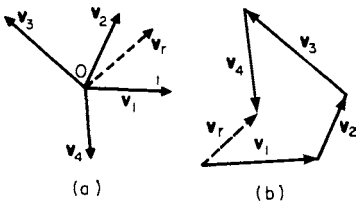

Fig. 3.1.46

Resolution of Velocities Velocities may be resolved into **component velocities** in the same plane, as shown by Fig. 3.1.47. Let the velocity of point *O* be v_r. In Fig. 3.1.47*a* this velocity is resolved into two components in the same plane as v_r and at right angles to each other.

$$v_r = \sqrt{(v_1)^2 + (v_2)^2}$$

In Fig. 3.1.47*b* the components are in the same plane as v_r, but are not at right angles to each other. In this case,

$$v_r = \sqrt{(v_1)^2 + (v_2)^2 + 2v_1v_2\cos B}$$

If the components v_1 and v_2 and angle B are known, the direction of v_r can be determined. $\sin bOc = (v_1/v_r)\sin B$. $\sin cOa = (v_2/v_r)\sin B$. Where v_1 and v_2 are at right angles to each other, $\sin B = 1$.

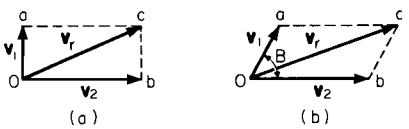

Fig. 3.1.47

Resultant Acceleration Accelerations may be combined and resolved in the same manner as velocities, but in this case the lines or vectors represent accelerations instead of velocities. If the acceleration had components of magnitude a_1 and a_2, the magnitude of the resultant acceleration would be $a = \sqrt{(a_1)^2 + (a_2)^2 + 2a_1a_2\cos B}$, where B is the angle between the vectors $\mathbf{a}_1$ and $\mathbf{a}_2$.

Curvilinear Motion in a Plane

The linear velocity $v = ds/dt$ of a point in curvilinear motion is the same as for rectilinear motion. Its direction is tangent to the path of the point. In Fig. 3.1.48*a*, let $P_1P_2P_3$ be the path of a moving point and $\mathbf{V}_1$, $\mathbf{V}_2$, $\mathbf{V}_3$ represent its velocity at points P_1, P_2, P_3, respectively. If *O* is taken as a pole (Fig. 3.1.48*b*) and vectors $\mathbf{V}_1$, $\mathbf{V}_2$, $\mathbf{V}_3$ representing the velocities of the point at P_1, P_2, and P_3 are drawn, the curve connecting the terminal points of these vectors is known as the **hodograph** of the motion. This velocity diagram is applicable only to motions all in the same plane.

Acceleration Tangents to the curve (Fig. 3.1.48*b*) indicate the directions of the **instantaneous velocities.** The direction of the tangents does not, as a rule, coincide with the direction of the accelerations as represented by tangents to the path. If the acceleration a at some point in the path is resolved by means of a parallelogram into components tangent and normal to the path, the normal acceleration $a_n = v^2/\rho$, where ρ = radius of curvature of the path at the point in question, and the tangential acceleration $a_t = dv/dt$, where v = velocity tangent to the path at the same point. $a = \sqrt{a_n^2 + a_t^2}$. The normal acceleration is constantly directed toward the concave side of the path.

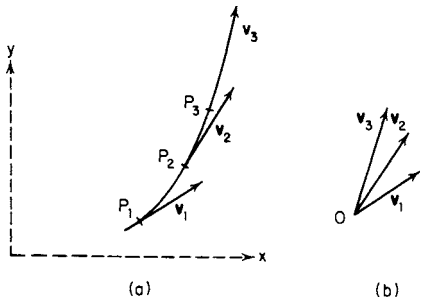

Fig. 3.1.48

EXAMPLE. Figure 3.1.49 shows a point moving in a curvilinear path. At p_1 the velocity is $\mathbf{v}_1$; at p_2 the velocity is $\mathbf{v}_2$. If these velocities are drawn from pole *O* (Fig. 3.1.49*b*), $\Delta\mathbf{v}$ will be the difference between $\mathbf{v}_2$ and $\mathbf{v}_1$. The acceleration during travel p_1p_2 will be $\Delta\mathbf{v}/\Delta t$, where Δt is the time interval. The approximation becomes closer to instantaneous acceleration as shorter intervals Δt are employed.

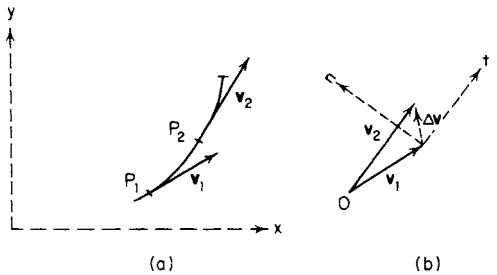

Fig. 3.1.49

The acceleration $\Delta\mathbf{v}/\Delta t$ can be resolved into normal and tangential components leading to $\mathbf{a}_n = \Delta\mathbf{v}_n/\Delta t$, normal to the path, and $\mathbf{a}_t = \Delta\mathbf{v}_t/\Delta t$, tangential to the path.

Velocity and *acceleration* may be expressed in **polar coordinates** such that $v = \sqrt{v_r^2 + v_\theta^2}$ and $a = \sqrt{a_r^2 + a_\theta^2}$. Figure 3.1.50 may be used to explain the r and θ coordinates.

EXAMPLE. At P_1 the velocity is $\mathbf{v}_1$, with components $\mathbf{v}_{1r}$ in the r direction and $\mathbf{v}_{1\theta}$ in the θ direction. At P_2 the velocity is $\mathbf{v}_2$, with components $\mathbf{v}_{2r}$ in the r direction and $\mathbf{v}_{2\theta}$ in the θ direction. It is evident that the difference in velocities $\mathbf{v}_2 - \mathbf{v}_1 = \Delta\mathbf{v}$ will have components $\Delta\mathbf{v}_r$ and $\Delta\mathbf{v}_\theta$, giving rise to accelerations $\mathbf{a}_r$ and $\mathbf{a}_\theta$ in a time interval Δt.

In polar coordinates, $v_r = dr/dt$, $a_r = d^2r/dt^2 - r(d\theta/dt)^2$, $v_\theta = r(d\theta/dt)$, and $a_\theta = r(d^2\theta/dt^2) + 2(dr/dt)(d\theta/dt)$.

If a point P moves on a circular path of radius r with an angular velocity of ω and an angular acceleration of α, the linear velocity of the point P is $v = \omega r$ and the two components of the linear acceleration are $a_n = v^2/r = \omega^2 r = v\omega$ and $a_t = \alpha r$.

If the angular velocity is constant, the point P travels equal circular paths in equal intervals of time. The projected displacement, velocity, and acceleration of the point P on the x and y axes are sinusoidal functions of time, and the motion is said to be **harmonic motion.** Angular velocity is usually expressed in radians per second, and when the number (N) of revolutions traversed per minute (N/min) by the point P is known, the angular velocity of the radius r is $\omega = 2\pi N/60 = 0.10472N$.

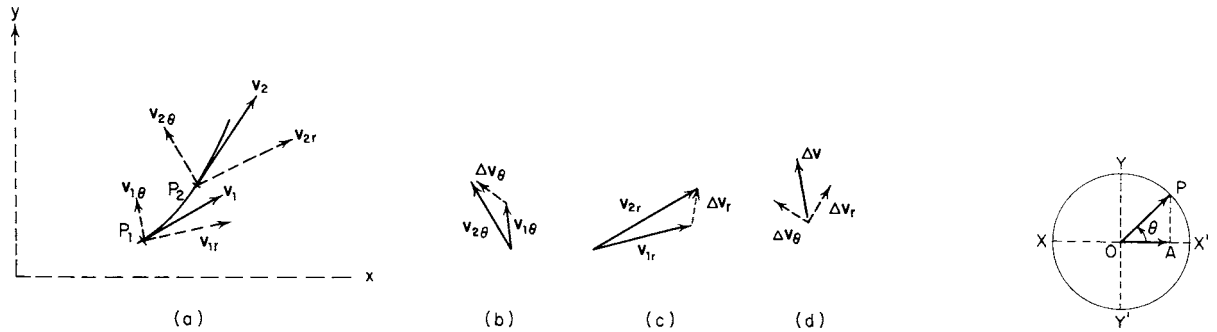

Fig. 3.1.50

Fig. 3.1.51

In Fig. 3.1.51, let the angular velocity of the line OP be a constant ω. Let the point P start at X' and move to P in time t. Then the angle $\theta = \omega t$. If $OP = r$, $OA = s = r \cos \omega t$. The velocity v of the point A on the x axis will equal $ds/dt = -\omega r \sin \omega t$, and the acceleration $a = dv/dt = -\omega^2 r \cos \omega t$. The period τ is the time necessary for the point P to complete one cycle of motion $\tau = 2\pi/\omega$, and it is also equal to the time necessary for A to complete a full cycle on the x axis from X' to X and return.

Curvilinear Motion in Space

If **three dimensions** are used, velocities and accelerations may be resolved into components not in the same plane by what is known as the **parallelepiped of motion.** Three coordinate systems are widely used, cartesian, cylindrical, and spherical. In **cartesian coordinates,** $v = \sqrt{v_x^2 + v_y^2 + v_z^2}$ and $a = \sqrt{a_x^2 + a_y^2 + a_z^2}$. In **cylindrical coordinates,** the radius vector **R** of displacement lies in the rz plane, which is at an angle with the xz plane. Referring to (*a*) of Fig. 3.1.52, the θ coordinate is perpendicular to the rz plane. In this system $v = \sqrt{v_r^2 + v_\theta^2 + v_z^2}$ and $a = \sqrt{a_r^2 + a_\theta^2 + a_z^2}$ where $v_r = dr/dt$, $a_r = d^2r/dt^2 - r(d\theta/dt)^2$, $v_\theta = r(d\theta/dt)$, and $a_\theta = r(d^2\theta/dt^2) + 2(dr/dt)(d\theta/dt)$. In **spherical coordinates,** the three coordinates are the R coordinate, the θ coordinate, and the ϕ coordinate as in (*b*) of Fig. 3.1.52. The velocity and acceleration are $v = \sqrt{v_R^2 + v_\theta^2 + v_\phi^2}$ and $a = \sqrt{a_R^2 + a_\theta^2 + a_\phi^2}$, where $v_R = dR/dt$, $v_\phi = R(d\phi/dt)$, $v_\theta = R \cos \phi(d\theta/dt)$, $a_R = d^2R/dt^2 - R(d\phi/dt)^2 - R \cos^2 \phi(d\theta/dt)^2$, $a_\phi = R(d^2\phi/dt^2) + R \cos \phi \sin \phi\ (d\theta/dt)^2 + 2(dR/dt)(d\phi/dt)$, and $a_\theta = R \cos \phi\ (d^2\theta/dt^2) + 2[(dR/dt) \cos \phi - R \sin \phi\ (d\phi/dt)]\ d\theta/dt$.

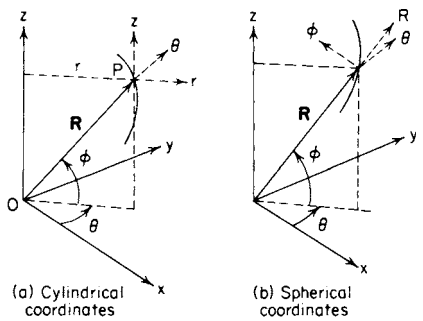

Fig. 3.1.52

Motion of Rigid Bodies

A body is said to be **rigid** when the distances between all its particles are invariable. Theoretically, rigid bodies do not exist, but materials used in engineering are rigid under most practical working conditions. The motion of a rigid body can be completely described by knowing the **angular motion** of a line on the rigid body and the **linear motion** of a point on this line and relating the motion of all other parts of the rigid body to these motions. If a rigid body moves so that a straight line connecting any two of its particles remains parallel to its original position at all times, it is said to have **translation.** In **rectilinear translation,** all points move in straight lines. In **curvilinear translation,** all points move on congruent curves but without rotation. **Rotation** is defined as angular motion about an axis, which may or may not be fixed. Rigid body motion in which the paths of all particles lie on parallel planes is called **plane motion.**

Angular Motion

Angular displacement is the change in angular position of a given line as measured from a convenient reference line. In Fig. 3.1.53, consider the motion of the line AB as it moves from its original position $A'B'$. The angle between lines AB and $A'B'$ is the angular displacement of line **AB,** symbolized as θ. It is a directed quantity and is a vector. The usual notation used to designate angular displacement is a vector normal to

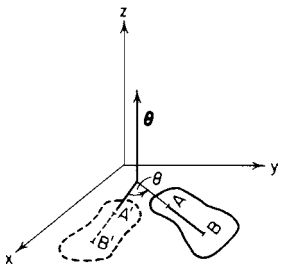

Fig. 3.1.53

the plane in which the angular displacement occurs. The length of the vector is proportional to the magnitude of the angular displacement. For a rigid body moving in three dimensions, the line AB may have angular motion about any three orthogonal axes. For example, the angular displacement can be described in cartesian coordinates as $\theta = \theta_x + \theta_y + \theta_z$, where $\theta = \sqrt{\theta_x^2 + \theta_y^2 + \theta_z^2}$.

Angular velocity is defined as the time rate of change of angular displacement, $\omega = d\theta/dt$. Angular velocity may also have components about any three orthogonal axes.

Angular acceleration is defined as the time rate of change of angular velocity, $\alpha = d\omega/dt = d^2\theta\, dt^2$. Angular acceleration may also have components about any three orthogonal axes.

The *kinematic equations* of angular motion of a line are analogous to those for the motion of a point. In referring to Table 3.1.1, $\omega = d\theta/dt$ $\alpha = d\omega/dt$, and $\alpha\ d\theta = \omega\ d\omega$. Substitute θ for s, ω for v, and α for a.

Motion of a Rigid Body in a Plane

Plane motion is the motion of a rigid body such that the paths of all particles of that rigid body lie on parallel planes.

Table 3.1.1

Variables	$s = f(t)$	$v = f(t)$	$a_2 = f(t)$	$a = f(s, v)$
Displacement		$s = s_0 + \int_{t_0}^{t} v\,dt$	$s = s_0 + \int_{t_0}^{t}\int_{t_0}^{t} a\,dt\,dt$	$s = s_0 + \int_{v_0}^{v} (v/a)\,dv$
Velocity	$v = ds/dt$		$v = v_0 + \int_{t_0}^{t} a\,dt$	$\int_{v_0}^{v} v\,dv = \int_{s_0}^{s} a\,ds$
Acceleration	$a = d^2s/dt^2$	$a = dv/dt$		$a = v\,dv/ds$

Instantaneous Axis When the axis about which any body may be considered to rotate changes its position, any one position is known as an instantaneous axis, and the line through all positions of the instantaneous axis as the **centrode.**

When the velocity of two points in the same plane of a rigid body having plane motion is known, the instantaneous axis for the body will be at the intersection of the lines drawn from each point and perpendicular to its velocity. See Fig. 3.1.54, in which A and B are two points on the rod AB, $\mathbf{v}_1$ and $\mathbf{v}_2$ representing their velocities. O is the instantaneous axis for AB; therefore point C will have velocity shown in a line perpendicular to OC.

Linear velocities of points in a body rotating about an instantaneous axis are proportional to their distances from this axis. In Fig. 3.1.54, $\mathbf{v}_1 : \mathbf{v}_2 : \mathbf{v}_3 = AO : OB : OC$. If the velocities of A and B were parallel, the lines OA and OB would also be parallel and there would be no instantaneous axis. The motion of the rod would be translation, and all points would be moving with the same velocity in parallel straight lines.

If a body has plane motion, the components of the velocities of any two points in the body along the straight line joining them must be equal. Ax must be equal to By and Cz in Fig. 3.1.54.

EXAMPLE. In Fig. 3.1.55*a*, the velocities of points A and B are known—they are $\mathbf{v}_1$ and $\mathbf{v}_2$, respectively. To find the instantaneous axis of the body, perpendiculars AO and BO are drawn. O, at the intersection of the perpendiculars, is the **instantaneous axis** of the body. To find the velocity of any other point, like C, line OC is drawn and v_3 erected perpendicular to OC with magnitude equal to v_1 (CO/AO). The **angular velocity** of the body will be $\omega = v_1/AO$ or v_2/BO or v_3/CO. The instantaneous axis of a wheel rolling on a rack without slipping (Fig. 3.1.55*b*) lies at the point of contact O, which has zero linear velocity. All points of the wheel will have velocities perpendicular to radii to O and proportional in magnitudes to their respective distances from O.

Another way to describe the plane motion of a rigid body is with the use of **relative motion.** In Fig. 3.1.56 the velocity of point A is $\mathbf{v}_1$. The angular velocity of the line AB is ω_{AB}. The velocity of B relative to A is $\omega_{AB} \times r_{AB}$. Point B is considered to be moving on a circular path around A as a center. The direction of relative velocity of B to A would be tangent to the circular path in the direction that ω_{AB} would make B move. The velocity of B is the vector sum of the velocity A added to the velocity of B relative to A, $\mathbf{v}_B = \mathbf{v}_A + \mathbf{v}_{B/A}$.

The **acceleration** of B is the vector sum of the acceleration of A added to the acceleration of B relative to A, $\mathbf{a}_B = \mathbf{a}_A + \mathbf{a}_{B/A}$. Care must be taken to include the complete relative acceleration of B to A. If B is considered to move on a circular path about A, with a velocity relative to A, it will have an acceleration relative to A that has both normal and tangential components: $\mathbf{a}_{B/A} = (\mathbf{a}_{B/A})_n + (\mathbf{a}_{B/A})_t$.

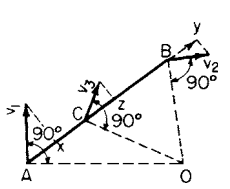

Fig. 3.1.54

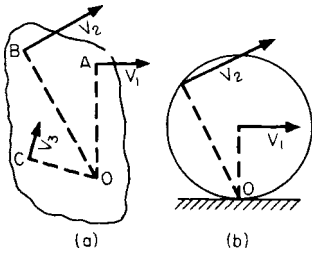

Fig. 3.1.55

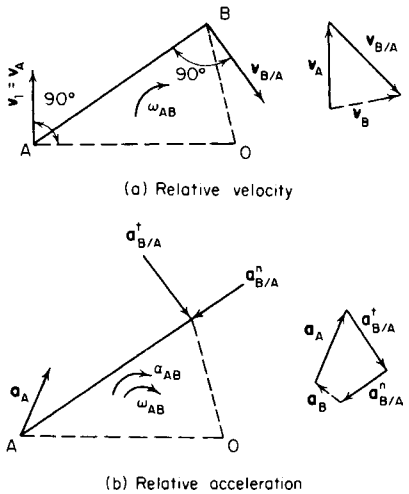

Fig. 3.1.56

If B is a point on a path which lies on the same rigid body as the line AB, a **particle** P **traveling on the path** will have a velocity $\mathbf{v}_p$ at the instant P passes over point B such that $\mathbf{v}_P = \mathbf{v}_A + \mathbf{v}_{B/A} + \mathbf{v}_{P/B}$, where the velocity $\mathbf{v}_{P/B}$ is the velocity of P relative to point B.

The particle P will have an acceleration $\mathbf{a}_P$ at the instant P passes over the point B such that $\mathbf{a}_P = \mathbf{a}_A + \mathbf{a}_{B/A} + \mathbf{a}_{P/B} + 2\omega_{AB} \times \mathbf{v}_{P/B}$. The term $\mathbf{a}_{P/B}$ is the acceleration of P relative to the path at point B. The last term $2\omega_{AB}\,\mathbf{v}_{P/B}$ is frequently referred to as the **coriolis acceleration.** The direction is always normal to the path in a sense which would rotate the head of the vector $\mathbf{v}_{P/B}$ about its tail in the direction of the angular velocity of the rigid body ω_{AB}.

EXAMPLE. In Fig. 3.1.57, arm AB is rotating counterclockwise about A with a constant angular velocity of 38 r/min or 4 rad/s, and the slider moves outward with a velocity of 10 ft/s (3.05 m/s). At an instant when the slider P is 30 in (0.76 m) from the center A, the acceleration of the slider will have two components. One component is the normal acceleration directed toward the center A. Its magnitude is $\omega^2 r = 4^2\,(30/12) = 40$ ft/s^2 $[\omega^2 r = 4^2\,(0.76) = 12.2$ m/s$^2]$. The second is the coriolis acceleration directed normal to the arm AB, upward and to the left. Its magnitude is $2\omega v = 2(4)(10) = 80$ ft/s^2 $[2\omega v = 2(4)(3.05) = 24.4$ m/s$^2]$.

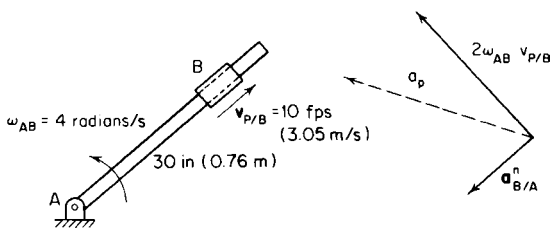

Fig. 3.1.57

General Motion of a Rigid Body

The general motion of a point moving in a coordinate system which is itself in motion is complicated and can best be summarized by using

vector notation. Referring to Fig. 3.1.58, let the point P be displaced a vector distance $\mathbf{R}$ from the origin O of a moving reference frame x, y, z which has a velocity $\mathbf{v}_o$ and an acceleration $\mathbf{a}_o$. If point P has a velocity and an acceleration relative to the moving reference plane, let these be $\mathbf{v}_r$ and $\mathbf{a}_r$. The angular velocity of the moving reference fame is ω, and

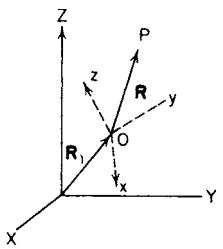

Fig. 3.1.58

the origin of the moving reference frame is displaced a vector distance $\mathbf{R}_1$ from the origin of a primary (fixed) reference frame X, Y, Z. The velocity and acceleration of P are $\mathbf{v}_P = \mathbf{v}_o + \omega \times \mathbf{R} + \mathbf{v}_r$ and $\mathbf{a}_P = \mathbf{a}_o + (d\omega/dt) \times \mathbf{R} + \omega \times (\omega \times \mathbf{R}) + 2\omega \times \mathbf{v}_r + \mathbf{a}_r$.

DYNAMICS OF PARTICLES

Consider a particle of mass m subjected to the action of forces $\mathbf{F}_1, \mathbf{F}_2, \mathbf{F}_3, \ldots$, whose vector resultant is $\mathbf{R} = \Sigma\mathbf{F}$. According to Newton's first law of motion, if $\mathbf{R} = 0$, the body is acted on by a balanced force system, and it will either remain at rest or move uniformly in a straight line. If $\mathbf{R} \neq 0$, Newton's second law of motion states that the body will accelerate in the direction of and proportional to the magnitude of the resultant R. This may be expressed as $\Sigma\mathbf{F} = m\mathbf{a}$. If the resultant of the force system has components in the x, y, and z directions, the resultant acceleration will have proportional components in the x, y, and z direction so that $F_x = ma_x$, $F_y = ma_y$, and $F_z = ma_z$. If the resultant of the force system varies with time, the acceleration will also vary with time.

In **rectilinear motion,** the acceleration and the direction of the unbalanced force must be in the direction of motion. **Forces must be in balance and the acceleration equal to zero in any direction other than the direction of motion.**

EXAMPLE 1. The body in Fig. 3.1.59 has a mass of 90 lbm (40.8 kg) and is subjected to an external horizontal force of 36 lbf (160 N) applied in the direction shown. The coefficient of friction between the body and the inclined plane is 0.1. Required, the velocity of the body at the end of 5 s, if it starts from rest.

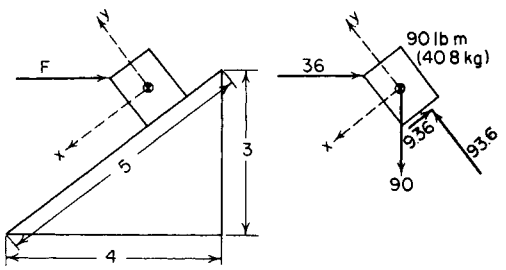

Fig. 3.1.59

First determine all the forces acting externally on the body. These are the applied force $F = 36$ lbf (106 N), the weight $W = 90$ lbf (400 N), and the force with which the plane reacts on the body. The latter force can be resolved into component forces, one normal and one parallel to the surface of the plane. Motion will be downward along the plane since a static analysis will show that the body will slide downward unless the static coefficient of friction is greater than 0.269. In the direction normal to the surface of the plane, the forces must be balanced. The normal force is $(3/5)(36) + (4/5)(90) = 93.6$ lbf (416 N). The frictional force is $93.6 \times 0.1 = 9.36$ lbf (41.6 N). The unbalanced force acting on the body along the plane is $(3/5)(90) - (4/5)(36) - 9.36 = 15.84$ lbf (70.46 N) downward. $F = (W/9)\,a = (90/g)\,a$; therefore, $a = 0.176\,g = 5.66$ ft/s^2 (1.725 m/s^2). In SI units, $F = ma = 70.46 = 40.8a$; and $a = 1.725$ m/s^2. The body is acted upon by constant forces and starts from rest; therefore, $v = \int_0^5 a\,dt$, and at the end of 5 s, the velocity would be 28.35 ft/s (8.91 m/s).

EXAMPLE 2. The force with which a rope acts on a body is equal and opposite to the force with which the body acts on the rope, and each is equal to the tension in the rope. In Fig. 3.1.60*a*, neglecting the weight of the pulley and the rope, the tension in the cord must be the force of 27 lbf. For the 18-lb mass, the unbalanced force is $27 - 18 = 9$ lbf in the upward direction, i.e., $27 - 18 = (18/g)a$, and $a = 16.1$ ft/s^2 upward. In Fig. 3.1.60*b* the 27-lb force is replaced by a 27-lb mass. The unbalanced force is still $27 - 18 = 9$ lbf, but it now acts on two masses so that $27 - 18 = (45a/g)$ and $a = 6.44$ ft/s^2. The 18-lb mass is accelerated upward, and the 27-lb mass is accelerated downward. The tension in the rope is equal to 18 lbf plus the unbalanced force necessary to give it an upward acceleration of $g/5$ or $T = 18 + (18/g)(g/5) = 21.6$ lbf. The tension is also equal to 27 lbf less the unbalanced force necessary to give it a downward acceleration of $g/5$ or $T = 27 - (27/g) \times (g/5) = 21.6$ lbf.

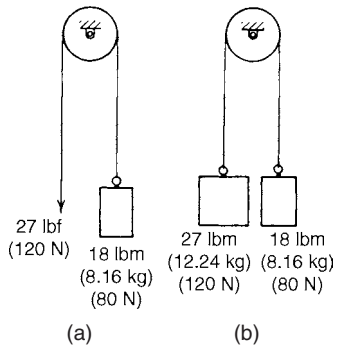

Fig. 3.1.60

In SI units, in Fig. 3.1.60*a*, the unbalanced force is $120 - 80 = 40$ N, in the upward direction, i.e., $120 - 80 = 8.16a$, and $a = 4.9$ m/s^2 (16.1 ft/s^2). In Fig. 3.1.60*b* the unbalanced force is still 40 N, but it now acts on the two masses so that $120 - 80 = 20.4a$ and $a = 1.96$ m/s^2 (6.44 ft/s^2). The tension in the rope is the weight of the 8.16-kg mass in newtons plus the unbalanced force necessary to give it an upward acceleration of 1.96 m/s^2, $T = 9.807(8.16) + (8.16)(1.96) = 96$ N (21.6 lbf).

General Formulas for the Motion of a Body under the Action of a Constant Unbalanced Force

Let s = distance, ft; a = acceleration, ft/s^2; v = velocity, ft/s; v_0 = initial velocity, ft/s; h = height, ft; F = force; m = mass; w = weight; g = acceleration due to gravity.

Initial velocity = 0

$$F = ma = (w/g)a$$
$$v = at$$
$$s = \tfrac{1}{2}at^2 = \tfrac{1}{2}vt$$
$$v = \sqrt{2as}$$
$$= \sqrt{2gh} \text{ (falling freely from rest)}$$

Initial velocity = v_0

$$F = ma = (w/g)a$$
$$v = v_0 + at$$
$$s = v_0t + \tfrac{1}{2}at^2 = \tfrac{1}{2}v_0t + \tfrac{1}{2}vt$$

If a body is to be moved in a straight line by a force, the line of action of this force must pass through its center of gravity.

General Rule for the Solution of Problems When the Forces Are Constant in Magnitude and Direction

Resolve all the forces acting on the body into two components, one in the direction of the body's motion and one at right angles to it. Add the

components in the direction of the body's motion algebraically and find the **unbalanced force,** if any exists.

In **curvilinear motion,** a particle moves along a curved path, and the resultant of the unbalanced force system may have components in directions other than the direction of motion. **The acceleration in any given direction is proportional to the component of the resultant in that direction.** It is common to utilize orthogonal coordinate systems such as **cartesian coordinates, polar coordinates,** and **normal and tangential coordinates** in analyzing forces and accelerations.

EXAMPLE. A conical pendulum consists of a weight suspended from a cord or light rod and made to rotate in a horizontal circle about a vertical axis with a constant angular velocity of N r/min. For any given constant speed of rotation, the angle θ, the radius r, and the height h will have fixed values. Looking at Fig. 3.1.61, we see that the forces in the vertical direction must be balanced, $T \cos \theta = w$. The forces in the direction normal to the circular path of rotation are unbalanced such that $T \sin \theta = (w/g)a_n = (w/g)\omega^2 r$. Substituting $r = l \sin \theta$ in this last equation gives the value of the tension in the cord $T = (w/g)l\omega^2$. Dividing the second equation by the first and substituting $\tan \theta = r/h$ yields the additional relation that $h = g/\omega^2$.

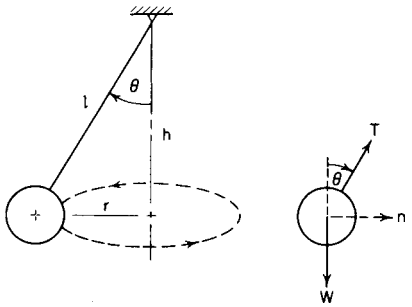

Fig. 3.1.61

An unresisted **projectile** has a motion compounded of the vertical motion of a falling body, and of the horizontal motion due to the horizontal component of the velocity of projection. In Fig. 3.1.62 the only force acting after the projectile starts is gravity, which causes an accelerating downward. The horizontal component of the original velocity v_0 is not changed by gravity. The projectile will rise until the velocity

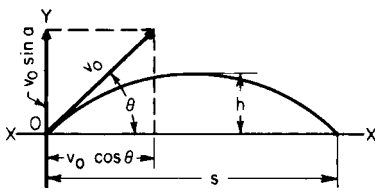

Fig. 3.1.62

given to it by gravity is equal to the vertical component of the starting velocity v_0, and the equation $v_0 \sin \theta = gt$ gives the time t required to reach the highest point in the curve. The same time will be taken in falling if the surface XX is level, and the projectile will therefore be in flight $2t$ s. The distance $s = v_0 \cos \theta \times 2t$, and the maximum height of ascent $h = (v_0 \sin \theta)^2/2g$. The expressions for the coordinates of any point on the path of the projectile are: $x = (v_0 \cos \theta)t$, and $y = (v_0 \sin \theta)t - \frac{1}{2} gt^2$, giving $y = x \tan \theta - (gx^2/2v_0^2 \cos^2 \theta)$ as the equation for the curve of the path. The radius of curvature of the highest point may be found by using the general expression $v^2 = gr$ and solving for r, v being taken equal to $v_0 \cos \theta$.

Simple Pendulum The period of oscillation $= \tau = 2\pi\sqrt{l/g}$, where l is the length of the pendulum and the length of the swing is not great compared to l.

Centrifugal and Centripetal Forces When a body revolves about an axis, some connection must exist capable of applying force enough to the body to constantly deviate it toward the axis. This deviating force is known as **centripetal force.** The equal and opposite resistance offered by the body to the connection is called the **centrifugal force.** The acceleration toward the axis necessary to keep a particle moving in a circle about that axis is v^2/r; therefore, the force necessary is $ma = mv^2/r = wv^2/gr = w\pi^2N^2r/900g$, where N = r/min. This force is constantly directed toward the axis.

The centrifugal force of a solid body revolving about an axis is the same as if the whole mass of the body were concentrated at its center of gravity. Centrifugal force $= wv^2/gr = mv^2/r = w\omega^2 r/g$, where w and m are the weight and mass of the whole body, r is the distance from the axis about which the body is rotating to the center of gravity of the body, ω the angular velocity of the body about the axis in radians, and v the linear velocity of the center of gravity of the body.

Balancing

A rotating body is said to be in **standing balance** when its center of gravity coincides with the axis upon which it revolves. Standing balance may be obtained by resting the axle carrying the body upon two horizontal plane surfaces, as in Fig. 3.1.63. If the center of gravity of the wheel A lies on the axis of the shaft B, there will be no movement, but if the center of gravity does not lie on the axis of the shaft, the shaft will roll until the center of gravity of the wheel comes directly under the

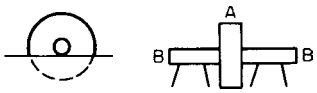

Fig. 3.1.63

axis of the shaft. The center of gravity may be brought to the axis of the shaft by adding or taking away weight at proper points on the diameter passing through the center of gravity and the center of the shaft. Weights may be added to or subtracted from any part of the wheel so long as its center of gravity is brought to the center of the shaft.

A rotating body may be in standing balance and not in **dynamic balance.** In Fig. 3.1.64, AA and BB are two disks whose centers of gravity are at o and p, respectively. The shaft and the disks are in standing balance if the disks are of the same weight and the distances of o and p from the center of the shaft are equal, and o and p lie in the same axial plane but on opposite sides of the shaft. Let the weight of each disk be w and the distances of o and p from the center of the shaft each be equal to r.

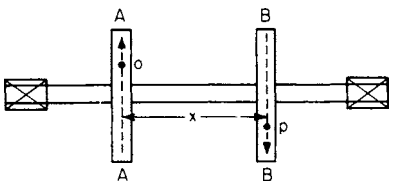

Fig. 3.1.64

The force exerted on the shaft by AA is equal to $w\omega^2 r/g$, where ω is the angular velocity of the shaft. Also, the force exerted on the shaft by $BB = w\omega^2 r/g$. These two equal and opposite parallel forces act at a distance x apart and constitute a couple with a moment tending to rotate the shaft, as shown by the arrows, of $(w\omega^2 r/g)x$. A couple cannot be balanced by a single force; so two forces at least must be added to or subtracted from the system to get dynamic balance.

Systems of Particles The principles of motion for a single particle can be extended to cover a **system of particles.** In this case, **the vector resultant of all external forces acting on the system of particles must equal the total mass of the system times the acceleration of the mass center, and the direction of the resultant must be the direction of the acceleration of the mass center.** This is the **principle of motion of the mass center.**

Rotation of Solid Bodies in a Plane about Fixed Axes

For a rigid body revolving **in a plane** about a fixed axis, **the resultant moment about that axis must be equal to the product of the moment of inertia (about that axis) and the angular acceleration,** $\Sigma M_0 = I_0\alpha$. This is a general statement which includes the particular case of rotation about an axis that passes through the center of gravity.

Rotation about an Axis Passing through the Center of Gravity The rotation of a body about its center of gravity can only be caused or changed by a **couple.** See Fig. 3.1.65. If a single force F is applied to the wheel, the axis immediately acts on the wheel with an equal force to prevent translation, and the result is a couple (moment Fr) acting on the body and causing rotation about its center of gravity.

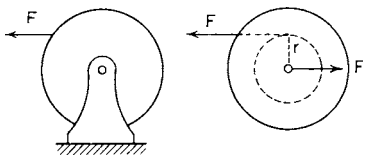

Fig. 3.1.65

General formulas for rotation of a body about a fixed axis through the center of gravity, if a constant unbalanced moment is applied (Fig. 3.1.65).

Let θ = angular displacement, rad; ω = angular velocity, rad/s; α = angular acceleration, rad/s^2; M = unbalanced moment, ft · lb; I = moment of inertia (mass); g = acceleration due to gravity; t = time of application of M.

Initial angular velocity = 0	Initial angular velocity = ω_0
$M = I\alpha$	$M = I\alpha$
$\theta = \frac{1}{2}\alpha t^2$	$\theta = \omega_0 t + \frac{1}{2}\alpha t^2$
$\omega = \sqrt{2\alpha\theta}$	$\omega = \sqrt{\omega_0^2 + 2\alpha\theta}$

General Rule for Rotating Bodies Determine all the external forces acting and their moments about the axis of rotation. If these moments are balanced, there will be no change of motion. If the moments are unbalanced, this unbalanced moment, or **torque,** will cause an angular acceleration about the axis.

Rotation about an Axis Not Passing through the Center of Gravity **The resultant force acting on the body must be proportional to the acceleration of the center of gravity and directed along its line of action.** If the axis of rotation does not pass through the center of gravity, the center of gravity will have a resultant acceleration with a component $a_n = \omega^2 r$ directed toward the axis of rotation and a component $a_t = \alpha r$ tangential to its circular path. The resultant force acting on the body must also have two components, one directed normal and one directed tangential to the path of the center of gravity. The line of action of this resultant does not pass through the center of gravity because of the unbalanced moment $M_0 = I_0\alpha$ but at a point Q, as in Fig. 3.1.66. The point of application of this resultant is known as the **center of percussion** and may be **defined** as the point of application of the resultant of all the forces tending to cause a body to rotate about a certain axis. It is the point at which a suspended

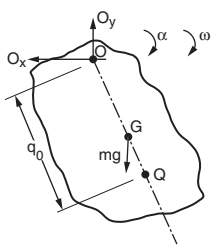

Fig. 3.1.66

body may be struck without causing any force on the axis passing through the point of suspension.

Center of Percussion The distance from the axis of suspension to the center of percussion is $q_0 = I/mr_G$, where I = moment of inertia of the body about its axis of suspension and r_G is the distance from the axis of suspension to the center of gravity of the body.

EXAMPLES. 1. Find the center of percussion of the homogeneous rod (Fig. 3.1.67) of length L and mass m, suspended at XX.

$$q_0 = \frac{1}{mr_G}$$

$$I \approx \frac{m}{L}\int_0^L r^2\,dr = mL^2/3 \qquad r_G = L/2 \qquad \therefore\ q_0 = \frac{mL^2/3}{mL/2} = 2L/3$$

2. Find the center of percussion of a solid cylinder, of mass m, resting on a horizontal plane. In Fig. 3.1.68, the instantaneous center of the cylinder is at O, and serves temporarily as a fixed axis of rotation. The center of percussion will therefore be a height above the plane equal to $q_0 = I/mx_0$. Since $I = (mr^2/2) + mr^2$ and $x_0 = r$, $q_0 = 3r/2$.

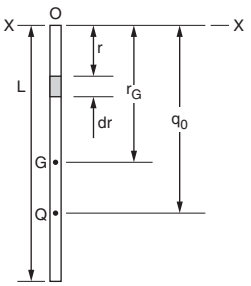

Fig. 3.1.67

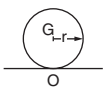

Fig. 3.1.68

Wheel or Cylinder Rolling down a Plane In this case the component of the weight along the plane tends to make it roll down and is treated as a force causing rotation. The forces acting on the body should be resolved into components along the line of motion and perpendicular to it. If the forces are all known, their resultant is at the center of percussion. If one force is to be determined (the exact conditions as regards slipping or not slipping must be known), the center of percussion can be determined and the unknown force found.

Relation between the Center of Percussion and Radius of Gyration $q_0 = I/mr_G = k^2/r_G \therefore k^2 = r_G q_0$ where k = radius of gyration. Therefore, the radius of gyration is a mean proportional between the distance from the axis of oscillation to the center of percussion and the distance from the same axis to the center of gravity.

Interchangeability of Center of Percussion and Axis of Oscillation If a body is suspended from an axis, the center of percussion for that axis can be found. If the body is suspended from this center of percussion as an axis, the original axis of suspension will then become the center of percussion. The center of percussion is sometimes known as the **center of oscillation.**

Period of Oscillation of a Compound Pendulum The length of an equivalent simple pendulum is the distance from the axis of suspension to the center of percussion of the body in question. To find the **period of oscillation** of a body about a given axis, find the distance $q_0 = I/mr_G$ from that axis to the center of percussion of the swinging body. The length of the simple pendulum that will oscillate in the same time is this distance q_0. The period of oscillation for the equivalent single pendulum is $\tau = 2\pi\sqrt{q_0/g}$.

Determination of Moment of Inertia by Experiment To find the moment of inertia of a body, suspend it from some axis not passing through the center of gravity and, by swinging it, determine the period of one complete oscillation in seconds. The known values will then be τ = time of one complete oscillation, r_G = distance from axis to center of gravity, and m = mass of body. The length of the equivalent simple pendulum is $q_0 = I/mr_G$. Substituting this value of q_0 in $\tau = 2\pi\sqrt{q_0/g}$ gives $\tau = 2\pi\sqrt{I/mr_G g}$, from which $\tau^2 = 4\pi^2 I/mr_G g$, or $I = mr_G g\tau^2/4\pi^2$.

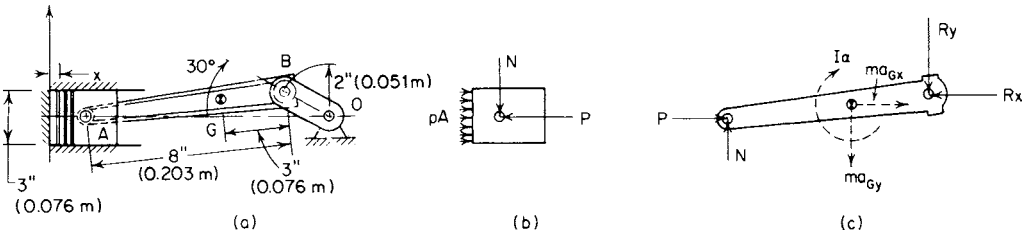

Fig. 3.1.69

Plane Motion of a Rigid Body

Plane motion may be considered to be a combination of translation and rotation (see "Kinematics"). For translation, Newton's second law of motion must always be satisfied, and the resultant of the external force system must be equal to the product of the mass times the acceleration of the center of gravity in any system of coordinates. In rotation, the body moving in plane motion will not have a fixed axis. When the methods of relative motion are being used, any point on the body may be used as a reference axis to which the motion of all other points is referred.

The sum of the moments of all external forces about the reference axis must be equal to the vector sum of the centroidal moment of inertia times the angular acceleration and the amount of the resultant force about the reference axis.

EXAMPLE. Determine the forces acting on the piston pin A and the crankpin B of the connecting rod of a reciprocating engine shown in Fig. 3.1.69 for a position of 30° from TDC. The crankshaft speed is constant at 2,000 r/min. Assume that the pressure of expanding gases on the 4-lbm (1.81-kg) piston at this point is 145 lb/in^2 (10^6 N/m^2). The connecting rod has a mass of 5 lbm (2.27 kg) and has a centroidal radius of gyration of 3 in (0.076 m).

The kinematics of the problem are such that the angular velocity of the crank is $\omega_{OB} = 209.4$ rad/s clockwise, the angular velocity of the connecting rod is $\omega_{AB} = 45.7$ rad/s counterclockwise, and the angular acceleration is $\alpha_{AB} = 5{,}263$ rad/s^2 clockwise. The linear acceleration of the piston is 7,274 ft/s^2 in the direction of the crank. From the free-body diagram of the piston, the horizontal component of the piston-pin force is $145 \times (\pi/4)(5^2) - P = (4/32.2)(7{,}274)$, $P = 1{,}943$ lbf. The acceleration of the center of gravity G is the vector sum of the component accelerations $a_G = a_B + a^n_{G/B} + a^l_{G/B}$ where $a^n_{G/B} = \omega^2_{GB} \cdot r_{GB} = 3/12(45.7)^2 = 522$ ft/s^2 and $a^l_{G/B} = \alpha_{GB} \cdot r_{GB} = 3/12(5.263) = 1{,}316$ ft/s^2. The resultant acceleration of the center of gravity is 6,685 ft/s^2 in the x direction and 2,284 ft/s^2 in the negative y direction. The resultant of the external force system will have corresponding components such that $ma_{Gx} = (5/32.2)(6{,}685) = 1{,}039$ lbf and $ma_{Gy} = (5/32.2)(2{,}284) = 355$ lbf. The three remaining unknown forces can be found from the three equations of motion for the connecting rod.

Taking the sum of the forces in the x direction, $\epsilon F = ma_{Gx}$; $P - R_x = ma_{Gx}$, and $R_x = 905.4$ lbf. In the y direction, $\Sigma F = ma_{Gy}$; $R_y - N = ma_{gy}$; this has two unknowns, R_y and N. Taking the sum of the moments of the external forces about the center of mass g, $\Sigma M_G = I_G \alpha AB$; $(N)(5) \cos(7.18°) - (P)(5) \sin(7.18°) + (R_y)(3) \cos(7.18°) - R_x(3) \sin(7.18°) - (5/386.4)(3)^2(5{,}263)$. Solving for R_y and N simultaneously, $R_y = 494.7$ lbf and $N = 140$ lbf. We could have avoided the solution of two simultaneous algebraic equations by taking the moment summation about end A, which would determine R_y independently, or about end B, which would determine N independently.

In SI units, the kinematics would be identical, the linear acceleration of the piston being 2,217 m/s^2 (7,274 ft/s^2). From the free-body diagram of the piston, the horizontal component of the piston-pin force is $(10^6) \times (\pi/4)(0.127)^2 - P = (1.81)(2{,}217)$, and $P = 8{,}640$ N. The components of the acceleration of the center of gravity G are $a^n_{G/B} = 522$ ft/s^2 and $a^T_{G/B} = 1{,}315$ ft/s^2. The resultant acceleration of the center of gravity is 2,037.5 m/s^2 (6,685 ft/s^2) in the x direction and 696.3 m/s^2 (2,284 ft/s^2) in the negative y direction. The resultant of the external force system will have the corresponding components; $ma_{Gx} = (2.27)(2{,}037.5) = 4{,}620$ N; $ma_{Gy} = (2.27)(696.3) = 1{,}579$ N. $R_x = 4{,}027$ N, $R_y = 2{,}201$ N, force $N = 623$ newtons.

WORK AND ENERGY

Work When a body is displaced against resistance or accelerated, work must be done upon it. An increment of work is defined as the product of an incremental displacement and the component of the force vector in the direction of the displacement or the product of the component of the incremental displacement and the force in the direction of the force. $dU = F \cdot ds \cos \alpha$, where α is the angle between the vector displacement and the vector force. The increment of work done by a couple M acting in a body during an increment of angular rotation $d\theta$ in the plane of the couple is $dU = M\, d\theta$. In a force-displacement or moment-angle diagram, called a **work diagram** (Fig. 3.1.70), force is plotted as a function of displacement. The area under the curve represents the work done, which is equal to $\int_{s_1}^{s_2} F\, ds \cos\alpha$ or $\int_{\theta_1}^{\theta_2} M\, d\theta$.

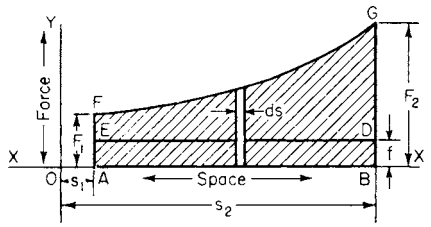

Fig. 3.1.70

Units of Work When the force of 1 lb acts through the distance of 1 ft, 1 lb · ft of work is done. In SI units, a force of 1 newton acting through 1 metre is 1 joule of work. 1.356 N · m = 1 lb · ft.

Energy A body is said to possess energy when it can do work. A body may possess this capacity through its **position** or **condition.** When a body is so held that it can do work, if released, it is said to possess energy of position or **potential energy.** When a body is moving with some velocity, it is said to possess energy of motion or **kinetic energy.** An example of potential energy is a body held suspended by a rope; the position of the body is such that if the rope is removed work can be done by the body.

Energy is expressed in the same units as work. The kinetic energy of a particle is expressed by the formula $E = \frac{1}{2}mv^2 = \frac{1}{2}(w/g)v^2$. The kinetic energy of a rigid body in translation is also expressed as $E = \frac{1}{2}mv^2$. Since all particles of the rigid body have the same identical velocity v, the velocity v is the velocity of the center of gravity. The kinetic energy of a rigid body, rotating about a fixed axis is $E = \frac{1}{2}I_0\omega^2$, where I_0 is the mass moment of inertia about the axis of rotation. In plane motion, a rigid body has both translation and rotation. The kinetic energy is the algebraic sum of the translating kinetic energy of the center of gravity and the rotating kinetic energy about the center of gravity, $E = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2$. Here the velocity v is the velocity of the center of gravity, and the moment of inertia I is the centroidal moment of inertia.

If a force which varies acts through a space on a body of mass m, the work done is $\int_{s_i}^{s} F\, ds$, and if the work is all used in giving kinetic energy to the body it is equal to $\frac{1}{2}m(v_2^2 - v_1^2)$ = **change in kinetic energy,** where v_2 and v_1 are the velocities at distances s_2 and s_1, respectively. This is a specific statement of the law of conservation of energy. **The principle of conservation of energy requires that the mechanical energy of a system remain unchanged if it is subjected only to forces which depend on position or configuration.**

Certain problems in which the velocity of a body at any point in its straight-line path when acted upon by varying forces is required can be easily solved by the use of a **work diagram.**

In Fig. 3.1.70, let a body start from rest at A and be acted upon by a force that varies in accordance with the diagram $AFGBA$. Let the resistance to motion be a constant force $= f$. Find the velocity of the body at point B. The area $AFGBA$ represents the work done upon the body and the area $AEDBA$ (= force $f \times$ distance AB) represents the work that must be done to overcome resistance. The difference of these areas, or $EFGDE$, will represent work done in excess of that required to overcome resistance, and consequently is equal to the increase in kinetic energy. Equating the work represented by the area $EFGDE$ to $\frac{1}{2}wv^2/g$ and solving for v will give the required velocity at B. If the body did not start from rest, this area would represent the change in kinetic energy, and the velocity could be obtained by the formula: Work $= \frac{1}{2}(w/g)(v_1^2 - v_0^2)$, v_1 being the required velocity.

General Rule for Rectilinear Motion Resolve each force acting on the body into components, one of which acts along the line of motion of the body and the other at right angles to the line of motion. Take the sum of all the components acting in the direction of the motion and multiply this sum by the distance moved through for constant forces. (Take the average force times distance for forces that vary.) This product will be the total work done upon the body. If there is no unbalanced component, there will be no change in kinetic energy and consequently no change in velocity. If there is an unbalanced component, the change in kinetic energy will be this unbalanced component multiplied by the distance moved through.

The **work done by a system of forces acting on a body** is equal to the algebraic sum of the work done by each force taken separately.

Power is the rate at which work is performed, or the number of units of work performed in unit time. In the English engineering system, the units of power are the horsepower, or 33,000 lb · ft/min = 550 lb · ft/s, and the kilowatt = 1.341 hp = 737.55 lb · ft/s. In SI units, the unit of power is the watt, which is 1 newton-metre per second or 1 joule per second.

Friction Brake In Fig. 3.1.71 a pulley revolves under the band and in the direction of the arrow, exerting a pull of T on the spring. The friction of the band on the rim of the pulley is $(T - w)$, where w is the weight attached to one end of the band. Let the pulley make N r/min; then the work done per minute against friction by the rim of the pulley is $2\pi RN(T - w)$, and the horsepower absorbed by brake $= 2\pi RN(T - w)/33{,}000$.

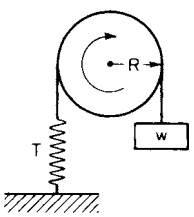

Fig. 3.1.71

IMPULSE AND MOMENTUM

The product of force and time is defined as linear impulse. The impulse of a constant force over a time interval $t_2 - t_1$ is $F(t_2 - t_1)$. If the force is not constant in magnitude but is constant in direction, the impulse is $\int_{t_1}^{t_2} F\,dt$. The dimensions of linear impulse are (force) × (time) in pound-seconds, or newton-seconds.

Impulse is a **vector** quantity which has the direction of the resultant force. Impulses may be added vectorially by means of a vector polygon, or they may be resolved into components by means of a parallelogram. The **moment** of a **linear impulse** may be found in the same manner as the moment of a force. The linear impulse is represented by a directed line segment, and the moment of the impulse is the product of the magnitude of the impulse and the perpendicular distance from the line segment to the point about which the moment is taken. **Angular impulse** over a time interval $t_2 - t_1$ is a product of the sum of applied moments on a rigid body about a reference axis and time. The dimensions for angular impulse are (force) × (time) × (displacement) in foot-pound-seconds or newton-metre-seconds. **Angular impulse and linear impulse cannot be added.**

Momentum is also a vector quantity and can be added and resolved in the same manner as force and impulse. The dimensions of linear momentum are (force) × (time) in pound-seconds or newton-seconds, and are identical to linear impulse. An alternate statement of Newton's second law of motion is that the resultant of an unbalanced force system must be equal to the time rate of change of linear momentum, $\Sigma\mathbf{F} = d(mv)/dt$.

If a variable force acts for a certain time on a body of mass m, the quantity $\int_{t_1}^{t_2} F\,dt = m(v_2 - v_1) =$ the change of momentum of the body.

The **moment of momentum** can be determined by the same methods as those used for the moment of a force or moment of an impulse. The dimensions of the moment of momentum are (force) × (time) × (displacement) in foot-pound-seconds, or newton-metre-seconds.

In **plane motion** the angular momentum of a rigid body about a reference axis perpendicular to the plane of motion is the sum of the moments of linear momenta of all particles in the body about the reference axes. Specifically, **the angular momentum of a rigid body in plane motion is the vector sum of the angular momentum about the reference axis and the moment of the linear momentum of the center of gravity about the reference axis,** $\mathbf{H}_0 = I_0\omega + \mathbf{d} \times mv$.

In three-dimensional rotation about a fixed axis, the angular momentum of a rigid body has components along three coordinate axes, which involve both the moments of inertia about the x, y, and z axes, $I_{0_{xx}}$, $I_{0_{yy}}$, and $I_{0_{zz}}$, and the products of inertia, $I_{0_{xy}}$, $I_{0_{zz}}$, and $I_{0_{yz}}$; $H_{0_x} - I_{0_{xx}} \cdot \omega_x - I_{0_{xy}} \cdot \omega_y - I_{0_{xy}} \cdot \omega_z$, $H_{0_y} = -I_{0_{xy}} \cdot \omega_x + I_{0_{yy}} \cdot \omega_y - I_{0_{yz}} \cdot \omega_z$, and $H_{0_z} = I_{0_{xz}} \cdot \omega_x - I_{0_{zy}} \cdot \omega_y + I_{0_{zz}} \cdot \omega_z$ where $\mathbf{H}_0 = \mathbf{H}_{0_x} + \mathbf{H}_{0_y} + \mathbf{H}_{0_z}$.

Impact

The collision between two bodies, where relatively large forces result over a comparatively short interval of time, is called **impact.** A straight line perpendicular to the plane of contact of two colliding bodies is called the **line of impact.** If the centers of gravity of the two bodies lie on the line of contact, the impact is called **central impact,** in any other case, **eccentric impact.** If the linear momenta of the centers of gravity are also directed along the line of impact, the impact is **collinear or direct central impact.** In any other case impact is said to be **oblique.**

Collinear Impact When two masses m_1 and m_2, having respective velocities u_1 and u_2, move in the same line, they will collide if $u_2 > u_1$ (Fig. 3.1.72*a*). During collision (Fig. 3.1.72*b*), kinetic energy is absorbed

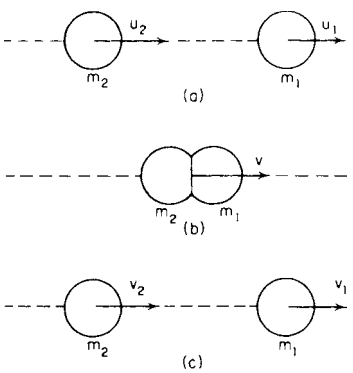

Fig. 3.1.72

in the deformation of the bodies. There follows a period of restoration which may or may not be complete. If complete restoration of the energy of deformation occurs, the impact is **elastic.** If the restoration of energy is incomplete, the impact is referred to as **inelastic.** After collision (Fig. 3.1.72*c*), the bodies continue to move with changed velocities of v_1 and v_2. Since the contact forces on one body are equal to and opposite the contact forces on the other, the sum of the linear momenta of the two bodies is conserved; $m_1u_1 + m_2u_2 = m_1v_1 + m_2v_2$.

The law of conservation of momentum states that the linear momentum of a system of bodies is unchanged if there is no resultant external force on the system.

Coefficient of Restitution The ratio of the velocity of separation $v_1 - v_2$ to the velocity of approach $u_2 - u_1$ is called the **coefficient of restitution** e; $e = (v_1 - v_2)/(u_2 - u_1)$.

The value of e will depend on the shape and material properties of the colliding bodies. In elastic impact, the coefficient of restitution is unity and there is no energy loss. A coefficient of restitution of zero indicates perfectly inelastic or plastic impact, where there is no separation of the bodies after collision and the energy loss is a maximum. In **oblique impact,** the coefficient of restitution applies only to those components of velocity along the line of impact or normal to the plane of impact. The coefficient of restitution between two materials can be measured by making one body many times larger than the other so that m_2 is infinitely large in comparison to m_1. The velocity of m_2 is unchanged for all practical purposes during impact and $e = v_1/u_1$. For a small ball dropped from a height H upon an extensive horizontal surface and rebounding to a height h, $e = \sqrt{h/H}$.

Impact of Jet Water on Flat Plate When a jet of water strikes a flat plate perpendicularly to its surface, the force exerted by the water on the plate is wv/g, where w is the weight of water striking the plate in a unit of time and v is the velocity. When the jet is inclined to the surface by an angle, A, the force is $(wv/g) \cos A$.

Variable Mass

If the mass of a body is variable such that mass is being either added or ejected, an alternate form of Newton's second law of motion must be used which accounts for changes in mass:

$$\mathbf{F} = m\frac{d\mathbf{v}}{dt} + \frac{dm}{dt}\mathbf{u}$$

The mass m is the instantaneous mass of the body, and dv/dt is the time rate of change of the absolute of velocity of mass m. The velocity u is the velocity of the mass m relative to the added or ejected mass, and dm/dt is the time rate of change of mass. In this case, care must be exercised in the choice of coordinates and expressions of sign. If mass is being added, dm/dt is plus, and if mass is ejected, dm/dt is minus.

Fields of Force—Attraction

The space within which the action of a physical force comes into play on bodies lying within its boundaries is called the **field of the force.**

The **strength** or **intensity of the field** at any given point is the relation between a force F acting on a mass m at that point and the mass. Intensity of field $= i = F/m$; $F = mi$.

The **unit of field intensity** is the same as the unit of acceleration, i.e., 1 ft/s^2 or 1 m/s^2. The intensity of a field of force may be represented by a line (or **vector**).

A field of force is said to be **homogeneous** when the intensity of all points is uniform and in the same direction.

A field of force is called a **central field of force** with a center O, if the direction of the force acting on the mass particle m in every point of the field passes through O and its magnitude is a function only of the distance r from O to m. A line so drawn through the field of force that its direction coincides at every point with that of the force prevailing at that point is called a **line of force.**

Rotation of Solid Bodies about Any Axis

The general moment equations for three-dimensional motion are usually expressed in terms of the angular momentum. For a reference axis O, which is either a fixed axis of the center of gravity, $M_{0_x} = (dH_{0_x}/dt) - H_{0_y} \cdot \omega_z + H_{0_z} \cdot \omega_y$, $M_{0_y} = (dH_{0_y}/dt) - H_{0_z} \cdot \omega_x + H_{0_x} \cdot \omega_z$, and $M_{0_z} = (dH_{0_z}/dt) - H_{0_x}\omega_y + H_{0_y}\omega_x$. If the coordinate axes are oriented to coincide with the principal axes of inertia, $I_{0_{xx}}, I_{0_{yy}}$, and $I_{0_{zz}}$, a similar set of three differential equations results, involving moments, angular velocity, and angular acceleration; $M_{0_x} = I_{0_{xx}}(d\omega_x/dt) + (I_{0_{zz}} - I_{0_{yy}})\omega_y \cdot \omega_z$, $M_{0_y} = I_{0_{yy}}(d\omega_y/dt) + (I_{0_{xx}} - I_{0_{zz}})\omega_z \cdot \omega_x$, and $M_{0_z} = I_{0_{zz}}(d\omega_z/dt) + (I_{0_{yy}} - I_{0_{xx}})\omega_x\omega_y$. These equations are known as **Euler's equations of motion** and may apply to any rigid body.

GYROSCOPIC MOTION AND THE GYROSCOPE

Gyroscopic motion can be explained in terms of Euler's equations. Let I_1, I_2, and I_3 represent the principal moments of inertia of a gyroscope spinning with a constant angular velocity ω, about axis 1, the subscripts 1, 2, and 3 representing a right-hand set of reference axes (Figs. 3.1.73 and 3.1.74). If the gyroscope is precessed about the third axis, a vector moment results along the second axis such that

$$M_2 = I_2(d\omega_2/dt) + (I_1 - I_3)\omega_3\omega_1$$

Where the precession and spin axes are at right angles, the term $(d\omega_2/dt)$ equals the component of $\omega_3 \times \omega_1$ along axis 2. Because of this, in the simple case of a body of symmetry, where $I_2 = I_3$, the gyroscopic

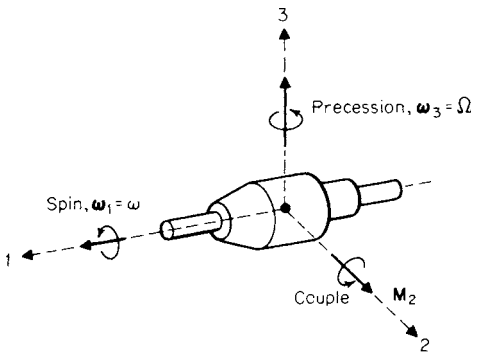

Fig. 3.1.73

moment can be reduced to the common expression $M = I\omega\Omega$, where Ω is the rate of precession, ω the rate of spin, and I the moment of inertia about the spin axis. It is important to realize that these are equations of motion and relate the applied or resulting gyroscopic moment due to forces which act *on* the rotor, as disclosed by a free-body diagram, to the resulting motion of the rotor.

Physical insight into the behavior of a steady precessing gyro with mutually perpendicular moment, spin, and precession axes is gained by recognizing from Fig. 3.1.74 that the change dH in angular momentum H is equal to the angular impulse $M\,dt$. In time dt, the angular-momentum

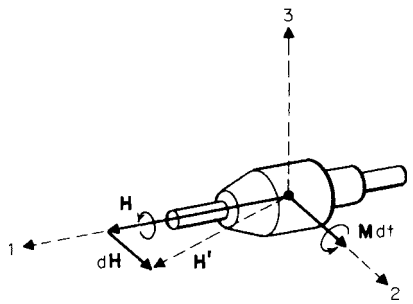

Fig. 3.1.74

vector swings from H *to* H', owing to the velocity of precession ω_3. The vector change dH in angular momentum is in the direction of the applied moment M. This fact is inherent in the basic moment-momentum equation and can always be used to establish the correct spatial relationships between the moment, precessional, and spin vectors. It is seen, therefore, from Fig. 3.1.74 that the spin axis always turns toward the moment axis. Just as the change in direction of the mass-center velocity is in the same direction as the resultant force, so does the change in angular momentum follow the direction of the applied moment.

For example, suppose an airplane is driven by a right-handed propeller (turning like a right-handed screw when moving forward). If a gust of wind or other force turns the machine to the *left,* the gyroscopic action of the propeller will make the forward end of the shaft strive to *rise;* if the wing surface is large, this motion will be practically prevented by the resistance of the air, and the gyroscopic forces become effective merely as internal stresses, whose maximum value can be computed by the formula above. Similarly, if the airplane is dipped *downward,* the gyroscopic action will make the forward end of the shaft strive to turn to the *left.*

Modern **applications** of the gyroscope are based on one of the following properties: (1) a gyroscope mounted in three gimbal rings so as to be entirely free angularly in all directions will retain its direction *in space* in the absence of outside couples; (2) if the axis of rotation of a gyroscope turns or precesses in space, a couple or torque acts on the gyroscope (and conversely on its frame).

Devices operating on the first principle are satisfactory only for short durations, say less than half an hour, because no gyroscope is entirely without outside couple. The friction couples at the various gimbal bearings, although small, will precess the axis of rotation so that after a while the axis of rotation will have changed its direction in space. The chief device based on the first principle is the **airplane compass,** which is a freely mounted gyro, keeping its direction in space during fast maneuvers of a fighting airplane. No magnetic compass will indicate correctly during such maneuvers. After the plane is back on an even keel in steady flight, the magnetic compass once more reads the true magnetic north, and the gyro compass has to be reset to point north again.

An example of a device operating on the second principle is the **automatic pilot** for keeping a vehicle on a given course. This device has been installed on torpedoes, ships, airplanes. When the ship or plane turns from the chosen course, a couple is exerted on the gyro axis, which makes it precess and this operates electric contacts or hydraulic or pneumatic valves. These again operate on the rudders, through relays, and bring the ship back to its course.

Another application is the ship **antirolling** gyroscope. This very large gyroscope spins about a vertical axis and is mounted in a ship so that the axis can be tipped fore and aft by means of an electric motor, the precession motor. The gyro can exert a large torque on the ship about the fore-and-aft axis, which is along the "rolling" axis. The sign of the torque is determined by the direction of rotation of the precession motor, which in turn is controlled by electric contacts operated by a small pilot gyroscope on the ship, which feels which way the ship rolls and gives the signals to apply a countertorque.

The **turn indicator** for airplanes is a gyro, the frame of which is held by springs. When the airplane turns, it makes the gyro axis turn with it, and the resultant couple is delivered by the springs. Thus the elongation of the springs is a measure of the rate of turn, which is suitably indicated by a pointer.

The most complicated and ingenious application of the gyroscope is the **marine compass.** This is a pendulously suspended gyroscope which is affected by gravity and also by the earth's rotation so that the gyro axis is in equilibrium only when it points north, i.e., when it lies in the plane formed by the local vertical and by the earth's north-south axis. If the compass is disturbed so that it points away from north, the action of the earth's rotation will restore it to the correct north position in a few hours.

3.2 FRICTION

by Vittorio (Rino) Castelli

Friction is the resistance that is encountered when two solid surfaces slide or tend to slide over each other. The surfaces may be either dry or lubricated. In the first case, when the surfaces are free from contaminating fluids, or films, the resistance is called **dry friction.** The friction of brake shoes on the rim of a railroad wheel is an example of dry friction.

When the rubbing surfaces are separated from each other by a very thin film of lubricant, the friction is that of **boundary** (or **greasy**) **lubrication.** The lubrication depends in this case on the strong adhesion of the lubricant to the material of the rubbing surfaces; the layers of lubricant slip over each other instead of the dry surfaces. A journal when starting, reversing, or turning at very low speed under a heavy load is an example of the condition that will cause boundary lubrication. Other examples are gear teeth (especially hypoid gears), cutting tools, wire-drawing dies, power screws, bridge trunnions, and the running-in process of most lubricated surfaces.

When the lubrication is arranged so that the rubbing surfaces are separated by a fluid film, and the load on the surfaces is carried entirely by the hydrostatic or hydrodynamic pressure in the film, the friction is that of **complete** (or **viscous**) **lubrication.** In this case, the frictional losses are due solely to the internal fluid friction in the film. Oil ring bearings, bearings with forced feed of oil, pivoted shoe-type thrust and journal bearings, bearings operating in an oil bath, hydrostatic oil pads, oil lifts, and step bearings are instances of complete lubrication.

Incomplete lubrication or mixed lubrication takes place when the load on the rubbing surfaces is carried partly by a fluid viscous film and partly by areas of boundary lubrication. The friction is intermediate between that of fluid and boundary lubrication. Incomplete lubrication exists in bearings with drop-feed, waste-packed, or wick-fed lubrication, or on parallel-surface bearings.

STATIC AND KINETIC COEFFICIENTS OF FRICTION

In the absence of friction, the resultant of the forces between the surfaces of two bodies pressing upon each other is normal to the surface of contact. With friction, the resultant deviates from the normal.

If one body is pressed against another by a force P, as in Fig. 3.2.1, the first body will not move, provided the angle a included between the line of action of the force and a normal to the surfaces in contact does not exceed a certain value which depends upon the nature of the surfaces. The reaction force R has the same magnitude and line of action as the force P. In Fig. 3.2.1, R is resolved into two components: a force N

normal to the surfaces in contact and a force F_r parallel to the surfaces in contact. From the above statement it follows that, for motion not to occur,

$$F_r = N \tan a_0 = Nf_0$$

where $f_0 = \tan a_0$ is called the **coefficient of friction of rest** (or of **static friction**) and a_0 is the **angle of friction at rest.**

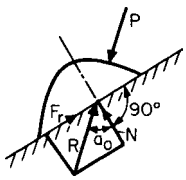

Fig. 3.2.1

If the normal force N between the surfaces is kept constant, and the tangential force F_r is gradually increased, there will be no motion while $F_r < Nf_0$. A state of *impending motion* is reached when F_r nears the value of Nf_0. If sliding motion occurs, a frictional force F resisting the motion must be overcome. The force F is commonly expressed as $F = fN$, where f is the **coefficient of sliding friction,** or **kinetic friction.** Normally, the coefficients of sliding friction are smaller than the coefficients of static friction. With small velocities of sliding and very clean surfaces, the two coefficients do not differ appreciably.

Table 3.2.4 demonstrates the typical reduction of sliding coefficients of friction below corresponding static values. Figure 3.2.2 indicates results of tests on lubricated machine tool ways showing a reduction of friction coefficient with increasing sliding velocity.

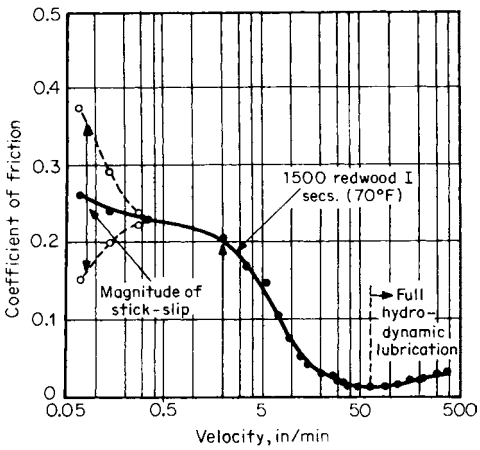

Fig. 3.2.2 Typical relationship between kinetic friction and sliding velocity for lubricated cast iron on cast iron slideways (load, 20 lb/in^2; upper slider, scraped; lower slideway, scraped). *(From Birchall, Kearny, and Moss, Intl. J. Machine Tool Design Research, 1962.)*

This behavior is normal with dry friction, some conditions of boundary friction, and with the break-away friction in ball and roller bearings. This condition is depicted in Fig. 3.2.3, where the friction force decreases with relative velocity. This negative slope leads to locally unstable equilibrium and **self-excited vibrations** in systems such as the one of Fig. 3.2.4. This phenomenon takes place because, for small amplitudes, the oscillatory system displays damping in which the damping factor is equal to the slope of the friction curve and thus is termed **negative damping.** When the slope of the friction force versus sliding velocity is positive (**positive damping**) this type of instability is not possible. This is typical of fluid damping, squeeze films, dash pots, and fluid film bearings in general.

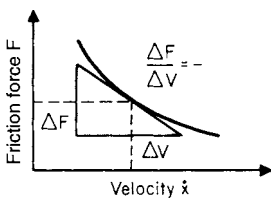

Fig. 3.2.3 Friction force decreases as velocity increases.

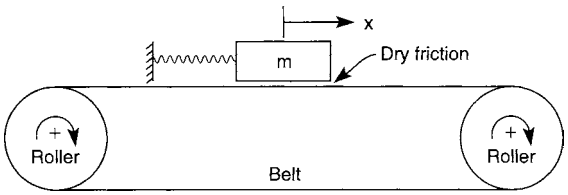

Fig. 3.2.4 Belt friction apparatus with possible self-excited vibrations.

It is interesting to note that these self-excited systems vibrate at close to their natural frequency over a large range of frictional levels and speeds. This symptom is a helpful means of identification. Another characteristic is that the moving body comes periodically to momentary relative rest, that is, zero sliding velocity. For this reason, this phenomenon is also called **stick-slip vibration.** Common examples are violin strings, chalk on blackboard, water-lubricated rubber stern tube ship bearings at low speed, squeaky hinges, and oscillating rolling element bearings, especially if they are supporting large flexible structures such as radar antennas. Control requires the introduction of fluid film bearings, viscous seals, or viscous dampers into the system with sufficient positive damping to override the effects of negative damping.

Under moderate pressures, the frictional force is proportional to the normal load on the rubbing surfaces. It is independent of the pressure per unit area of the surfaces. The direction of the friction force opposing the sliding motion is locally exactly opposite to the local relative velocity. Therefore, it takes very little effort to displace transversally two bodies which have a major direction of relative sliding. This behavior, **compound sliding,** is exploited when easing the extraction of a nail by simultaneously rotating it about its axis, and accounts for the ease with which an automobile may skid on the road or with which a plug gage can be inserted into a hole if it is rotated while being pushed in.

The coefficients of friction for dry surfaces (dry friction) depend on the materials sliding over each other and on the finished condition of the surfaces. With greasy (boundary) lubrication, the coefficients depend both on the materials and conditions of the surfaces and on the lubricants employed.

Coefficients of friction are sensitive to atmospheric dust and humidity, oxide films, surface finish, velocity of sliding, temperature, vibration, and the extent of contamination. In many instances the degree of contamination is perhaps the most important single variable. For example, in Table 3.2.1, values for the static coefficient of friction of steel on steel are listed, and, depending upon the degree of contamination of the specimens, the coefficient of friction varies effectively from ∞ (infinity) to 0.013.

The most effective boundary lubricants are generally those which react chemically with the solid surface and form an adhering film that is attached to the surface with a chemical bond. This action depends upon

Table 3.2.1 Coefficients of Static Friction for Steel on Steel

Test condition	f_0	Ref.
Degassed at elevated temp in high vacuum	∞ (weld on contact)	1
Grease-free in vacuum	0.78	2
Grease-free in air	0.39	3
Clean and coated with oleic acid	0.11	2
Clean and coated with solution of stearic acid	0.013	4

SOURCES: (1) Bowden and Young, *Proc. Roy. Soc.,* 1951. (2) Campbell, *Trans. ASME,* 1939. (3) Tomlinson, *Phil. Mag.,* 1929. (4) Hardy and Doubleday, *Proc. Roy. Soc.,* 1923.

the nature of the lubricant and upon the reactivity of the solid surface. Table 3.2.2 indicates that a fatty acid, such as found in animal, vegetable, and marine oils, reduces the coefficient of friction markedly only if it can react effectively with the solid surface. Paraffin oil is almost completely nonreactive.

Table 3.2.2 Coefficients of Static Friction at Room Temperature

Surfaces	Clean	Paraffin oil	Paraffin oil plus 1% lauric acid	Degree of reactivity of solid
Nickel	0.7	0.3	0.28	Low
Chromium	0.4	0.3	0.3	Low
Platinum	1.2	0.28	0.25	Low
Silver	1.4	0.8	0.7	Low
Glass	0.9		0.4	Low
Copper	1.4	0.3	0.08	High
Cadmium	0.5	0.45	0.05	High
Zinc	0.6	0.2	0.04	High
Magnesium	0.6	0.5	0.08	High
Iron	1.0	0.3	0.2	Mild
Aluminum	1.4	0.7	0.3	Mild

SOURCE: From Bowden and Tabor, "The Friction and Lubrication of Solids," Oxford.

Values in Table 3.2.4 of sliding and static coefficients have been selected largely from investigations where these variables have been very carefully controlled. They are representative values for smooth surfaces. It has been generally observed that sliding friction between hard materials is smaller than that between softer surfaces.

Effect of Surface Films Campbell observed a lowering of the coefficient of friction when oxide or sulfide films were present on metal surfaces (*Trans. ASME,* 1939; footnotes to Table 3.2.4). The reductions listed in Table 3.2.3 were obtained with oxide films formed by heating in air at temperatures from 100 to 500°C, and sulfide films produced by immersion in a 0.02 percent sodium sulfide solution.

Table 3.2.3 Static Coefficient of Friction f_0

	Clean and dry	Oxide film	Sulfide film
Steel-steel	0.78	0.27	0.39
Brass-brass	0.88		0.57
Copper-copper	1.21	0.76	0.74

Effect of Sliding Velocity It has generally been observed that coefficients of friction reduce on dry surfaces as sliding velocity increases. (See results of railway brake-shoe tests below.) Dokos measured this reduction in friction for mild steel on medium steel. Values are for the average of four tests with high contact pressures (*Trans. ASME,* 1946; see footnotes to Table 3.2.4).

Sliding velocity, in/s	0.0001	0.001	0.01	0.1	1	10	100
f	0.53	0.48	0.39	0.31	0.23	0.19	0.18

Effect of Surface Finish The degree of surface roughness has been found to influence the coefficient of friction. Burwell evaluated this effect for conditions of boundary or greasy friction (*Jour. SAE,* 1942; see footnotes to Table 3.2.4). The values listed in Table 3.2.5 are for sliding coefficients of friction, hard steel on hard steel. The friction coefficient and wear rates of **polymers against metals** are often lowered by decreasing the surface roughness. This is particularly true of composites such as those with polytetrafluoroethylene (PTFE) which function through transfer to the counterface.

Solid Lubricants In certain applications solid lubricants are used successfully. Boyd and Robertson with pressures ranging from 50,000 to 400,000 lb/in^2 (344,700 to 2,757,000 kN/m^2) found sliding coefficients of friction *f* for hard steel on hard steel as follows: powdered mica, 0.305; powdered soapstone, 0.306; lead iodide, 0.071; silver sulfate, 0.054; graphite, 0.058; molybdenum disulfide, 0.033; tungsten disulfide, 0.037; stearic acid, 0.029 (*Trans. ASME,* 1945; see footnotes to Table 3.2.4).

Coefficients of Static Friction for Special Cases

Masonry and Earth Dry masonry on brickwork, 0.6 to 0.7; timber on polished stone, 0.40; iron on stone, 0.3 to 0.7; masonry on dry clay, 0.51; masonry on moist clay, 0.33.

Earth on Earth Dry sand, clay, mixed earth, 0.4 to 0.7; damp clay, 1.0; wet clay, 0.31; shingle and gravel, 0.8 to 1.1.

Natural Cork On cork, 0.59; on pine with grain, 0.49; on glass, 0.52; on dry steel, 0.45; on wet steel, 0.69; on hot steel, 0.64; on oiled steel, 0.45; water-soaked cork on steel, 0.56; oil-soaked cork on steel, 0.42.

Coefficients of Sliding Friction for Special Cases

Soapy Wood Lesley gives for wood on wood, copiously lubricated with tallow, stearine, and soft soap (as used in launching practice), a starting coefficient of friction equal to 0.036, diminishing to an average value of 0.019 for the first 50 ft of motion of the ship. Rennie gives 0.0385 for wood on wood, lubricated with soft soap, under a load of 56 lb/in^2.

Asbestos-Fabric Brake Material The coefficient of sliding friction *f* of asbestos fabric against a cast-iron brake drum, according to Taylor and Holt (*NBS,* 1940) is 0.35 to 0.40 when at normal temperature. It drops somewhat with rise in brake temperature up to 300°F (149°C). With a further increase in brake temperature from 300 to 500°F (149 to 260°C) the value of *f* may show an increase caused by disruption of the brake surface.

Steel Tires on Steel Rails (Galton)

Speed, mi/h	Start	6.8	13.5	27.3	40.9	54.4	60
Values of *f*	0.242	0.088	0.072	0.07	0.057	0.038	0.027

Railway Brake Shoes on Steel Tires Galton and Westinghouse give, for cast-iron brakes, the following values for *f*, which decrease rapidly with the speed of the rim; the coefficient *f* decreases also with time, as the temperature of the shoe increases.

Speed, mi/h	10	20	30	40	50	60
f, when brakes were applied	0.32	0.21	0.18	0.13	0.10	0.06
f, after 5 s	0.21	0.17	0.11	0.10	0.07	0.05
f, after 12 s		0.13	0.10	0.08	0.06	0.05

Schmidt and Schrader confirm the marked decrease in the coefficient of friction with the increase of rim speed. They also show an irregular slight decrease in the value of *f* with higher shoe pressure on the wheel, but they did not find the drop in friction after a prolonged application of the brakes. Their observations are as follows:

Speed, mi/h	20	30	40	50	60
Coefficient of friction	0.25	0.23	0.19	0.17	0.16

Friction of Steel on Polymers A useful list of friction coefficients between steel and various polymers is given in Table 3.2.6.

Grindstones The coefficient of friction between coarse-grained sandstone and cast iron is $f = 0.21$ to 0.24; for steel, 0.29; for wrought iron, 0.41 to 0.46, according as the stone is freshly trued or dull; for fine-grained sandstone (wet grinding) $f = 0.72$ for cast iron, 0.94 for steel, and 1.0 for wrought iron.

Honda and Yamada give $f = 0.28$ to 0.50 for carbon steel on emery, depending on the roughness of the wheel.

Table 3.2.4 Coefficients of Static and Sliding Friction

Table 3.2.5 Coefficient of Friction of Hard Steel on Hard Steel

	Surface					
	Superfinished	Ground	Ground	Ground	Ground	Grit-blasted
Roughness, microinches	2	7	20	50	65	55
Mineral oil	0.128	0.189	0.360	0.372	0.378	0.212
Mineral oil + 2% oleic acid	0.116	0.170	0.249	0.261	0.230	0.164
Oleic acid	0.099	0.163	0.195	0.222	0.238	0.195
Mineral oil + 2% sulfonated sperm oil	0.095	0.137	0.175	0.251	0.197	0.165

Table 3.2.6 Coefficient of Friction of Steel on Polymers
Room temperature, low speeds.

Material	Condition	*f*
Nylon	Dry	0.4
Nylon	Wet with water	0.15
Plexiglas	Dry	0.5
Polyvinyl chloride (PVC)	Dry	0.5
Polystyrene	Dry	0.5
Low-density (LD) polyethylene, no plasticizer	Dry	0.4
LD polyethylene, no plasticizer	Wet	0.1
High-density (HD) polyethylene, no plasticizer	Dry or wet	0.15
Soft wood	Natural	0.25
Lignum vitae	Natural	0.1
PTFE, low speed	Dry or wet	0.06
PTFE, high speed	Dry or wet	0.3
Filled PTFE (15% glass fiber)	Dry	0.12
Filled PTFE (15% graphite)	Dry	0.09
Filled PTFE (60% bronze)	Dry	0.09
Polyurethane rubber	Dry	1.6
Isoprene rubber	Dry	3–10
Isoprene rubber	Wet (water and alcohol)	2–4

Rubber Tires on Pavement Arnoux gives $f = 0.67$ for dry macadam, 0.71 for dry asphalt, and 0.17 to 0.06 for soft, slippery roads. For a cord tire on a sand-filled brick surface in fair condition. Agg (*Bull.* 88, *Iowa State College Engineering Experiment Station,* 1928) gives the following values of *f* depending on the inflation of the tire:

Inflation pressure, lb/in²	Dry pavement		Wet pavement	
	Static f_0	Sliding *f*	Static f_0	Sliding *f*
40	0.90	0.85	0.74	0.69
50	0.88	0.84	0.64	0.58
60	0.80	0.76	0.63	0.56

Tests of the Goodrich Company on wet brick pavement with tires of different treads gave the following values of *f*:

	Coefficients of friction			
	Static (before slipping)		Sliding (after slipping)	
Speed, mi/h	5	30	5	30
Smooth tire	0.49	0.28	0.43	0.26
Circumferential grooves	0.58	0.42	0.52	0.36
Angular grooves at 60°	0.75	0.55	0.70	0.39
Angular grooves at 45°	0.77	0.55	0.68	0.44

Development continues using various manufacturing techniques (bias ply, belted, radial, studs), tread patterns, and rubber compounds, so that it is not possible to present average values applicable to present conditions.

Sleds For **unshod wooden runners** on smooth wood or stone surfaces, $f = 0.07$ (0.15) when tallow (dry soap) is used as a lubricant (= 0.38 when not lubricated); on snow and ice, $f = 0.035$. For **runners**

with metal shoes on snow and ice, $f = 0.02$. Rennie found for steel on ice, $f = 0.014$. However, as the temperature falls, the coefficient of friction will get larger. Bowden cites the following data for brass on ice:

Temperature, °C	f
0	0.025
−20	0.085
−40	0.115
−60	0.14

ROLLING FRICTION

Rolling is substituted frequently for sliding friction, as in the case of wheels under vehicles, balls or rollers in bearings, rollers under skids when moving loads; frictional resistance to the rolling motion is substantially smaller than to sliding motion. The fact that a resistance arises to rolling motion is due to several factors: (1) the contacting surfaces are elastically deflected, so that, on the finite size of the contact, relative sliding occurs, (2) the deflected surfaces dissipate energy due to internal friction (hysteresis), (3) the surfaces are imperfect so that contact takes place on asperities ahead of the line of centers, and (4) surface adhesion phenomena. The coefficient of rolling friction $f_r = P/L$ where L is the load and P is the frictional resistance.

The frictional resistance P to the rolling of a cylinder under a load L applied at the center of the roller (Fig. 3.2.5) is inversely proportional to the radius r of the roller; $P = (k/r)L$. Note that k has the dimensions of length. Quite often k increases with load, particularly for cases involving

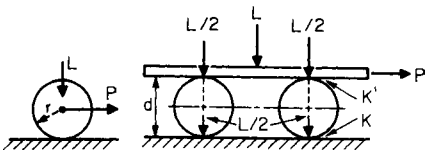

Fig. 3.2.5

plastic deformations. Values of k, in inches, are as follows: hardwood on hardwood, 0.02; iron on iron, steel on steel, 0.002; hard polished steel on hard polished steel, 0.0002 to 0.0004.

Data on rolling friction are scarce. Noonan and Strange give, for steel rollers on steel plates and for loads varying from light to those causing a permanent set of the material, the following values of k, in inches: surfaces well finished and clean, 0.0005 to 0.001; surfaces well oiled, 0.001 to 0.002; surfaces covered with silt, 0.003 to 0.005; surfaces rusty, 0.005 to 0.01.

If a load L is moved on rollers (Fig. 3.2.5) and if k and k' are the respective coefficients of friction for the lower and upper surfaces, the frictional force $P = (k + k')L/d$.

McKibben and Davidson (*Agri. Eng.,* 1939) give the data in Table 3.2.7 on the rolling resistance of various types of wheels for typical road and field conditions. Note that the coefficient f_r is the ratio of resistance force to load.

Moyer found the following average values of f_r for pneumatic rubber tires properly inflated and loaded: hard road, 0.008; dry, firm, and well-packed gravel, 0.012; wet loose gravel, 0.06.

FRICTION OF MACHINE ELEMENTS

Work of Friction—Efficiency In a simple machine or assemblage of two elements, the work done by an applied force P acting through the distance s is measured by the product Ps. The useful work done is less and is measured by the product Ll of the resistance L by the distance l through which it acts. The **efficiency** e of the machine is the ratio of the useful work performed to the total work received, or $e = Ll/Ps$. The **work expended in friction** W_f is the difference between the total work received and the useful work, or $W_f = Ps - Ll$. The lost-work ratio $= V = W_f/Ll$, and $e = 1/(1 + V)$.

If a machine consists of a train of mechanisms having the respective efficiencies $e_1, e_2, e_3 \ldots e_n$, the combined efficiency of the machine is equal to the product of these efficiencies.

Efficiencies of Machines and Machine Elements The values for machine elements in Table 3.2.8 are from "Elements of Machine Design," by Kimball and Barr. Those for machines are from Goodman's "Mechanics Applied to Engineering." The quantities given are percentage efficiencies.

Wedges

Sliding in V Guides If a wedge-shaped slide having an angle $2b$ is pressed into a V guide by a force P (Fig. 3.2.6), the total force normal to the wedge faces will be $N = P/\sin b$. A friction force F, opposing motion along the longitudinal axis of the wedge, arises by virtue of the coefficient of friction f between the contacting surface of the wedge and guides: $F = fN = fP/\sin b$. In these formulas, the fact that the elasticity of the materials permits an advance of the wedge into the guide under the load P has been neglected. The common efficiency for V guides is $e = 0.88$ to 0.90.

Table 3.2.7 Coefficients of Rolling Friction f_r for Wheels with Steel and Pneumatic Tires

Wheel	Inflation press, lb/in²	Load, lb	Concrete	Bluegrass sod	Tilled loam	Loose sand	Loose snow 10–14 in deep
2.5 × 36 steel		1,000	0.010	0.087	0.384	0.431	0.106

Thread angle, 15°	75–90
Belting	96–98
Pin-connected chains (bicycle)	95–97
High-grade transmission chains	97–99
Weston pulley block (½ ton)	30–47
Epicycloidal pulley block	40–45
1-ton steam hoist or windlass	50–70
Hydraulic windlass	60–80
Hydraulic jack	80–90
Cranes (steam)	60–70
Overhead traveling cranes	30–50
Locomotives (drawbar hp/ihp)	65–75
Hydraulic couplings, max	98

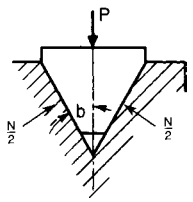

Fig. 3.2.6

Taper Keys In Fig. 3.2.7 if the key is moved in the direction of the force P, the force H must be overcome. The supporting reactions K_1, K_2, and K_3 together with the required force P may be obtained by drawing the force polygon (Fig. 3.2.8). The friction angles of these faces are a_1, a_2, and a_3, respectively. In Fig. 3.2.8, draw AB parallel to H in Fig. 3.2.7, and lay it off to scale to represent H. From the point A, draw AC

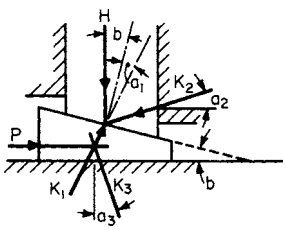

Fig. 3.2.7

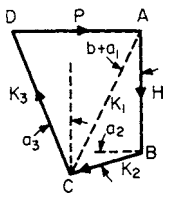

Fig. 3.2.8

parallel to K_1, i.e., making the angle $b + a_1$ with AB; from the other extremity of AB, draw BC parallel to K_2 in Fig. 3.2.7. AC and CB then give the magnitudes of K_1 and K_2, respectively. Now through C draw CD parallel to K_3 to its intersection with AD which has been drawn through A parallel to P. The magnitudes of K_3 and P are then given by the lengths of CD and DA.

By calculation,

$$K_1/H = \cos a_2/\cos (b + a_1 + a_2)$$
$$P/K_1 = \sin (b + a_1 + a_3)/\cos a_3$$
$$P/H = \cos a_2 \sin (b + a_1 + a_3)/\cos a_3 \cos (b + a_1 + a_2)$$

If $a_1 = a_2 = a_3 = a$, then $P = H \tan (b + 2a)$, and efficiency $e = \tan b/\tan (b + 2a)$. Force required to loosen the key $= P_1 = H \tan (2a - b)$. In order for the key not to slide out when force P is removed, it is necessary that $b < (a_1 + a_3)$, or $b < 2a$.

The forces acting upon the taper key of Fig. 3.2.9 may be found in a similar way (see Fig. 3.2.10).

$$P = 2H \cos a \sin (b + a)/\cos (b + 2a)$$
$$= 2H \tan (b + a)/[1 - \tan a \tan (b + a)]$$
$$= 2H \tan (b + a) \text{ approx}$$

The force to loosen the key is $P_1 = 2H \tan (a - b)$ approx, and the efficiency $e = \tan b/\tan (b + a)$. The key will be self-locking when $b < a$, or, more generally, when $2b < (a_1 + a_3)$.

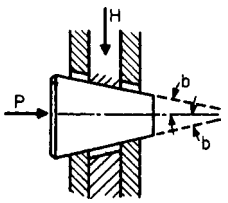

Fig. 3.2.9

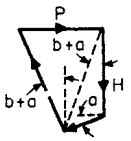

Fig. 3.2.10

Screws

Screws with Square Threads (Fig. 3.2.11) Let r = mean radius of the thread = ½ (radius at root + outside radius), and l = pitch (or lead of a single-threaded screw), both in inches; b = angle of inclination of thread to a plane at right angles to the axis of screw ($\tan b = l/2\pi r$); and f = coefficient of sliding friction = $\tan a$. Then for a screw in uniform motion (friction of the root and outside surfaces being neglected) there is required a force P acting at right angles to the axis at the distance r. $P = L \tan (b \pm a) = L(l \pm 2\pi rf)/(2\pi r \pm fl)$, where the upper signs are for motion in a direction opposed to that of L and the lower for motion in the same direction as that of L. When $b \leq a$, the screw will not "overhaul" (or move under the action of the load L).

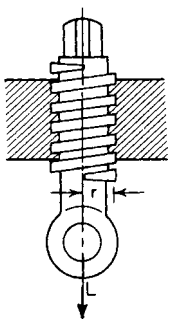

Fig. 3.2.11

The **efficiency** for motion opposed to direction in which L acts = $e = \tan b/\tan(b + a)$; for motion in the same direction in which L acts, $e = \tan (b - a)/\tan b$.

The value of e is a maximum when $b = 45° - ½a$; e.g., $e_{max} = 0.81$ for $b = 42°$ and $f = 0.1$. Since e increases rapidly for values of b up to 20°, this angle is generally not exceeded; for $b = 20°$, and $f_1 = 0.10$, $e = 0.74$. In presses, where the mechanical advantage is required to be great, b is taken down to 3°, for which value $e = 0.34$ with $f = 0.10$.

Kingsbury found for square-threaded screws running in loose-fitting nuts, the following coefficients of friction: lard oil, 0.09 to 0.25; heavy mineral oil, 0.11 to 0.19; heavy oil with graphite, 0.03 to 0.15.

Ham and Ryan give for screws the following values of coefficients of friction, with medium mineral oil: high-grade materials and workmanship, 0.10; average quality materials and workmanship, 0.12; poor workmanship, 0.15. The use of castor oil as a lubricant lowered f from 0.10 to 0.066. The coefficients of static friction (at starting) were 30 percent higher. Table 3.2.8 gives representative values of efficiency.

Screws with V Threads (Fig.3.2.12) Let c = half the angle between the faces of a thread. Then, using the same notation as for squarethreaded screws, for a screw in motion (neglecting friction of root and outside surfaces),

$$P = L(l \pm 2\pi rf \sec d)/(2\pi r \pm lf \sec d)$$

d is the angle between a plane normal to the axis of the screw through the point of the resultant thread friction, and a plane which is tangent to

the surface of the thread at the same point (see Groat, *Proc. Engs. Soc. West. Penn,* **34**). Sec $d = \sec c\sqrt{1 - (\sin b \sin c)^2}$. For small values of b this reduces practically to sec d = sec c, and, for all cases the approximation, $P = L(l \pm 2\pi rf \sec c)/(2\pi r \pm lf \sec c)$ is within the limits of probable error in estimating values to be used for f.

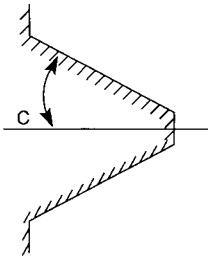

Fig. 3.2.12

The **efficiencies** are: $e = \tan b(1 - f \tan b \sec d)/(\tan b + f \sec d)$ for motion opposed to L, and $e = (\tan b - f \sec d)/\tan b(1 + f \tan b \sec d)$ for motion with L. If we let $\tan d' = f \sec d$, these equations reduce, respectively, to $e = \tan b/\tan (b + d')$ and $e = \tan (b - d')/\tan b$. Negative values in the latter case merely mean that the thread will not overhaul. Subtract the values from unity for actual efficiency, considering the external moment and not the load L as being the driver. The efficiency of a V thread is lower than that of a square thread of the same helix angle, since $d' > a$.

For a **V-threaded screw and nut,** let r_1 = outside radius of thread, r_2 = radius at root of thread, $r = (r_1 + r_2)/2$, $\tan d' = f \sec d$, r_0 = mean radius of nut seat = $1.5r$ (approx) and f' = coefficient of friction between nut and seat.

To tighten up the nut the turning moment required is $M = Pr + Lr_0 f = Lr[\tan (d' + b) + 1.5f']$. **To loosen** $M = Lr[\tan (d' - b) + 1.5f']$.

The **total tension in a bolt** due to tightening up with a moment M is $T = 2\pi M/(l + fl \sec b \sec d \operatorname{cosec} b + f' 3\pi r)$. $T \div$ area at root gives unit pure tensile stress induced, S_t. There is also a unit torsional stress: $S_s = 2(M - 1.5rf'T)/\pi r_2^3$. The equivalent combined stress is $S = 0.35S_t + 0.65\sqrt{S_t^2 + 4S_s^2}$.

Kingsbury, from tests on U.S. standard bolts, finds efficiencies for tightening up nuts from 0.06 to 0.12, depending upon the roughness of the contact surfaces and the character of the lubrication.

Toothed and Worm Gearing

The efficiency of **spur and bevel gearing** depends on the material and the workmanship of the gears and on the lubricant employed. For high-speed gears of good quality the efficiency of the gear transmission is 99 percent; with slow-speed gears of average workmanship the efficiency of 96 percent is common. On the average, efficiencies of 97 to 98 percent can be considered normal.

In **helical gears,** where considerable transverse sliding of the meshing teeth on each other takes place, the friction is much greater. If b and c are, respectively, the spiral angles of the teeth of the driving and driven helical gears (i.e., the angle between the teeth and the axis of rotation), $b + c$ is the shaft angle of the two gears, and $f = \tan a$ is the coefficient of sliding friction of the teeth, the efficiency of the gear transmission is $e = [\cos b \cos (c + a)]/[\cos c \cos (b - a)]$.

In the case of **worm gearing** when the shafts are normal to each other ($b + c = 90$), the efficiency is $e = \tan c/\tan (c + a) = (1 - pf/2\pi r)/(1 + 2\pi rf/p)$, where c is the spiral angle of the worm wheel, or the lead angle of the worm; p the lead, or pitch of the worm thread; and r the mean radius of the worm. Typical values of f are shown in Table 3.2.9.

Journals and Bearings

Friction of Journal Bearings If P = total load on journal, l = journal length, and $2r$ = journal diameter, then $p = P/2rl$ = mean normal pressure on the projected area of the journal. Also, if f_1 is the **coefficient of journal friction,** the **moment of journal friction** for a cylindrical journal is $M = f_1 Pr$. The **work expended in friction** at angular velocity ω is

$$W_f = \omega M = f_1 Pr\omega$$

For the **conical bearing** (Fig. 3.2.13) the mean radius $r_m = (r + R)/2$ is to be used.

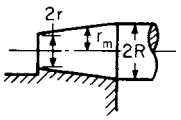

Fig. 3.2.13

Values of Coefficient of Friction For very low velocities of rotation (e.g., below 10 r/min), high loads, and with good lubrication, the coefficient of friction approaches the value of greasy friction, 0.07 to 0.15 (see Table 3.2.4). This is also the "pullout" coefficient of friction *on starting* the journal. With higher velocities, a fluid film is established between the journal and bearing, and the values of the coefficient of friction depend on the speed of rotation, the pressure on the bearing, and the viscosity of the oil. For journals running in complete bearing bushings, with a small clearance, i.e., with the diameter of the bushing slightly larger than the diameter of the journal, the experimental data of McKee give approximate values of the coefficient of friction as in Fig. 3.2.14.

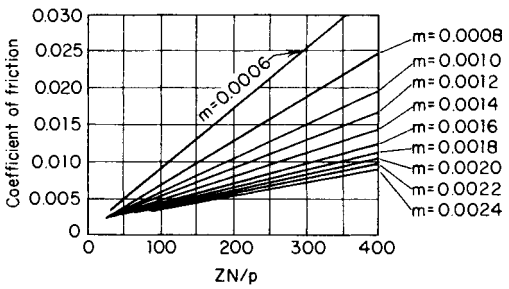

Fig. 3.2.14 Coefficient of friction of journal.

If d_1 is the diameter of the bushing in inches, d the diameter of the journal in inches, then $(d_1 - d)$ is the diametral clearance and $m = (d_1 - d)/d$ is the clearance ratio. The diagram of McKee (Fig. 3.2.14) gives the coefficient of friction as a function of the characteristic number

Table 3.2.9 Coefficients of Friction for Worm Gears

Rubbing speed of worm, ft/min (m/min)	100 (30.5)	200 (61)	300 (91.5)	500 (152)	800 (244)	1200 (366)
Phosphor-bronze wheel, polished-steel worm	0.054	0.045	0.039	0.030	0.024	0.020
Single-threaded cast-iron worm and gear	0.060	0.051	0.047	0.034	0.025	

ZN/p, where N is the speed of rotation in revolutions per minute, $p = P/(dl)$ is the average pressure in lb/in^2 on the projected area of the bearing, P is the load, l is the axial length of the bearing, and Z is the absolute viscosity of the oil in centipoises. Approximate values of Z at 100 (130)°F are as follows: light machine oil, 30 (16); medium machine oil, 60 (25); medium-heavy machine oil, 120 (40); heavy machine oil, 160 (60).

For purposes of design of ordinary machinery with bearing pressures from 50 to 300 lb/in^2 (344.7 to 2,068 kN/m^2) and speeds of 100 to 3,000 rpm, values for the coefficient of journal friction can be taken from 0.008 to 0.020.

Thrust Bearings

Frictional Resistance for Flat Ring Bearing Step bearings or pivots may be used to resist the end thrust of shafts. Let L = total load in the direction of the shaft axis and f = coefficient of sliding friction.

For a **ring-shaped flat step bearing** such as that shown in Fig. 3.2.15 (or a **collar bearing**), the **moment of thrust friction** $M = \frac{1}{3}fL(D^3 - d^3)/(D^2 - d^2)$. For a **flat circular step bearing,** $d = 0$, and $M = \frac{1}{3}fLD$.

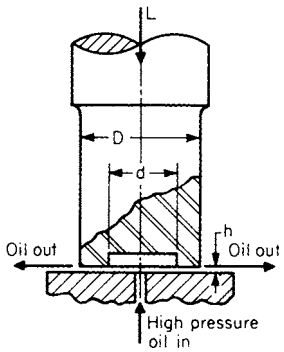

Fig. 3.2.15

The value of the coefficient of sliding friction is 0.08 to 0.15 when the speed of rotation is very slow. At higher velocities when a collar or step bearing is used, $f = 0.04$ to 0.06. If the design provides for the formation of a load carrying oil film, as in the case of the Kingsbury thrust bearing, the coefficient of friction has values $f = 0.001$ to 0.0025.

Where oil is supplied from an external pump with such pressure as to separate the surfaces and provide an oil film of thickness h (Fig. 3.2.15), the frictional moment is

$$M = \frac{Zn(D^4 - d^4)}{67 \times 10^7 h} = \frac{\pi\mu\omega(D^4 - d^4)}{32\,h}$$

where D and d are in inches, μ is the absolute viscosity, ω is the angular velocity, h is the film thickness, in, Z is viscosity of lubricant in centipoises, and n is rotation speed, r/min. With this kind of lubrication the frictional moment depends upon the speed of rotation of the shaft and actually approaches zero for zero shaft speeds. The thrust load will be carried on a film of oil regardless of shaft rotation for as long as the pump continues to supply the required volume and pressure (see also Secs. 8 and 14).

EXAMPLE. A hydrostatic thrust bearing carries 101,000 lb, D is 16 in, d is 10 in, oil-film thickness h is 0.006 in, oil viscosity Z, 30 centipoises at operating temperature, and n is 750 r/min. Substituting these values, the frictional torque M is 310 in · lb (358 cm · kg). The oil supply pressure was 82.5 lb/in^2 (569 kN/m^2); the oil flow, 12.2 gal/min (46.2 l/min).

Frictional Forces in Pin Joints of Mechanisms

In the absence of friction, or when the effect of friction is negligible, the force transmitted by the link b from the driver a to the driven link c (Figs. 3.2.16 and 3.2.17) acts through the centerline OO of the pins connecting the link b with links a and c. With friction, this line of action shifts to the line AA, tangent to small circles of diameter d. The diameter d of the circle, called the **friction circle,** for each individual joint, is equal to fD, where D is the diameter of the pin and f is the coefficient of friction between the pin and the link. The choice of the proper disposition of the tangent AA with respect to the two friction circles is dictated

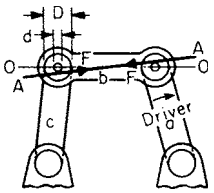

Fig. 3.2.16

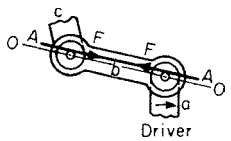

Fig. 3.2.17

by the consideration that friction always opposes the action of the linkage. The force f opposes the motion of a; therefore, with friction it acts on a longer lever than without friction (Figs. 3.2.16 and 3.2.17). On the other hand, the force F drives the link c; friction hinders its action, and the equivalent lever is shorter with friction than without friction; the friction throws the line of action toward the center of rotation of link c.

EXAMPLE. An engine eccentric (Fig. 3.2.18) is a joint where the friction loss may be large. For the dimensions shown and with a torque of 250 in · lb applied to the rotating shaft, the resultant horizontal force, with no friction, will act through the center of the eccentric and be 250/(2.5 sin 60) or 115.5 lb. With friction coefficient 0.1, the resultant force (which for a long rod remains approximately horizontal) will be tangent to the friction circle of radius 0.1 × 5, or 0.5 in, and have a magnitude of 250/(2.5 sin 60 + 0.5), or 93.8 lb (42.6 kg).

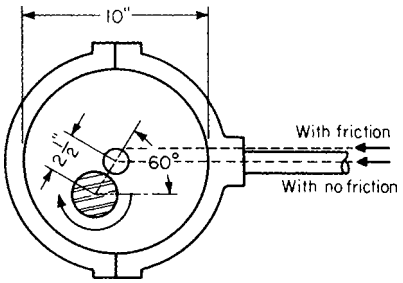

Fig. 3.2.18

Tension Elements

Frictional Resistance In Fig. 3.2.19, let T_1 and T_2 be the tensions with which a rope, belt, chain, or brake band is strained over a drum, pulley, or sheave, and let the rope or belt be on the point of slipping from T_2 toward T_1 by reason of the difference of tension $T_1 - T_2$. Then $T_1 - T_2$ = circumferential force P transferred by friction must be equal

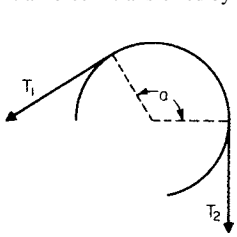

Fig. 3.2.19

to the frictional resistance W of the belt, rope, or band on the drum or pulley. Also, let a = angle subtending the arc of contact between the drum and tension element. Then, disregarding centrifugal forces,

$$T_1 = T_2 e^{fa} \text{ and } P = (e^{fa} - 1)T_1/e^{fa} = (e^{fa} - 1)T_2 = W$$

where e = base of the napierian system of logarithms = 2.178 +.

Table 3.2.10 Values of e^{fa}

NOTE: $e^{\pi} = 23.1407$, $\log e^{\pi} = 1.3643764$.

f is the static coefficient of friction (f_0) when there is no slip of the belt or band on the drum and the coefficient of kinetic friction (f) when slip takes place. For ease of computation, the values of the quantity e^{fa} are tabulated on Table 3.2.10.

Average values of f_0 for belts, ropes, and brake bands are as follows: for leather belt on cast-iron pulley, very greasy, 0.12; slightly greasy, 0.28; moist, 0.38. For hemp rope on cast-iron drum, 0.25; on wooden drum, 0.40; on rough wood, 0.50; on polished wood, 0.33. For iron brake bands on cast-iron pulleys, 0.18. For wire ropes, Tichvinsky reports coefficients of static friction, f_0, for a $\frac{5}{8}$ rope (8 × 19) on a worn-in cast-iron groove: 0.113 (dry); for mylar on aluminum, 0.4 to 0.7.

Belt Transmissions; Effects of Belt Compliance

In the configuration of Fig. 3.2.20, pulley A drives a belt at angular velocity ω_A. Pulley B, here assumed to be of the same radius R as A, is driven at angular velocity ω_B. If the belt is extensible and the resistive torque $M = (T_1 - T_2)\,R$ is applied at B, ω_B will be smaller than ω_A and power will be dissipated at a rate $W = M(\omega_A - \omega_B)$. Likewise, the surface velocity V_1 of the more stretched belt will be larger than V_2. No slip will take place over the wraps A_T-A_S and B_T-B_S. The slip angles a_A and a_B can be calculated from

$$a_A = [\ln (T_1/T_2)]/f_A \qquad a_B = [\ln (T_1/T_2)]/f_B$$

where f_A and f_B are the coefficients of friction on pulleys A and B, respectively. To calculate the above values, it is necessary to know the mean tension of the belt, $T = (T_1 + T_2)/2$. Then, $T_1/T_2 = [T + M/(2R)]/[T - M/(2R)]$. In this configuration, when the slip angles become equal to π (180°), complete slip occurs.

It is interesting to note that torque is transmitted only over the slip arcs a_A and a_B since there is no tension variation in the arcs A_T-A_S and B_T-B_S where the belt is in a uniform state of stretch.

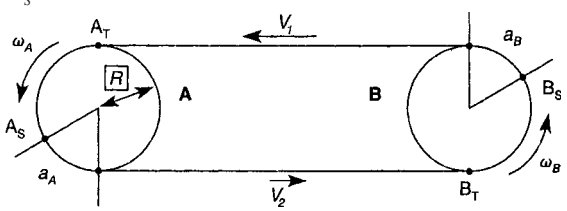

Fig. 3.2.20 Pulley transmission with extensible belt.

$\mathbf{C}$ = Cauchy number
$\mathbf{C}_p$ = pressure coefficient
d = diameter, distance
E = bulk modulus of elasticity, modulus of elasticity (Young's modulus), velocity of approach factor, specific energy
$\mathbf{E}$ = Euler number
f = frequency, friction factor
F = dimension of force, force
$\mathbf{F}$ = Froude number
g = acceleration due to gravity
g_c = proportionality constant = 32.1740 lbm/(lbf) (ft/s^2)
G = mass velocity
h = head, vertical distance below a liquid surface
H = geopotential altitude
i = ideal
I = moment of inertia
J = mechanical equivalent of heat, 778.169 ft · lbf
k = isentropic exponent, ratio of specific heats
K = constant, resistant coefficient, weir coefficient
$\mathbf{K}$ = flow coefficient
L = dimension of length, length
m = mass, lbm
$\dot{m}$ = mass rate of flow, lbm/s
M = dimension of mass, mass (slugs)
$\dot{M}$ = mass rate of flow, slugs/s
$\mathbf{M}$ = Mach number
n = exponent for a polytropic process, roughness factor
N = dimensionless number
p = pressure
P = perimeter, power
q = heat added
$\mathbf{q}$ = flow rate per unit width
Q = volumetric flow rate
r = pressure ratio, radius
R = gas constant, reactive force
$\mathbf{R}$ = Reynolds number
R_h = hydraulic radius
s = distance, second
sp. gr. = specific gravity
S = scale reading, slope of a channel
$\mathbf{S}$ = Strouhal number
t = time
T = dimension of time, absolute temperature
u = internal energy
U = stream-tube velocity
v = specific volume
V = one-dimensional velocity, volume
$\mathbf{V}$ = velocity ratio
W = work done by fluid
$\mathbf{W}$ = Weber number
x = abscissa
y = ordinate
Y = expansion factor
z = height above a datum
Z = compressibility factor, crest height
α = angle, kinetic energy correction factor
β = ratio of primary element diameter to pipe diameter
γ = specific weight
δ = boundary-layer thickness
ε = absolute surface roughness
θ = angle
μ = dynamic viscosity
ν = kinematic viscosity
π = 3.14159 . . . , dimensionless ratio
ρ = density
σ = surface tension
τ = unit shear stress
ω = rotational speed

FLUIDS AND OTHER SUBSTANCES

Substances may be classified by their response when at rest to the imposition of a shear force. Consider the two very large plates, one moving, the other stationary, separated by a small distance y as shown in Fig. 3.3.1. The space between these plates is filled with a substance whose surfaces adhere to these plates in such a manner that its upper surface moves at the same velocity as the upper plate and the lower surface is stationary. The upper surface of the substance attains a velocity of U as the result of the application of shear force F_s. As y approaches dy, U approaches dU, and the rate of deformation of the substance becomes dU/dy. The **unit shear stress** is defined by $\tau = F_s/A_s$, where A_s is the shear or surface area. The deformation characteristics of various substances are shown in Fig. 3.3.2.

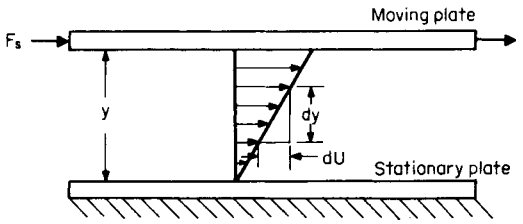

Fig. 3.3.1 Flow of a substance between parallel plates.

An ideal or **elastic solid** will resist the shear force, and its rate of deformation will be zero regardless of loading and hence is coincident with the ordinate of Fig. 3.3.2. A **plastic** will resist the shear until its yield stress is attained, and the application of additional loading will cause it to deform continuously, or flow. If the deformation rate is directly proportional to the flow, it is called an **ideal plastic.**

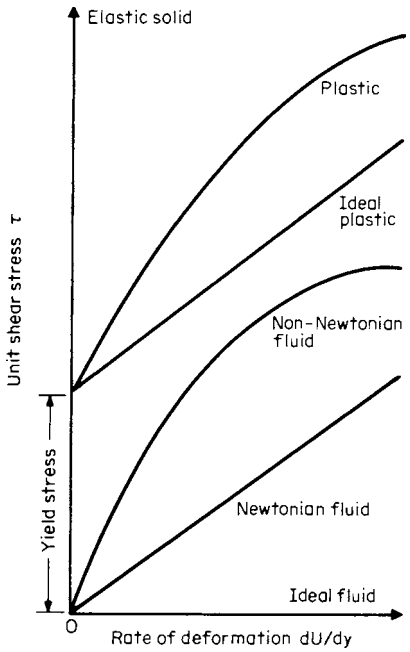

Fig. 3.3.2 Deformation characteristics of substances.

If the **substance** is unable to resist even the slightest amount of shear without flowing, it is a **fluid.** An **ideal fluid** has no internal friction, and hence its deformation rate coincides with the abscissa of Fig. 3.3.2. All real fluids have internal friction so that their rate of deformation is proportional to the applied shear stress. If it is directly proportional, it is called a **Newtonian fluid;** if not, a **non-Newtonian fluid.**

Two kinds of **fluids** are considered in this section, incompressible and compressible. A **liquid** except at very high pressures and/or temperatures may be considered incompressible. **Gases** and **vapors** are compressible fluids, but only **ideal gases** (those that follow the ideal-gas laws) are considered in this section. All others are covered in Secs. 4.1 and 4.2.

FLUID PROPERTIES

The **density** ρ of a fluid is its mass per unit volume. Its dimensions are M/L^3. In **fluid mechanics,** the units are slugs/ft^3 and lbf · s^2/ft^4 (515.3788 kg/m^3), but in **thermodynamics** (Sec. 4.1), the units are lbm/ft^3 (16.01846 kg/m^3). Numerical values of densities for selected liquids are shown in Table 3.3.1. The temperature change at 68°F (20°C) required to produce a 1 percent change in density varies from 12°F (6.7°C) for kerosene to 99°F (55°C) for mercury.

The **specific volume** v of a fluid is its volume per unit mass. Its dimensions are L^3/M. The units are ft^3/lbm. Specific volume is related to density by $v = 1/\rho g_c$, where g_c is the proportionality constant [32.1740 (lbm/lbf)(ft/s^2)]. **Specific volumes** of ideal gases may be computed from the equation of state: $v = RT/p$, where R is the gas constant in ft · lbf/(lbm)(°R) (see Sec. 4.1), T is the temperature in degrees Rankine (°F + 459.67), and p is the pressure in lbf/ft^2 abs.

The **specific weight** γ of a fluid is its weight per unit volume and has dimensions of F/L^3 or $M/(L^2)(T^2)$. The units are lbf/ft^3 or slugs/(ft^2)(s^2) (157.087 N/m^3). Specific weight is related to density by $\gamma = \rho g$, where g is the acceleration of gravity.

The **specific gravity** (sp. gr.) of a substance is a dimensionless ratio of the density of a fluid to that of a reference fluid. Water is used as the reference fluid for solids and liquids, and air is used for gases. Since the density of liquids changes with temperature for a precise definition of **specific gravity,** the temperature of the fluid and the reference fluid should be stated, for example, 60/60°F, where the upper temperature pertains to the liquid and the lower to water. If no temperatures are stated, reference is made to water at its maximum density, which occurs at 3.98°C and atmospheric pressure. The maximum density of water is 1.9403 slugs/ft^3 (999.973 kg/m^3). See Sec. 1.2 for conversion factors for API and Baumé hydrometers. For gases, it is common practice to use the ratio of the molecular weight of the gas to that of air (28.9644), thus eliminating the necessity of stating the pressure and temperature for ideal gases.

The **bulk modulus of elasticity** E of a fluid is the ratio of the pressure stress to the volumetric strain. Its dimensions are F/L^2. The units are lbf/in^2 or lbf/ft^2. E depends upon the thermodynamic process causing the change of state so that $E_x = -v(\partial p/\partial v)_x$, where x is the process. For ideal gases, $E_T = p$ for an isothermal process and $E_s = kp$ for an isentropic process where k is the ratio of specific heats. Values of E_T and E_s for liquids are given in Table 3.3.2. For liquids, a mean value is used by integrating the equation over a finite interval, or $E_{xm} = -v_1(\Delta p/\Delta v)_x = v_1(p_2 - p_1)/(v_1 - v_2)_x$.

EXAMPLE. What pressure must be applied to ethyl alcohol at 68°F (20°C) to produce a 1 percent decrease in volume at constant temperature?

$$\Delta p = -E_T(\Delta v/v) = -(130{,}000)(-0.01)$$
$$= 1{,}300 \text{ lbf/in}^2\ (9 \times 10^6 \text{ N/m}^2)$$

In a like manner, the pressure required to produce a 1 percent decrease in the volume of mercury is found to be 35,900 lbf/in^2 (248 × 10^6 N/m^2). For most engineering purposes, liquids may be considered as incompressible fluids.

The **acoustic velocity,** or velocity of sound in a fluid, is given by $c = \sqrt{E_s/\rho}$. For an ideal gas $c = \sqrt{kp/\rho} = \sqrt{kg_c pv} = \sqrt{kg_c RT}$. Values of the speed of sound in liquids are given in Table 3.3.2.

EXAMPLE. Check the value of the velocity of sound in benzene at 68°F (20°C) given in Table 3.3.2 using the isentropic bulk modulus. $c = \sqrt{E_s/\rho} = \sqrt{144 \times 223{,}000/1.705} = 4{,}340$ ft/s (1,320 m/s). Additional information on the velocity of sound is given in Secs. 4, 11, and 12.

Application of shear stress to a fluid results in the continual and permanent distortion known as flow. **Viscosity** is the resistance of a fluid to shear motion—its internal friction. This resistance is due to two phenomena: (1) cohesion of the molecules and (2) molecular transfer from one layer to another, setting up a tangential or shear stress. In liquids, cohesion predominates, and since cohesion decreases with increasing temperature, the viscosity of liquids does likewise. Cohesion is relatively weak in gases; hence increased molecular activity with increasing temperature causes an increase in molecular transfer with corresponding increase in viscosity.

The **dynamic viscosity** μ of a fluid is the ratio of the shearing stress to the rate of deformation. From Fig. 3.3.1, $\mu = \tau/(dU/dy)$. Its dimensions are $(F)(T)/L^2$ or $M/(L)(T)$. The units are lbf · s/ft^2 or slugs/(ft)(s) [47.88026(N · s)/m^2].

In the cgs system, the unit of dynamic viscosity is the **poise,** 2,089 × 10^{-6} (lbf · s)/ft^2 [0.1 (N · s)/m^2], but for convenience the **centipoise** (1/100 poise) is widely used. The dynamic viscosity of water at 68°F (20°C) is approximately 1 centipoise.

Table 3.3.3 gives values of dynamic viscosity for selected liquids at atmospheric pressure. Values of viscosity for fuels and lubricants are given in Sec. 6. The effect of pressure on liquid viscosity is generally

[c] "Steam Tables," ASME, 1967.

unimportant in fluid mechanics except in lubricants (Sec. 6). The viscosity of water changes little at pressures up to 15,000 lbf/in^2, but for animal and vegetable oils it increases about 350 percent and for mineral oils about 1,600 percent at 15,000 lbf/in^2 pressure.

The dynamic viscosity of gases is primarily a temperature function and essentially independent of pressure. Table 3.3.4 gives values of dynamic viscosity of selected gases.

The **kinematic viscosity** ν of a fluid is its dynamic viscosity divided by its density, or $\nu = \mu/\rho$. Its dimensions are L^2/T. The units are ft^2/s (9.290304×10^{-2} m^2/s).

In the cgs system, the unit of kinematic viscosity is the **stoke** (1×10^{-4} m^2/s), but for convenience, the **centistoke** (1/100 stoke) is widely used. The kinematic viscosity of water at 68°F (20°C) is approximately 1 centistoke.

The standard device for **experimental determination of kinematic viscosity** in the United States is the **Saybolt Universal** viscometer. It consists essentially of a metal tube and an orifice built to rigid specifications and calibrated. The time required for a gravity flow of 60 cubic centimeters is called the SSU (Saybolt seconds Universal). Approximate conversions of SSU to stokes may be made as follows:

$$32 < \text{SSU} < 100 \text{ seconds, stokes} = 0.00226\,(\text{SSU}) - 1.95/(\text{SSU})$$
$$\text{SSU} > 100 \text{ seconds, stokes} = 0.00220\,(\text{SSU}) - 1.35/(\text{SSU})$$

For viscous oils, the **Saybolt Furol** viscometer is used. Approximate conversions of SSF (Saybolt seconds Furol) may be made as follows:

$$25 < \text{SSF} < 40 \text{ seconds, stokes} = 0.0224\,(\text{SSF}) - 1.84/(\text{SSF})$$
$$\text{SSF} > 40 \text{ seconds, stokes} = 0.0216\,(\text{SSF}) - 0.60/(\text{SSF})$$

For exact conversions of Saybolt viscosities, see ASTM D445–71 and Sec. 6.11.

The **surface tension** σ of a fluid is the work done in extending the surface of a liquid one unit of area or work per unit area. Its dimensions are F/L. The units are lbf/ft (14.5930 N/m).

Values of σ for various interfaces are given in Table 3.3.5. Surface tension decreases with increasing temperature. Surface tension is of importance in the formation of bubbles and in problems involving atomization.

Table 3.3.5 Surface Tension of Liquids at One Atmosphere and 68°F (20°C)

§ In vacuum.

Capillary action is due to surface tension, **cohesion** of the liquid molecules, and the **adhesion** of the molecules on the surface of a solid. This action is of importance in fluid mechanics because of the formation of a meniscus (curved section) in a tube. When the adhesion is greater than the cohesion, a liquid "wets" the solid surface, and the liquid will rise in the tube and conversely will fall if the reverse. Figure 3.3.3 illustrates this effect on manometer tubes. In the reading of a manometer, all data should be taken at the center of the meniscus.

The **vapor pressure** pv of a fluid is the pressure at which its liquid and vapor are in equilibrium at a given temperature. See Secs. 4.1 and 4.2 for further definitions and values.

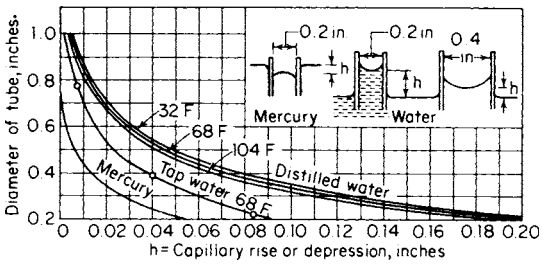

Fig. 3.3.3 Capillarity in circular glass tubes.

FLUID STATICS

Pressure p is the force per unit area exerted on or by a fluid and has dimensions of F/L^2. In fluid mechanics and in thermodynamic equations, the units are lbf/ft^2 (47.88026 N/m^2), but engineering practice is to use units of lbf/in^2 (6,894.757 N/m^2).

The relationship between **absolute pressure, gage pressure,** and **vacuum** is shown in Fig. 3.3.4. Most fluid-mechanics equations and **all** thermodynamic equations require the use of **absolute pressure,** and unless otherwise designated, a pressure should be understood to be **absolute pressure.** Common practice is to denote absolute pressure as lbf/ft^2 abs, or psfa, lbf/in^2 abs or psia; and in a like manner for **gage pressure** lbf/ft^2 g, lbf/in^2 g, and psig.

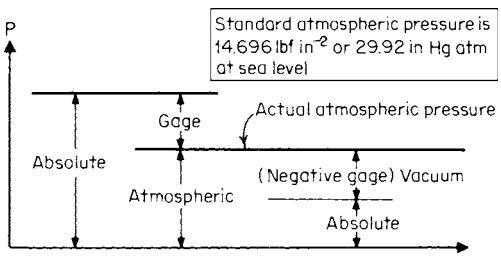

Fig. 3.3.4 Pressure relations.

According to **Pascal's** principle, the pressure in a static fluid is the same in all directions.

The **basic equation of fluid statics** is obtained by consideration of a fluid particle at rest with respect to other fluid particles, all being subjected to body-force accelerations of a_x, a_y, and a_z opposite the directions of x, y, and z, respectively, and the acceleration of gravity in the z direction, resulting in the following:

$$dp = -\rho[a_x\,dx + a_y\,dy + (a_z + g)\,dz]$$

Pressure-Height Relations For a fluid at rest and subject only to the gravitational force, a_x, a_y, and a_z are zero and the **basic equation for fluid statics reduces to** $dp = -\rho g\,dz = \gamma\,dz$.

Liquids (Incompressible Fluids) The pressure-height equation integrates to $(p_1 - p_2) = \rho g(z_2 - z_1) = \gamma(z_2 - z_1) = \Delta p = \gamma h$, where h is measured from the liquid surface (Fig. 3.3.5).

EXAMPLE. A large closed tank is partly filled with 68°F (20°C) benzene. If the pressure on the surface is 10 lb/in^2, what is the pressure in the benzene at a depth of 11 ft below the liquid surface?

$$p_1 = \rho g h + p_2 = \frac{1.705 \times 32.17 \times 11}{144} + 10$$
$$= 14.19 \text{ lbf/in}^2 (9.784 \times 10^4 \text{ N/m}^2)$$

Ideal Gases (Compressible Fluids) For problems involving the upper atmosphere, it is necessary to take into account the variation of gravity with altitude. For this purpose, the **geopotential altitude** H is used, defined by $H = Z/(1 + z/r)$, where r is the radius of the earth

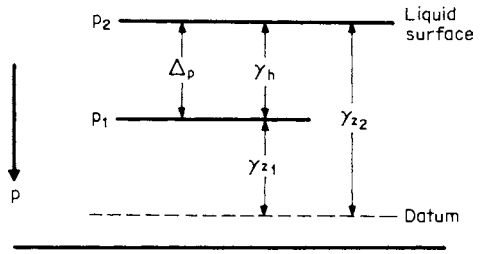

Fig. 3.3.5 Pressure equivalence.

($\approx 21 \times 10^6$ ft $\approx 6.4 \times 10^6$ m) and z is the height above sea level. The integration of the pressure-height equation depends upon the thermodynamic process. For an **isothermal process** $p_2/p_1 = e^{-(H_2-H_1)/RT}$ and for a **polytropic process** $(n \neq 1)$

$$\frac{p_2}{p_1} = \left[1 - \frac{(n-1)(H_2 - H_1)}{nRT_1}\right]^{n/(n-1)}$$

Temperature-height relations for a polytropic process $(n \neq 1)$ are given by

$$\frac{n}{1-n} = \frac{H_2 - H_1}{R(T_2 - T_1)}$$

Substituting in the **pressure-altitude** equation,

$$p_2/p_1 = (T_2/T_1)^{(H_2-H_1)\div R(T_1-T_2)}$$

EXAMPLE. The U.S. Standard Atmosphere 1962 (Sec. 11) is defined as having a sea-level temperature of 59°F (15°C) and a pressure of 2,116.22 lbf/ft^2. From sea level to a geopotential altitude of 36,089 ft (11,000 m) the temperature decreases linearly with altitude to −69.70°F (−56.5°C). Check the value of pressure ratio at this altitude given in the standard table.

Noting that $T_1 = 59 + 459.67 = 518.67$, $T_2 = -69.70 + 459.67 = 389.97$, and $R = 53.34$ ft · lbf/(lbm)(°R),

$$\begin{aligned} p_2/p_1 &= (T_2/T_1)^{(H_2-H_1)/R(T_1-T_2)} \\ &= (389.97/518.67)^{(36{,}089-0)/53.34(518.67-389.97)} \\ &= 0.2233 \text{ vs. tabulated value of } 0.2234 \end{aligned}$$

Pressure-Sensing Devices The two principal devices using liquids are the **barometer** and the **manometer.** The barometer senses absolute pressure and the manometer senses pressure differential. For discussion of the barometer and other pressure-sensing devices, refer to Sec. 16.

Manometers are a direct application of the basic equation of fluid statics and serve as a pressure standard in the range of 1/10 in of water to 100 lbf/in^2. The most familiar type of manometer is the **U tube** shown in Fig. 3.3.6*a*. Because of the necessity of observing both legs simultaneously, the **well** or **cistern** type (Fig. 3.3.6*b*) is sometimes used. The **inclined manometer** (Fig. 3.3.6*c*) is a special form of the well-type manometer designed to enhance the readability of small pressure differentials. Application of the basic equation of fluid statics to each of the types results in the following equations. For the **U tube,** $p_1 - p_2 = (\gamma_m - \gamma_f)h$, where γ_m and γ_f are the specific weights of the manometer and sensed fluids, respectively, and h is the vertical distance between the liquid interfaces. For the **well type,** $p_1 - p_2 = (\gamma_m - \gamma_f)(z_2) \times (1 + A_2/A_1)$, where A_1 and A_2 are as shown in Fig. 3.3.6*b* and z_2 is the vertical distance from the fill line to the upper interface. Commercial manufacturers of well-type manometers correct for the area ratios so that $p_1 - p_2 = (\gamma_m - \gamma_f)S$, where S is the scale reading and is equal to $z_1(1 + A_2/A_1)$. For this reason, scales should not be interchanged between U type or well type or between well types without consulting the manufacturer. For inclined manometers,

$$p_1 - p_2 = (\gamma_m - \gamma_f)(A_2/A_1 + \sin\theta)R$$

where R is the distance along the inclined tube. Commercial inclined manometers also have special scales so that $p_1 - p_2 = (\gamma_m - \gamma_f)S$, where $S = (A_2/A_1 + \sin\theta)R$.

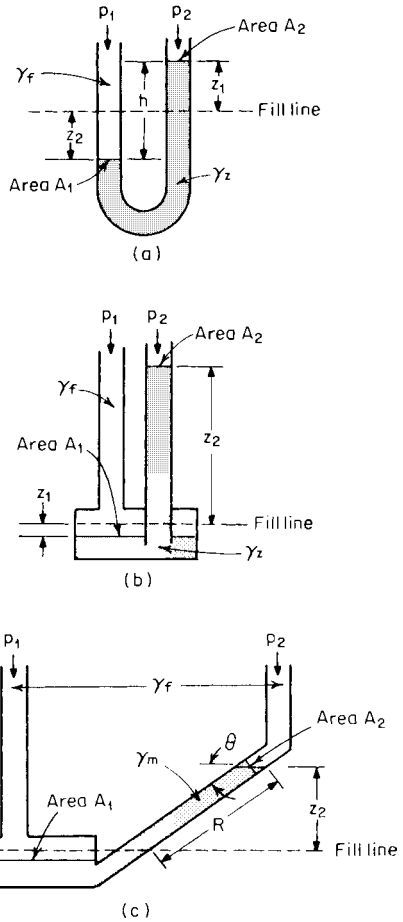

Fig. 3.3.6 (*a*) U-tube manometer; (*b*) well or cistern-type manometer; (*c*) inclined manometer.

EXAMPLE. A U-tube manometer containing mercury is used to sense the difference in water pressure. If the height between the interfaces is 10 in and the temperature is 68°F (20°C), what is the pressure differential?

$$\begin{aligned} p_1 - p_2 &= (\gamma_m - \gamma_f)h = g(\rho_m - \rho_f)h \\ &= 32.17(26.283 - 1.937)(10/12) \\ &= 652.7 \text{ lbf/ft}^2 (3.152 \times 10^4 \text{ N/m}^2) \end{aligned}$$

Liquid Forces The force exerted by a liquid on a **plane submerged surface** (Fig. 3.3.7) is given by $F = \int p\, dA = \gamma \int h \cdot dA = \gamma h, A$, where h_c is the distance from the liquid surface to the center of gravity of the surface, and A is the area of the surface. The location of the center of this force is given by

$$s_F = s_c + I_G/s_c A$$

where s_F is the inclined distance from the liquid surface to the center of force, s_c the inclined distance to the center of gravity of the surface, and I_G the moment of inertia around its center of gravity. Values of I_G are given in Sec. 5.2. See also Sec. 3.1. From Fig. 3.3.7, $h = R \sin\theta$, so that the vertical center of force becomes

$$h_F = h_c + I_G(\sin\theta)^2/h_c A$$

EXAMPLE. Determine the force and its location acting on a rectangular gate 3 ft wide and 5 ft high at the bottom of a tank containing 68°F (20°C) water, 12 ft deep, (1) if the gate is vertical, and (2) if it is inclined 30° from horizontal.

1. *Vertical gate*

$F = \gamma g h_c A = \rho g h_c A$
$= 1.937 \times 32.17(12 - 5/2)(5 \times 3)$
$= 8{,}800 \text{ lb}_f (3.914 \times 10^4 \text{ N})$
$h_F = h_c + I_G(\sin\theta)^2/h_c A$, from Sec. 5.2, I_G for a rectangle = (width)(height)^3/12
$h_F = (12 - 5/2) + (3 \times 5^3/12)(\sin 90°)^2/(12 - 5/2)(3 \times 5)$
$h_F = 9.719$ ft (2.962 m)

2. *Inclined gate*

$F = \gamma h_c A = \rho g h_c A$
$= 1.937 \times 32.17(12 - 5/2 \sin 30°)(5 \times 3)$
$= 10{,}048$ lbf $(4.470 \times 10^4$ N)
$h_F = h_c + I_G(\sin\theta)^2/h_c A$
$= (12 - 5/2 \sin 30°) + (3 \times 5^3/12)(\sin 30°)^2/(12 - 5/2 \sin 30°)(3 \times 5)$
$= 10.80$ ft (3.291 m)

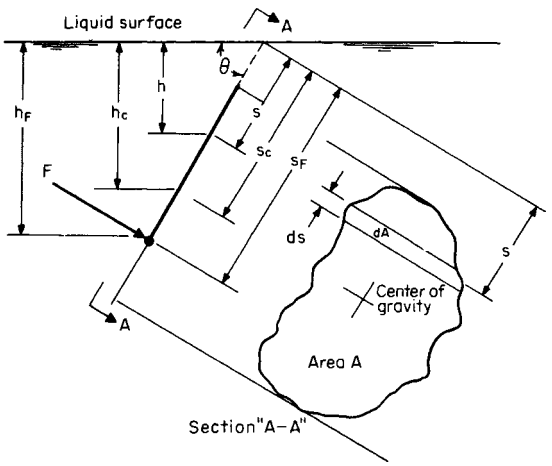

Fig. 3.3.7 Notation for liquid force on submerged surfaces.

Forces on irregular surfaces may be obtained by considering their horizontal and vertical components. The vertical component F_z equals the weight of liquid above the surface and acts through the centroid of the volume of the liquid above the surface. The horizontal component F_x equals the force on a vertical projection of the irregular surface. This force may be calculated by $F_x = \gamma h_{cx} A_x$, where h_{cx} is the distance from the surface center of gravity of the horizontal projection, and A_x is the projected area. The forces may be combined by $F = \sqrt{F_z^2 + F_z^2}$.

When fluid masses are **accelerated** without relative motion between fluid particles, the basic equation of fluid statics may be applied. For **translation** of a **liquid** mass due to uniform acceleration, the basic equation integrates to

$$p_2 - p_1 = -\rho[(x_2 - x_1)a_x + (y_2 - y_1)a_y + (z_2 - z_1)(a_z + g)]$$

EXAMPLE. An open tank partly filled with a liquid is being accelerated up an inclined plane as shown in Fig. 3.3.8. The uniform acceleration is 20 ft/s^2 and the angle of the incline is 30°. What is the angle of the free surface of the liquid? Noting that on the free surface $p_2 = p_1$ and that the acceleration in the y direction is zero, the basic equation reduces to

$$(x_2 - x_1)a_x + (z_2 - z_1)(a_z + g) = 0$$

Solving for tan θ,

$$\tan\theta = \frac{z_1 - z_2}{x_2 - x_1} = \frac{a_x}{a_z + g} = \frac{a\cos\alpha}{a\sin\alpha + g}$$
$$= (20\cos 30°)/(20\sin 30° + 32.17) = 0.4107$$
$$\theta = 22°20'$$

For **rotation** of liquid masses with uniform rotational acceleration, the basic equation integrates to

$$p_2 - p_1 = \rho\left[\frac{\omega^2}{2}(x_2^2 - x_1^2) - g(z_2 - z_1)\right]$$

where ω is the rotational speed in rad/s and x is the radial distance from the axis of rotation.

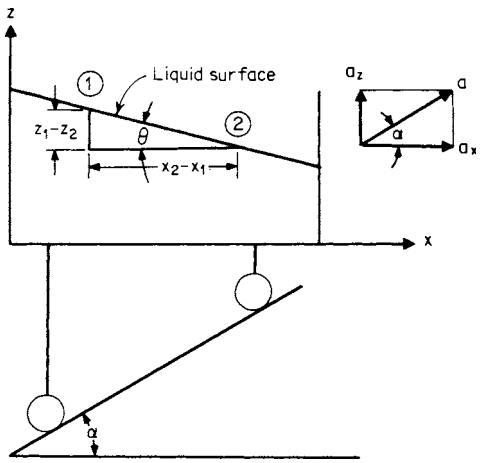

Fig. 3.3.8 Notation for translation example.

EXAMPLE. The closed cylindrical tank shown in Fig. 3.3.9 is 4 ft in diameter and 10 ft high and is filled with 104°F (40°C) benzene. The tank is rotated at 250 r/min about an axis 3 ft from its centerline. Compute the maximum pressure differential in the tank. Analysis of the rotation equation indicates that the maximum pressure will occur at the maximum rotational radius and the minimum elevation and, conversely, the minimum at the minimum rotational radius and maximum elevation. From Fig. 3.3.9, $x_1 = 3 - 4/2 = 1$ ft, $x_2 = 1 + 4 = 5$ ft, $z_2 - z_1 = -10$ ft, and the rotational speed $\omega = 2\pi N/60 = 2\pi(250)/60 = 26.18$ rad/s. Substituting

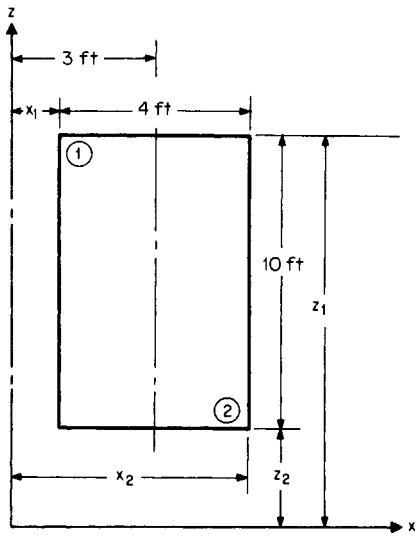

Fig. 3.3.9 Notation for rotation example.

into the rotational equation,

$$p_2 - p_1 = \rho\left[\frac{\omega^2}{2}(x_2^2 - x_1^2) - g(z_2 - z_1)\right]$$
$$= \frac{1.663}{144}\left[\frac{(26.18)^2}{2}(5^2 - 1^2) - 32.17(-10)\right]$$
$$= 98.70 \text{ lbf/in}^2 (6.805 \times 10^5 \text{ N/m}^2)$$

Buoyancy Archimedes' principle states that a body immersed in a fluid is buoyed up by a force equal to the weight of the fluid displaced. If an object immersed in a fluid is heavier than the fluid displaced, it will sink to the bottom, and if lighter, it will rise. From the free-body diagram of Fig. 3.3.10, it is seen that for vertical equilibrium,

$$\Sigma F_z = 0 = F_B - F_g - F_D$$

where F_B is the buoyant force, F_g the gravity force (weight of body), and F_D the force required to prevent the body from rising. The buoyant force

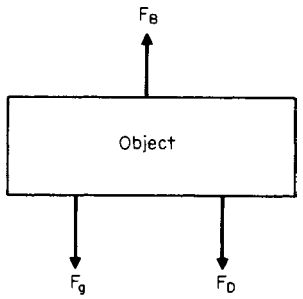

Fig. 3.3.10 Free body diagram of an immersed object.

being the weight of the displaced liquid, the equilibrium equation may be written as

$$F_D = F_B - F_g = \gamma_f V - \gamma_0 V = (\gamma_f - \gamma_0)V$$

where γ_f is the specific weight of the fluid, γ_0 is the specific weight of the object, and V is the volume of the object.

EXAMPLE. An airship has a volume of 3,700,000 ft^3 and is filled with hydrogen. What is its gross lift in air at 59°F (15°C) and 14.696 psia? Noting that $\gamma = p/RT$,

$$F_D = (\gamma_f - \gamma_0)V = \left(\frac{p}{R_a T} - \frac{p}{R_{H_2} T}\right)V$$
$$= \frac{pV}{T}\left(\frac{1}{R_a} - \frac{1}{R_{H_2}}\right)$$
$$= \frac{144 \times 14.696 \times 3{,}700{,}000}{59 + 459.7}\left(\frac{1}{53.34} - \frac{1}{766.8}\right)$$
$$= 263{,}300 \text{ lbf } (1.71 \times 10^6 \text{ N})$$

Flotation is a special case of buoyancy where $F_D = 0$, and hence $F_B = F_g$.

EXAMPLE. A crude **hydrometer** consists of a cylinder of ½ in diameter and 2 in length surmounted by a cylinder of ⅛ in diameter and 10 in long. Lead shot is added to the hydrometer until its total weight is 0.32 oz. To what depth would this hydrometer float in 104°F (40°C) glycerin? For flotation, $F_B = F_g = \gamma_f V = \rho_f g V$ or $V = F_B/\rho_f g = (0.32/16)/(2.423 \times 32.17) = 2.566 \times 10^{-4}$ ft^3. Volume of cylindrical portion of hydrometer $= V_c = \pi D^2 L/4 = \pi(0.5/12)^2(2/12)/4 = 2.273 \times 10^{-4}$ ft^3. Volume of stem immersed $= V_S = V - V_C = 2.566 \times 10^{-4} - 2.273 \times 10^{-4} = 2.930 = 10^{-5}$ ft^3. Length of immersed stem $= L_S = 4\,V_S/\pi D^2 = (4 \times 2.930 \times 10^{-5})/\pi(0.125/12)^2 = 0.3438$ ft $= 0.3438 \times 12 = 4.126$ in. Total immersion $= L + L_S = 2 + 4.126 = 6.126$ in (0.156 m).

Static Stability A body is in static equilibrium when the imposition of a small displacement brings into action forces that tend to restore the body to its original position. For **completely submerged bodies,** the center of buoyancy and the center of gravity must lie on the same vertical line and the center of buoyancy must be located above the center of gravity. Figure 3.3.11*a* shows a balloon and its basket in its normal position with the center of buoyancy *B* above and on the same vertical line as the center of gravity *G*. Figure 3.3.11*b* shows the balloon displaced from its normal position. In this position, there is a couple $F_g x$ which tends to restore the balloon and its basket to its original position. For **floating bodies,** the center of gravity and the center of buoyancy must lie on the

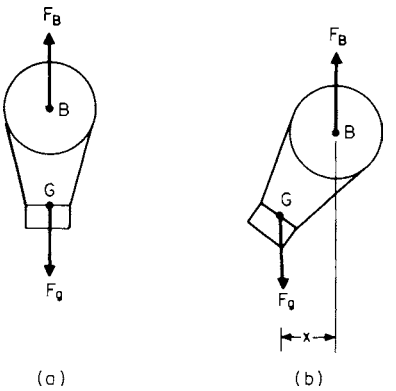

Fig. 3.3.11 Stability of an immersed body.

same vertical line, but the center of buoyancy may be below the center of gravity, as is common practice in surface-ship design. It is required that when displaced, the line of action of the buoyant force intersect the centerline above the center of gravity. Figure 3.3.12*a* shows a floating body in its normal position with its center of gravity *G* on the same vertical line and above the center of buoyancy *B*. Figure 3.3.12*b* shows the object displaced. The intersection of the line of action of the buoyant force with the centerline of the body at *M* is called the metacenter. As shown, this is above the center of buoyancy and sets up a restoring couple. When the metacenter is below the center of gravity, the object will capsize (see Sec. 11.3).

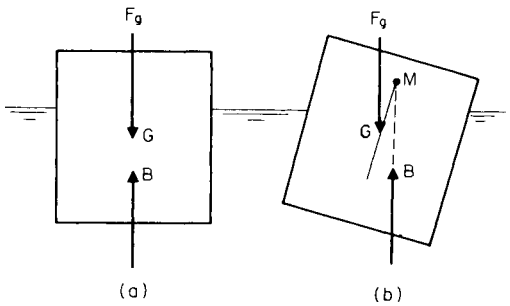

Fig. 3.3.12 Stability of a floating body.

FLUID KINEMATICS

Steady and Unsteady Flow If at every point in the fluid stream none of the local fluid properties changes with time, the flow is said to be steady. The mathematical conditions for steady flow are met when $\partial(\text{fluid properties})/\partial t = 0$. While flow is generally unsteady by nature, many real cases of unsteady flow may be treated as steady flow by using average properties or by changing the space reference. The amount of error produced by the averaging technique depends upon the nature of the unsteady flow, but the latter technique is error-free when it can be applied.

Streamlines and Stream Tubes Velocity has both magnitude and direction and hence is a vector. A **streamline** is a line which gives the *direction* of the velocity of a fluid particle at each point in the flow stream. When streamlines are connected by a closed curve in steady flow, they will form a boundary through which the fluid particles cannot

pass. The space between the streamlines becomes a **stream tube.** The stream-tube concept broadens the application of fluid-flow principles; for example, it allows treating the flow inside a pipe and the flow around an object with the same laws. A stream tube of decreasing size approaches its own axis, a central streamline; thus equations developed for a stream tube may also be applied to a streamline.

Velocity and Acceleration In the most general case of fluid motion, the resultant **velocity** U along a streamline is a function of both distance s and time t, or $U = f(s, t)$. In differential form,

$$dU = \frac{\partial U}{\partial s} ds + \frac{\partial U}{\partial t} dt$$

An expression for **acceleration** may be obtained by dividing the velocity equation by dt, resulting in

$$\frac{dU}{dt} = \frac{\partial U}{\partial s}\frac{ds}{dt} + \frac{\partial U}{\partial t}$$

for steady flow $\partial U/\partial t = 0$.

Velocity Profile In the flow of real fluids, the individual streamlines will have different velocities past a section. Figure 3.3.13 shows the steady flow of a fluid past a section (A-A) of a circular pipe. The **velocity profile** is obtained by plotting the velocity U of each streamline as it passes A-A. The stream tube that is formed by the space between the streamlines is the annulus whose area is dA, as shown in Fig. 3.3.13 for

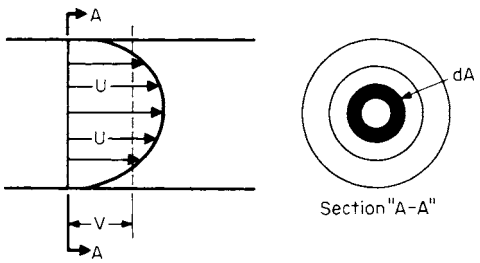

Fig. 3.3.13 Velocity profile.

the stream tube whose velocity is U. The volumetric rate of flow Q for the flow past section A-A is $Q = \int U\, dA$. All flows take place between boundaries that are **three-dimensional.** The terms **one-dimensional, two-dimensional,** and **three-dimensional** flow refer to the number of dimensions required to describe the velocity profile. For **three-dimensional** flow, a **volume** (L^3) is required; for example, the flow of a fluid in a circular pipe. For **two-dimensional** flow, an **area** (L^2) is necessary; for example, the flow between two parallel plates. For **one-dimensional** flow, a **line** (L) describes the profile. In cases of two- or three-dimensional flow, $\int U\, dA$ can be integrated either mathematically if the equations are known or graphically if velocity-measurement data are available. In many engineering applications, the **average velocity** V may be used where $V = Q/A = (1/A)\int U\, dA$.

The **continuity equation** is a special case of the general physical law of the conservation of mass. It may be simply stated for a control volume:

Mass rate entering = mass rate of storage + mass rate leaving

This may be expressed mathematically as

$$\rho U\, dA = \left[\frac{\partial}{\partial t}(\rho\, dA\, ds)\right] + \left[\rho U\, dA + \frac{\partial}{\partial s}(\rho U\, dA) ds\right]$$

where ds is an incremental distance along the control volume. For steady flow, $\partial/\partial t(\rho\, dA\, ds) = 0$, the general equation reduces to $d(\rho U\, dA) = 0$. Integrating the steady-flow **continuity equation** for the average velocity along a flow passage:

$$\rho VA = \text{a constant} = \rho_1 V_1 A_1 = \rho_2 V_2 A_2 = \cdots = \rho_n V_n A_n = \dot{M}$$

where $\dot{M}$ is the mass flow rate in slugs/s (14.5939 kg/s). In many engineering applications, the flow rate in pounds mass per second is desired, so that

$$\dot{m} = \frac{V_1 A_1}{v_1} = \frac{V_2 A_2}{v_2} = \cdots = \frac{V_n A_n}{v_n}$$

where $\dot{m}$ is the flow rate in lbm/s (0.4535924 kg/s).

EXAMPLE. Air discharges from a 12-in-diameter duct through a 4-in-diameter nozzle into the atmosphere. The pressure in the duct is 20 lbf/in^2, and atmospheric pressure is 14.7 lbf/in^2. The temperature of the air in the duct just upstream of the nozzle is 150°F, and the temperature in the jet is 147°F. If the velocity in the duct is 18 ft/s, compute (1) the mass flow rate in lbm/s and (2) the velocity in the nozzle jet. From the equation of state

$$\begin{aligned}
v &= RT/p \\
v_D &= RT_D/p_D = 53.34\ (150 + 459.7)/(144 \times 20) \\
&= 11.29\ \text{ft}^3/\text{lbm} \\
v_J &= RT_J/p_J = 53.34\ (147 + 459.7)/(144 \times 14.7) \\
&= 15.29\ \text{ft}^3/\text{lbm} \\
(1)\ \dot{m} &= V_D A_D/v_D = 18[(\pi/4)(12/12)^2]/11.29 \\
\dot{m}_J &= 1.252\ \text{lbm/s}\ (0.5680\ \text{kg/s}) \\
(2)\ VJ &= mv_J/A_J = (1.252)(15.29)/[(\pi/4)(4/12)^2] \\
v_J &= 219.2\ \text{ft/s}(66.82\ \text{m/s})
\end{aligned}$$

FLUID DYNAMICS

Equation of Motion For steady one-dimensional flow, consideration of forces acting on a fluid element of length dL, flow area dA, boundary perimeter in fluid contact dP, and change in elevation dz with a unit shear stress τ moving at a velocity of V results in

$$v\, dp + \frac{V\, dV}{g_c} + \frac{g}{g_c} dz + v\tau\left(\frac{dP}{dA}\right) dL = 0$$

Substituting $v = g/g_c\gamma$ and simplifying,

$$\frac{dp}{\gamma} + \frac{V\, dV}{g} + dz + dh_f = 0$$

where $dh_f = (\tau/\gamma)(dP/dA)\, dL = \tau\, dL/\gamma R_h$.

The expression $1/(dP/dA)$ is the **hydraulic radius** R_h and equals the flow area divided by the perimeter of the solid boundary in contact with the fluid. This perimeter is usually called the "wetted" perimeter. The hydraulic radius of a pipe flowing full is $(\pi D^2/4)/\pi D = D/4$. Values for other configurations are given in Table 3.3.6. Integration of the equation of motion for an incompressible fluid results in

$$\frac{p_1}{\gamma} + \frac{V_1^2}{2g} + z_1 = \frac{p_2}{\gamma} + \frac{V_2^2}{2g} + z_2 + h_{1f2}$$

Each term of the equation is in feet and is equivalent to the height the fluid would rise in a tube if its energy were converted into potential energy. For this reason, in hydraulic practice, each type of energy is referred to as a **head.** The **static pressure head** is p/γ. The **velocity head** is $V^2/2g$, and the **potential head** is z. The energy loss between sections h_{1f2} is called the **lost head** or **friction head.** The **energy grade line** at any point $\Sigma(p/\gamma + V^2/2g + z)$, and the **hydraulic grade line** is $\Sigma(p/\gamma + z)$ as shown in Fig. 3.3.14.

EXAMPLE. A 12-in pipe (11.938 in inside diameter) reduces to a 6-in pipe (6.065 in inside diameter). Benzene at 68°F (20°C) flows steadily through this system. At section 1, the 12-in pipe centerline is 10 ft above the datum, and at section 2, the 6-in pipe centerline is 15 ft above the datum. The pressure at section 1 is 20 lbf/in^2 and the velocity is 4 ft/s. If the head loss due to friction is $0.05\, V_2^2/2g$, compute the pressure at section 2. Assume $g = g_c$, $\gamma = \rho g = 1.705 \times 32.17 = 54.85$ lbf/ft^3. From the continuity equation,

$$\begin{aligned}
M &= \rho_1 A_1 V_1 = \rho_2 A_2 V_2 \qquad (p_1 = p_2) \\
V_2 &= V_1(A_1/A_2) = V_1(\pi D_1^2)/4)/(\pi D_2^2/4) = V_1(D_1/D_2)^2 \\
V_2 &= 4(11.938/6.065)^2 = 15.50\ \text{ft/s}
\end{aligned}$$

From the equation of motion,

$$\frac{p_2}{\gamma} = \frac{p_1}{\gamma} + \frac{V_1^2}{2g} + z_1 - \left(\frac{V_2^2}{2g} + z_2 + h_{1f2}\right)$$

$$\frac{p_2}{\gamma} = \frac{p_1}{\gamma} + \frac{V_1^2 - V_2^2 - 0.05V_2^2}{2g} + z_1 - z_2$$

Table 3.3.6 Values of Flow Area A and Hydraulic Radius R_h for Various Cross Sections

Cross section	Condition			Equations
	Flowing full	$h/D = 1$		$A = \pi D^2/4 \quad R_h = D/4$
	Upper half partly full	$0.5 < h/D < 1$		$\cos(\theta/2) = (2h/D - 1)$ $A = [\pi(360 - \theta) + 180 \sin\theta](D^2/1{,}440)$ $R_h = [1 + (180 \sin\theta)/(\pi\theta)](D/4)$
		$h/D = 0.8128$		$A = 0.6839\,D^2 \quad R_h \max = 0.3043D$
	Lower half partly full	$h/D = 0.5$		$A = \pi D^2/8 \quad R_h \max = h/2$
		$0 < h/D < 0.5$		$\cos(\theta/2) = (1 - 2h/D)$ $A = (\pi\theta - 180 \sin\theta)(D^2/1{,}440)$ $R_h = [1 - (180 \sin\theta)/(\pi\theta)](D/4)$
	Flowing full	$h/D = 1$		$A = bD \quad R_h = bD/2(b + D)$
		Square $b = D$		$A = D^2 \quad R_h = D/4$
	Partly full	$h/D < 1$ $h/b = 0.5$ $b \to \infty, h \to 0$		$A = bh \quad R_h = bh/(2h + b)$ $A = b^2/2 \quad R_h \max = h/2$ $R_h \to h$ (wide shallow stream)
	$\alpha \neq \beta$			$R_h \max = h/2$ $A = [b + 1/2h(\cot\alpha + \cot\beta)]h$ $R_h = A/[b + h(\csc\alpha + \csc\beta)]$
	$\alpha = \beta$	$\frac{h}{a} = \frac{1}{2}$	$\alpha = 26°34'$	$A = (b + 2h)h$ $R_h = (b + 2h)h/(b + 4.472h)$
		$\frac{h}{a} = \frac{\sqrt{3}}{3}$	$\alpha = 30°$	$A = (b + 1.732h)h$ $R_h = (b + 1.732h)h/(b + 4h)$
		$\frac{h}{a} = \frac{2}{3}$	$\alpha = 33°41'$	$A = (b + 1.5h)h$ $R_h = (b + 1.5h)h/(b + 3.606h)$
		$\frac{h}{a} = 1$	$\alpha = 45°$	$A = (b + h)h$ $R_h = (b + h)h/(b + 2.828h)$
		$\frac{h}{a} = \frac{3}{2}$	$\alpha = 56°19'$	$A = (b + 0.6667h)h$ $R_h = (b + 0.6667h)h/(b + 2.404h)$
		$\frac{h}{a} = \sqrt{3}$	$\alpha = 60°$	$A = (b + 0.5774h)h$ $R_h = (b + 0.5774h)h/(b + 2.309h)$
	θ = any angle			$A = \tan(\theta/2)h^2 \quad R_h = \sin(\theta/2)h/2$
	$\theta = 30$			$A = 0.2679h^2 \quad R_h = 0.1294h$
	$\theta = 45$			$A = 0.4142h^2 \quad R_h = 0.1913h$
	$\theta = 60$			$A = 0.5774h^2 \quad R_h = 0.2500h$
	$\theta = 90$			$A = h^2 \quad R_h = 0.3536h$

$$\frac{p_2}{\gamma} = \frac{144 \times 20}{54.85} + \frac{4^2 - 1.05(15.50)^2}{2 \times 32.17} + 10 - 15$$

$$\frac{p^2}{\gamma} = 43.83 \text{ ft}$$

$$p_2 = \frac{54.88 \times 43.83}{144} = 16.70 \text{ lbf/in}^2 \ (1.151 \times 10^5 \text{ N/m}^2)$$

Energy Equation Application of the principles of conservation of energy to a control volume for one-dimensional flow results in the following for steady flow:

$$J\,dq = dW + \frac{V\,dV}{g_c} + \frac{g}{g_c}dz + J\,du + d(pv)$$

where J is the mechanical equivalent of heat, 778.169 ft · lbf/Btu; q is the heat added, Btu/lbm (2,326 J/kg); W is the steady-flow shaft work done *by* the fluid; and u is the internal energy. Btu/lbm (2,326 J/kg). If the energy equation is integrated for an incompressible fluid,

$$J_1q_2 = {}_1W_2 + \frac{V_2^2 - V_1^2}{2g_c} + \frac{g}{g_c}(z_2 - z_1) + J(u_2 - u_1) + v(p_2 - p_1)$$

The equation of motion does not consider thermal energy or steady-flow work; the energy equation has no terms for friction. Subtracting the differential equation of motion from the energy equation and solving for friction results in

$$dh_f = (dW + J\,du + p\,dv - J\,dq)(g_c/g)$$

Integrating for an incompressible fluid ($dv = 0$),

$$h_{1f2} = [{}_1W_2 + J(u_2 - u_1) - J_1q_2](g_c/g)$$

In the absence of steady-flow work in the system, the effect of friction is to increase the internal energy and/or to transfer heat from the system.

For steady frictionless, incompressible flow, both the equation of motion and the energy equation reduce to

$$\frac{p_1}{\gamma} + \frac{V_1^2}{2g} + z_1 = \frac{p_2}{\gamma} + \frac{V_2^2}{2g} + z_2$$

which is known as the **Bernoulli equation.**

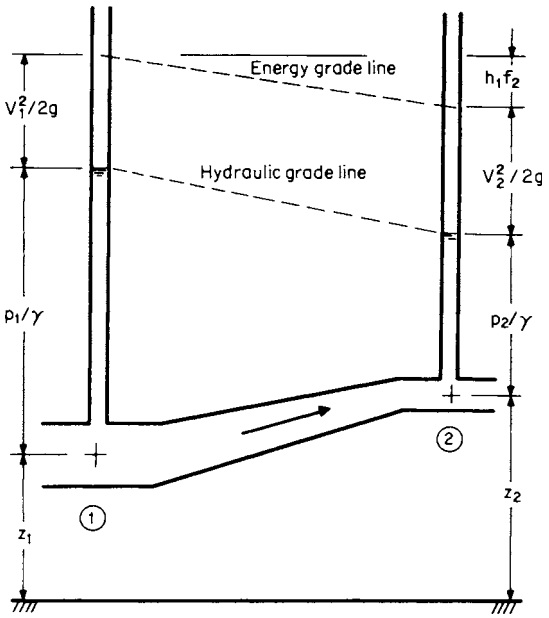

Fig. 3.3.14 Energy relations.

Area-Velocity Relations The continuity equation may be written as $\log_e \dot{M} = \log_e V + \log_e A + \log_e \rho$, which when differentiated becomes

$$\frac{dA}{A} = -\frac{dV}{V} - \frac{d\rho}{\rho}$$

For incompressible fluids, $d\rho = 0$, so

$$\frac{dA}{A} = -\frac{dV}{V}$$

Examination of this equation indicates

1. If the area increases, the velocity decreases.
2. If the area is constant, the velocity is constant.
3. There are no critical values.

For the frictionless flow of compressible fluids, it can be demonstrated that

$$\frac{dA}{A} = -\frac{dV}{V}\left[1 - \left(\frac{V}{c}\right)^2\right]$$

Analysis of the above equation indicates:

1. *Subsonic velocity* $V < c$. If the area increases, the velocity decreases. Same as for incompressible flow.
2. *Sonic velocity* $V = c$. Sonic velocity can exist only where the change in area is zero, i.e., at the *end* of a convergent passage or at the *exit* of a constant-area duct.
3. *Supersonic velocity* $V > c$. If area increases, the velocity increases, the reverse of incompressible flow. Also, supersonic velocity can exist only in the **expanding** portion of a passage **after** a constriction where **sonic** velocity existed.

Frictionless adiabatic compressible flow of an ideal gas in a horizontal passage must satisfy the following requirements:

1. *Conservation of mass.* As expressed by the continuity equation $M = \rho_1 A_1 V_1 = \rho_2 A_2 V_2$.
2. *Conservation of energy.* As expressed by the energy equation

$$\frac{V^2}{2g_c} + Ju + pv = \frac{V_1^2}{2g_c} + Ju_1 + p_1 v_1 = \frac{V_2^2}{2g_c} + Ju_2 + p_2 v_2$$

3. *Process relationship.* For an ideal gas undergoing a frictionless adiabatic (isentropic) process,

$$pv^k = p_1 v_1^k = p_2 v_2^k$$

4. *Ideal-gas law.* The equation of state for an ideal gas

$$pv = RT$$

In an expanding supersonic flow, a **compression shock wave** will be formed if the requirements for the conservation of mass and energy are not satisfied. This type of wave is associated with large and sudden rises in pressure, density, temperature, and entropy. The shock wave is so thin that for computation purposes it may be considered as a single line. For compressible flow of gases and vapors in passages, refer to Sec. 4.1; for steam-turbine passages, Sec. 9.4; for compressible flow around immersed objects, see Sec. 11.4.

The **impulse-momentum equation** is an application of the principle of conservation of momentum and is derived from Newton's second law. It is used to calculate the forces exerted on a solid boundary by a moving stream. Because velocity and force have both magnitude and direction, they are vectors. The impulse-momentum equation may be written for all three directions:

$$\Sigma F_x = \dot{M}(V_{x2} - V_{x1})$$
$$\Sigma F_y = \dot{M}(V_{y2} - V_{y1})$$
$$\Sigma F_z = \dot{M}(V_{z2} - V_{z1})$$

Figure 3.3.15 shows a free-body diagram of a control volume. The pressure forces shown are those imposed by the boundaries on the fluid and on the atmosphere. The reactive force R is that imposed by the downstream boundary on the fluid for equilibrium. Application of the impulse-momentum equation yields

$$\Sigma F = (F_{p1} + F_{a2}) - (F_{a1} + F_{p2} + R) = \dot{M}(V_2 - V_1)$$

Solving for R,

$$R = (p_1 - p_a)A_1 - (p_2 - p_a)A_2 = \dot{M}(V_2 = V_1)$$

The impulse-momentum equation is often used in conjunction with the continuity and energy equations to solve engineering problems. Because of the wide variety of possible applications, some examples are given to illustrate the methods of attack.

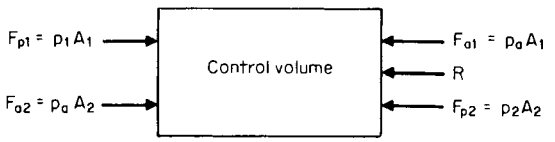

Fig. 3.3.15 Notation for impulse momentum.

EXAMPLE. **Compressible Fluid in a Duct.** Nitrogen flows steadily through a 6-in (5.761 in inside diameter) straight, horizontal pipe at a mass rate of 25 lbm/s. At section 1, the pressure is 120 lbf/in^2 and the temperature is 100°F. At section 2, the pressure is 80 lbf/in^2 and the temperature is 110°F. Find the friction force opposing the motion. From the equation of state,

$$v = RT/p$$
$$v_1 = 55.16(459.7 + 100)/(144 \times 120) = 1.787 \text{ ft}^3/\text{lbm}$$
$$v_2 = 55.16(459.7 + 110)/(144 \times 80) = 2.728 \text{ ft}^3/\text{lbm}$$

$$\text{Flow area of pipe} \times \pi D^2/4 = \pi(5.761/12)^2/4 = 0.1810 \text{ ft}^2$$

From the continuity equation,

$$v = \dot{m}V/A$$
$$V_1 = (25 \times 1.787)/0.1810 = 246.8 \text{ ft/s}$$
$$V_2 = (25 \times 2.728)/0.1810 = 376.8 \text{ ft/s}$$

Applying the free-body equation for impulse momentum ($A = A_1 = A_2$),

$$R = (p_1 - p_a)A_1 - (p_2 - p_a)A_2 - \dot{M}(V_2 - V_1)$$
$$= (p_1 - p_2)A - M(V_2 - V_1) = 144(120 - 80)\,0.1810$$
$$-(25/32.17)(376.8 - 246.8) = 941.5 \text{ lbf } (4.188 \times 10^3 \text{ N})$$

EXAMPLE. **Water Flow through a Nozzle.** Water at 68°F (20°C) flows through a horizontal 12- by 6-in-diameter nozzle discharging into the atmosphere. The pressure at the nozzle inlet is 65 lbf/in^2 and barometric pressure is 14.7 lbf/in^2. Determine the force exerted by the water on the nozzle.

$$A = \pi D^2/4$$
$$A_1 = \pi(12/12)^2/4 = 0.7854 \text{ ft}^2$$
$$A_2 = \pi(6/12)^2/4 = 0.1963 \text{ ft}^2$$
$$\gamma = \rho g = 1.937 \times 32.17 = 62.31 \text{ lb/ft}^3$$

From the continuity equation $\rho_1 A_1 V_1 = \rho_2 A_2 V_2$ for $\rho_1 = p_2$, $V_2 = V_1 A_1/A_2 = (0.7854/0.1963)V_1 = 4V_1$. From Bernoulli's equation ($z_1 = z_2$).

$$p_1/\gamma + V_1^2/2g = p_2/\gamma + V_2^2/2g = p_2/\gamma + (4V_1)^2/2g$$

or
$$V_1 = \sqrt{2g(p_1 - p_2)/15\gamma}$$
$$= \sqrt{2 \times 32.17 \times 144(65 - 14.7)/15 \times 62.31} = 22.33 \text{ ft/s}$$
$$V_2 = 4 \times 22.33 = 89.32 \text{ ft/s}$$

Again from the equation of continuity

$$\dot{M} = \rho_1 A_1 V_1 = 1.937 \times 0.7854 \times 22.33 = 33.97 \text{ slugs/s}$$

Applying the free-body equation for impulse momentum,

$$R = (p_1 - p_a)A_1 - (p_2 - p_a)A_2 - \dot{M}(V_2 - V_1)$$
$$= 144\,(65 - 14.7)0.7854 - 144\,(14.7 - 14.7)0.1963$$
$$= (33.97)\,(89.32 - 22.33)$$
$$= 3{,}413 \text{ lbf } (1.518 \times 10^4 \text{ N})$$

EXAMPLE. **Incompressible Flow through a Reducing Bend.** Carbon tetrachloride flows steadily without friction at 68°F (20°C) through a 90° horizontal reducing bend. The mass flow rate is 4 slugs/s, the inlet diameter is 6 in, and the outlet is 3 in. The inlet pressure is 50 lbf/in^2 and the barometric pressure is 14.7 lbf/in^2. Compute the magnitude and direction of the force required to "anchor" this bend.

$$A = \pi D^2/4$$
$$A_1 = (\pi/4)(6/12)^2 = 0.1963 \text{ ft}^2$$
$$A_2 = (\pi/4)(3/12)^2 = 0.04909 \text{ ft}^2$$

From continuity,

$$V = M/\rho A$$
$$V_1 = 4/(3.093)(0.1963) = 6.588 \text{ ft/s}$$
$$V_2 = 4/(3.093)(0.04909) = 26.35 \text{ ft/s}$$

From the Bernoulli equation ($z_1 = z_2$),

$$\frac{p_2}{\gamma} = \frac{p_1}{\gamma} + \frac{V_1^2}{2g} - \frac{V_2^2}{2g} = \frac{144 \times 50}{3.093 \times 32.17} + \frac{(6.588)^2 - (26.35)^2}{2 \times 32.17} = 62.24 \text{ ft}$$
$$p_2 = \frac{(3.093 \times 32.17)(62.24)}{144} = 43.01 \text{ lbf/in}^2$$

From Fig. 3.3.16,

$$\Sigma F_x = (p_1 - p_a)A_1 - (p_2 - p_a)A_2 \cos\alpha - R_x$$
$$= M(V_2 \cos\alpha - V_1)$$

or
$$R_x = (p_1 - p_a)A_1 - (p_2 - p_a)A_2 \cos\alpha - \dot{M}(V_2 \cos\alpha - V_1)$$
$$\Sigma F_y = 0 - (p_2 - p_a)A_2 \sin\alpha + R_y = \dot{M}(V_2 \sin\alpha - 0)$$

or
$$R_y = (p_2 - p_a)A_2 \sin\alpha + MV_2 \sin\alpha$$
$$R_x = 144\,(50 - 14.7)0.1963 - 144\,(43.01 - 14.7)(\cos 90°)$$
$$- 4\,(26.35 \cos 90° - 6.588)$$
$$= 1{,}024 \text{ lbf}$$
$$R_y = 144\,(43.01 - 14.7)(0.04909) \sin 90° + 4(26.35)(\sin 90°)$$
$$= 305.5 \text{ lbf}$$
$$R = \sqrt{R_x^2 + R_y^2} = \sqrt{(1{,}024)^2 + (305.5)^2}$$
$$= 1{,}068 \text{ lbf}_f (4.753 \times 10^3 \text{ N})$$
$$\theta = \tan^{-1}(F_y/F_x) = \tan^{-1}(305.5/1{,}024)$$
$$= 16°37'$$

Forces on Blades and Deflectors The forces imposed on a fluid jet whose velocity is V_J by a blade moving at a speed of V_b away from the jet are shown in Fig. 3.3.17. The following equations were developed from the application of the impulse-momentum equation for an open jet ($p_2 = p_1$) and for **frictionless** flow:

$$F_x = \rho A_J (V_J - V_b)^2 (1 - \cos\alpha)$$
$$F_y = \rho A_J (V_J - V_b)^2 \sin\alpha$$
$$F = 2\rho A_J (V_J - V_b)^2 \sin(\alpha/2)$$

EXAMPLE. In the nozzle-blade system of Fig. 3.3.17, water at 68°F (20°C) enters a 3- by 1½-in-diameter horizontal nozzle with a pressure of 23 lbf/in^2 and discharges at 14.7 lbf/in^2 (atmospheric pressure). The blade moves away from the nozzle at a velocity of 10 ft/s and deflects the stream through an angle of 80°. For

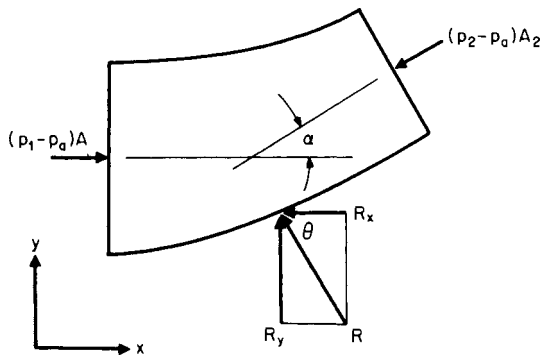

Fig. 3.3.16 Forces on a bend.

frictionless flow, calculate the total force exerted by the jet on the blade. Assume $g = g_c$; then $\gamma = \rho g$. From the continuity equation ($\rho_I = \rho_J$), $\rho_I A_I V_I = \rho_J A_J V_J$, $V_I = (A_J/A_I)V_J$,

$$V_J = \frac{\pi D_J^2/4}{\pi D_I^2/4} V_J = \left(\frac{D_J}{D_I}\right)^2 V_J$$
$$V_I = (1.5/3)^2 V_J = V_J/4$$

From the Bernoulli equation ($z_2 = z_1$),

$$\frac{V_J^2}{2g} = \frac{V_I^2}{2g} + \frac{p_I - p_J}{\rho g}$$
$$\frac{V_J^2 - (V_J/4)^2}{2g} = \frac{(p_I - p_J)}{\rho g}$$
$$V_J = \sqrt{\frac{2(16/15)(p_I - p_J)}{\rho}}$$
$$= \sqrt{\frac{2 \times (16/15)\,144\,(23 - 14.7)}{1.937}} = 36.28 \text{ ft/s}$$

The total force $F = 2\rho A_J (V_J - V_b)^2 \sin(\alpha/2)$

$$F = 2 \times 1.937(\pi/4)(1.5/12)^2(36.28 - 10)^2 \sin(80/2)$$
$$= 21.11 \text{ lbf } (93.90 \text{ N})$$

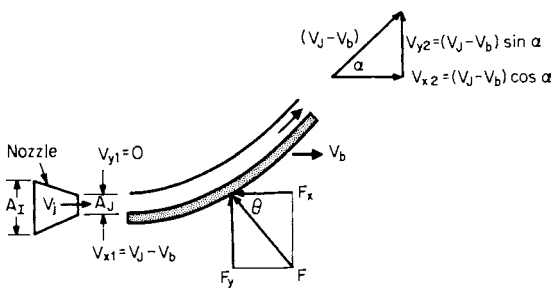

Fig. 3.3.17 Notation for blade study.

Impulse Turbine In a turbine, the total of the separate forces acting simultaneously on each blade equals that caused by the combined mass flow rate $\dot{M}$ discharged by the nozzle or

$$\Sigma P = \Sigma F_x V_b = \dot{M}(V_J - V_b)(1 - \cos\alpha)V_b$$

The maximum value of power P is found by differentiating P with respect to V_b and setting the result equal to zero. Solving for V_b yields $V_b = V_J/2$, so that maximum power occurs when the velocity of the jet is equal to twice the velocity of the blade. Examination of the power equation also indicates that the angle α for a maximum power results

when $\cos\theta = -1$ or $\alpha = 180°$. For theoretical maximum power of a blade, $2V_b = V_J$ and $\alpha = 180°$. It should be noted that in any practical impulse-turbine application, α cannot be 180° because the discharge interferes with the next set of blades. Substituting $V_b = V_J/2$, $\alpha = 180°$ in the power equation,

$$\Sigma P_{\max} = \dot{M}(V_J - V_J/2)[1 - (-1)]V_J/2 = MV_J^2/2 = \dot{m}V_J^2/2g_c$$

or the maximum power per unit mass is equal to the total power of the jet. Application of the Bernoulli equation between the surface of a reservoir and the discharge of the turbine shows that $\Sigma P_{\max} = \dot{M}\sqrt{2g(z_2 - z_1)}$. For design details, see Sec. 9.9.

Flow in a Curved Path When a fluid flows through a bend, it is also rotated around an axis and the energy required to produce rotation must be supplied from the energy already in the fluid mass. This fluid rotation is called a **free vortex** because it is free of outside energy. Consider the fluid mass $\rho(r_o - r_i)\,dA$ of Fig. 3.3.18 being rotated as it flows through a bend of outer radius r_o, inner radius r_i, with a velocity of V. Application of Newton's second law to this mass results in

$$dF = p_o\,dA - p_i\,dA = [\rho(r_o - r_i)\,dA][V^2/(r_o + r_i)/2]$$

which reduces to

$$p_o - p_i = 2(r_o - r_i)\rho V^2/(r_o + r_i)$$

Because of the difference in fluid pressure between the inner and outer walls of the bend, secondary flows are set up, and this is the primary cause of friction loss of bends. These secondary flows set up turbulence that require 50 or more straight pipe diameters downstream to dissipate.

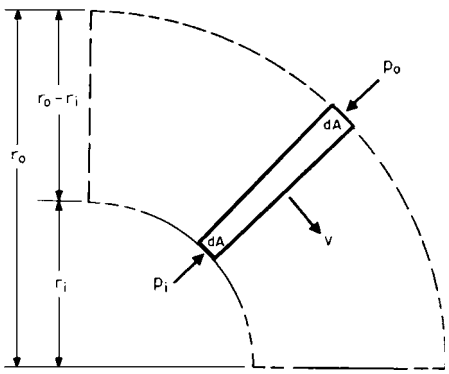

Fig. 3.3.18 Notation for flow in a curved path.

Thus this loss does not take place in the bend, but in the downstream system. These losses may be reduced by the use of splitter plates which help minimize the secondary flows by reducing $r_o - r_i$ and hence $p_o - p_i$.

EXAMPLE. 104°F (40°C) benzene flows at a rate of 8 ft³/s in a square horizontal duct. This duct makes a 90° turn with an inner radius of 1 ft and an outer radius of 2 ft. Calculate the difference between the walls of this bend. The area of this duct is $(r_o - r_i)^2 = (2 - 1)^2 = 1$ ft². From the continuity equation $V = Q/A = 8/1 = 8$ ft/s. The pressure difference

$$\begin{aligned} p_o - p_i &= 2(r_o - r_i)\rho V^2/(r_o + r_i) \\ &= 2(2 - 1)1.663\,(8)^2/(2 + 1) = 70.95\ \text{lbf/ft}^2 \\ &= 70.95/144 = 0.4927\ \text{lbf/in}^2\ (3.397 \times 10^3\ \text{N/m}^2) \end{aligned}$$

DIMENSIONLESS PARAMETERS

Modern engineering practice is based on a combination of theoretical analysis and experimental data. Often the engineer is faced with the necessity of obtaining practical results in situations where for various reasons, physical phenomena cannot be described mathematically and experimental data must be considered. The generation and use of **dimensionless parameters** provides a powerful and useful tool in (1) reducing the number of variables required for an experimental program, (2) establishing the principles of model design and testing, (3) developing equations, and (4) converting data from one system of units to another. Dimensionless parameters may be generated from (1) **physical equations,** (2) the principles of **similarity,** and (3) **dimensional analysis.** All **physical equations** must be dimensionally correct so that a dimensionless parameter may be generated by simply dividing one side of the equation by the other. A minimum of two dimensionless parameters will be formed, one being the inverse of the other.

EXAMPLE. It is desired to generate a series of dimensionless parameters to describe the ratios of static pressure head, velocity head, and potential head to total head for frictionless incompressible flow. From the Bernoulli equation,

$$\frac{p}{\gamma} + \frac{V^2}{2g} + z = \Sigma h = \text{total head}$$

$$N_1 = \frac{p/\gamma + V^2/2g + z}{\Sigma h} = \frac{p/\gamma}{\Sigma h} + \frac{V^2/2g}{\Sigma h} + \frac{z}{\Sigma h} = N_p + N_V + N_z$$

or

$$N_2 = \frac{\Sigma h}{p_2/\gamma + V^2/2g + z} = N_1^{-1}$$

N_1 and N_2 are total energy ratios and N_p, N_V, and N_z are the ratios of the static pressure head, velocity head, and potential head, respectively, to the total head.

Models versus Prototypes There are times when for economic or other reasons it is desirable to determine the performance of a structure or machine by testing another structure or machine. This type of testing is called model testing. The equipment being tested is called a **model,** and the equipment whose performance is to be predicted is called a **prototype.** A **model** may be smaller than, the same size as, or larger than the **prototype.** Model experiments on aircraft, rockets, missiles, pipes, ships, canals, turbines, pumps, and other structures and machines have resulted in savings that more than justified the expenditure of funds for the design, construction, and testing of the model. In some situations, the model and the prototype may be the same piece of equipment, for example, the laboratory calibration of a flowmeter with water to predict its performance with other fluids. Many manufacturers of fluid machinery have test facilities that are limited to one or two fluids and are forced to test with what they have available in order to predict performance with nonavailable fluids. For towing-tank testing of ship models and for wind-tunnel testing of aircraft and aircraft-component models, see Secs. 11.4 and 11.5.

Similarity Requirements For complete similarity between a model and its prototype, it is necessary to have **geometric, kinematic,** and **dynamic** similarity. **Geometric similarity** exists between model and prototype when the **ratios** of all corresponding dimensions of the model and prototype are equal. These ratios may be written as follows:

Length:
$$\begin{aligned} L_{\text{model}}/L_{\text{prototype}} &= L_{\text{ratio}} \\ &= L_m/L_p = L_r \end{aligned}$$

Area:
$$\begin{aligned} L^2_{\text{model}}/L^2_{\text{prototype}} &= L^2_{\text{ratio}} \\ &= L_m^2/L_p^2 = L_r^2 \end{aligned}$$

Volume:
$$\begin{aligned} L^3_{\text{model}}/L^3_{\text{prototype}} &= L^3_{\text{ratio}} \\ &= L_m^3/L_p^3 = L_r^3 \end{aligned}$$

Kinematic similarity exists between model and prototype when their streamlines are geometrically similar. The kinematic ratios resulting from this condition are

Acceleration:
$$\begin{aligned} a_r &= a_m/a_p = L_m T_m^{-2}/L_p T_p^{-2} \\ &= L_r/T_r^{-2} \end{aligned}$$

Velocity:
$$\begin{aligned} V_r &= V_m/V_p = L_m T_m^{-1}/L_p T_p^{-1} \\ &= L_r/T_r^{-1} \end{aligned}$$

Volume flow rate:
$$\begin{aligned} Q_r &= Q_m/Q_p = L_m^3 T_m^{-1}/L_p^3 T_p^{-1} \\ &= L_r^3/T_r^{-1} \end{aligned}$$

Dynamic similarity exists between model and prototype having geometric and kinematic similarity when the ratios of all forces are the same. Consider the model/prototype relations for the flow around the object shown in Fig. 3.3.19. For **geometric similarity** $D_m/D_p = L_m/L_p = L_r$ and for **kinematic similarity** $U_{Am}/U_{Ap} = U_{Bm}/U_{Bp} = V_r = L_r T_r^{-1}$.

Next consider the three forces acting on point C of Fig. 3.3.19 without specifying their nature. From the geometric similarity of their vector polygons and Newton's law, for **dynamic similarity** $F_{1m}/F_{1p} = F_{2m}/F_{2p} = F_{3m}/F_{3p} = M_m a_{Cm}/M_p a_{Cp} = F_r$. For dynamic similarity, these force ratios must be maintained on all corresponding fluid particles

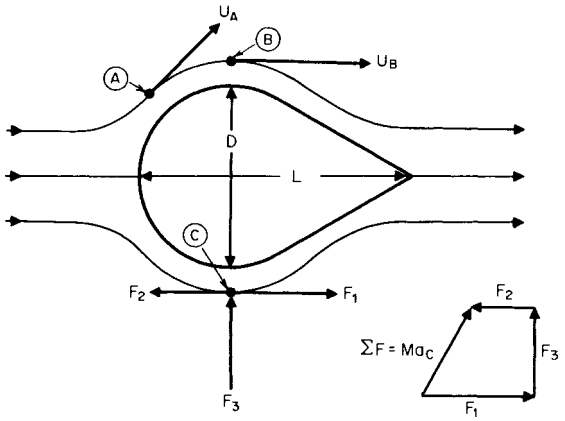

Fig. 3.3.19 Notation for dynamic similarity.

throughout the flow pattern. From the force polygon of Fig. 3.3.19, it is evident that $F_1 + \rightarrow F_2 + \rightarrow F_3 = Ma_C$. For total model/prototype force ratio, comparisons of force polygons yield

$$F_r = \frac{F_{1m} + \rightarrow F_{2m} + \rightarrow F_{3m}}{F_{1p} + \rightarrow F_{2p} + \rightarrow F_{3p}} = \frac{M_m a_{Cm}}{M_p a_{Cp}}$$

Fluid Forces The fluid forces that are considered here are those acting on a fluid element whose mass $= \rho L^3$, area $= L^2$, length $= L$, and velocity $= L/T$.

Inertia force F_i = (mass)(acceleration)
$= (\rho L^3)(L/T^2) = \rho L(L^2/T^2)$
$= \rho L^2 V^2$

Viscous force F_μ = (viscous shear stress)(shear area)
$= \tau L^2 = \mu(dU/dy)L^2 = \mu(V/L)L^2$
$= \mu LV$

Gravity force F_g = (mass)(acceleration due to gravity)
$= (\rho L^3)(g) = \rho L^3 g$

Pressure force F_p = (pressure)(area) $= pL^2$

Centrifugal force F_ω = (mass)(acceleration)
$= (\rho L^3)(L/T^2)$
$= (\rho L^3)(L\omega^2) = \rho L^4 \omega^2$

Elastic force F_E = (modulus of elasticity)(area)
$= EL^2$

Surface-tension force F_σ = (surface tension)(length) $= \sigma L$

Vibratory force F_f = (mass)(acceleration)
$= (\rho L^3)(L/T^2)$
$= (\rho L^4)(T^{-2}) = \rho L^4 f^2$

If all fluid forces were acting on a fluid element,

$$F_r = \frac{F_{\mu m} + \rightarrow F_{gm} + \rightarrow F_{pm} + \rightarrow F_{\omega m} + \rightarrow F_{Em} + \rightarrow F_{\sigma m} + \rightarrow F_{fm}}{F_{\mu p} + \rightarrow F_{gp} + \rightarrow F_{pp} + \rightarrow F_{\omega p} + \rightarrow F_{Ep} + \rightarrow F_{\sigma p} + \rightarrow F_{fp}} = \frac{F_{im}}{F_{ip}}$$

Examination of the above equation and the force polygon of Fig. 3.3.19 lead to the conclusion that dynamic similarity can be characterized by an equality of force ratios one less than the total number involved. Any force ratio may be eliminated, depending upon the quantities which are desired. Fortunately, in most practical engineering problems, not all of the eight forces are involved because some may not be acting, may be of negligible magnitude, or may be in opposition to each other in such a way as to compensate. In each application of similarity, a good understanding of the fluid phenomena involved is necessary to eliminate the irrelevant, trivial, or compensating forces. When the flow phenomenon is too complex to be readily analyzed, or is not known, only experimental verification with the prototype of results from a model test will determine what forces should be considered in future model testing.

Standard Numbers With eight fluid forces that can act in flow situations, the number of dimensionless parameters that can be formed from

Table 3.3.7 Standard Numbers

Force ratio	Equations	Result	Conventional practice: Form	Symbol	Name
Inertia / Viscous	$\frac{F_i}{F_u} = \frac{\rho L^2 V^2}{\mu LV}$	$\frac{\rho LV}{\mu}$	$\frac{\rho LV}{\mu}$	**R**	Reynolds
Inertia / Gravity	$\frac{F_i}{F_g} = \frac{\rho L^2 V^2}{\rho L^3 g}$	$\frac{V^2}{Lg}$	$\frac{V}{\sqrt{Lg}}$	**F**	Froude
Inertia / Pressure	$\frac{F_i}{F_p} = \frac{\rho L^2 V^2}{\rho L^2}$	$\frac{\rho V^2}{p}$	$\frac{\rho V^2}{p}$	**E**	Euler
			$\frac{2\Delta p}{\rho V^2}$	**Cp**	Pressure coefficient
Inertia / Centrifugal	$\frac{F_i}{F_\omega} = \frac{\rho L^2 V^2}{\rho L^4 \omega^2}$	$\frac{V^2}{L^2\omega^2}$	$\frac{V}{DN}$	**V**	Velocity ratio
Inertia / Elastic	$\frac{F_i}{F_E} = \frac{\rho L^2 V^2}{EL^2}$	$\frac{\rho V^2}{E}$	$\frac{\rho V^2}{E}$	**C**	Cauchy
			$\frac{V}{\sqrt{E/\rho}}$	**M**	Mach
Inertia / Surface tension	$\frac{F_i}{F_\sigma} = \frac{\rho L^2 V^2}{\sigma^L}$	$\frac{\rho LV^2}{\sigma}$	$\frac{\rho LV^2}{\sigma}$	**W**	Weber
Inertia / Vibration	$\frac{F_i}{F_f} = \frac{\rho L^2 V^2}{\rho L^4 f^2}$	$\frac{V^2}{L^2 f^2}$	$\frac{Lf}{V}$	**S**	Strouhal

SOURCE: Computed from data given in Murdock, "Fluid Mechanics and Its Applications," Houghton Mifflin, 1976.

their ratios is 56. However, conventional practice is to ratio the inertia force to the other fluid forces, usually by division because the inertia force is the vector sum of all the other forces involved in a given flow situation. Results obtained by dividing the inertia force by each of the other forces are shown in Table 3.3.7 compared with the standard numbers that are used in conventional practice.

DYNAMIC SIMILARITY

Vibration In the flow of fluids around objects and in the motion of bodies immersed in fluids, **vibration** may occur because of the formation of a wake caused by alternate shedding of eddies in a periodic fashion or by the vibration of the object or the body. The **Strouhal number S** is the ratio of the velocity of vibration Lf to the velocity of the fluid V. Since the vibration may be fluid-induced or structure-induced, two frequencies must be considered, the wake frequency $f\omega$ and the natural frequency of the structure f_n. Fluid-induced forces are usually of small magnitude, but as the wake frequency approaches the natural frequency of the structure, the vibratory forces increase very rapidly. When $f\omega = f_n$, the structure will go into resonance and fail. This imposes on the model designer the requirement of matching to scale the natural-frequency characteristics of the prototype. This subject is treated later under Wake Frequency. All further discussions of model/prototype relations are made under the assumption that either vibratory forces are absent or they are taken care of in the design of the model or in the test program.

Incompressible Flow Considered in this category are the flow of fluids around an object, motion of bodies immersed in incompressible fluids, and the flow of incompressible fluids in conduits. It includes, for example, a submarine traveling under water but not partly submerged, and liquids flowing in pipes and passages when the liquid completely fills them, but not when partly full as in open-channel flow. It also includes aircraft moving in atmospheres that may be considered incompressible. Incompressible flow in rotating machinery is considered separately.

In these situations the gravity force, although acting on all fluid particles, does not affect the flow pattern. Excluding rotating machinery, centrifugal forces are absent. By definition of an incompressible fluid, elastic forces are zero, and since there is no liquid-gas interface, surface-tension forces are absent.

The only forces now remaining for consideration are the inertia, viscous, and pressure. Using standard numbers, the parameters are **Reynolds number** and **pressure coefficient.** The Reynolds number may be converted into a kinematic ratio by noting that by definition $\nu = \mu/\rho$ and substituting in $\mathbf{R} = \rho LV/\mu = LV/\nu$. In this form, Reynolds number is the ratio of the fluid velocity V and the "shear velocity" ν/L. For this reason, Reynolds number is used to characterize the velocity profile. Forces and pressure losses are then determined by the pressure coefficient.

EXAMPLE. A submarine is to move submerged through 32°F (0°C) seawater at a speed of 10 knots. (1) At what speed should a 1:20 model be towed in 68°F (20°C) fresh water? (2) If the thrust on the model is found to be 42,500 lbf, what horsepower will be required to propel the submarine?

1. Speed of model for Reynolds-number similarity

$$R_m = R_p = \left(\frac{\rho VL}{\mu}\right)_m = \left(\frac{\rho VL}{\mu}\right)_p$$
$$V_m = V_p(\rho_p/\rho_m)(L_p/L_m)(\mu_m/\mu_p)$$
$$V_m = (10)(1.995/1.937)(20/1)(20.92 \times 10^{-6}/39.40 \times 10^{-6})$$
$$= 109.4 \text{ knots } (56.27 \text{ m/s})$$

2. Prototype horsepower

$$\mathbf{C}_{pp} = \mathbf{C}_{pm} = \left(\frac{2\Delta p}{\rho V^2}\right)_p = \left(\frac{2\Delta p}{\rho V^2}\right)_m$$
$$F = \Delta p L^2,\ \Delta p = \frac{F}{L^2},\ \text{so that } \left(\frac{2F}{\rho V^2 L^2}\right)_p = \left(\frac{2F}{\rho V^2 L^2}\right)_m$$
$$F_p = F_m(\rho_p/\rho_m)(V_p/V_m)^2(L_p/L_m)^2$$
$$= 42{,}500(1.995/1.937)(10/109.4)^2(20/1)^2 = 146{,}300 \text{ lbf}$$
$$P = FV = \left(\frac{146{,}300}{550}\right)\left(\frac{10 \times 6{,}076}{3{,}600}\right)$$
$$= 4{,}490 \text{ hp } (3.35 \times 10^6 \text{ W})$$

Compressible Flow Considered in this category are the flow of compressible fluids under the conditions specified for incompressible flow in the preceding paragraphs. In addition to the forces involved in incompressible flow, the elastic force must be added. Conventional practice is to use the square root of the inertia/elastic force ratio or **Mach number.**

Mach number is the ratio of the fluid velocity to its speed of sound and may be written $\mathbf{M} = V/c = V\sqrt{E_s/\rho}$. For an ideal gas, $\mathbf{M} = V/\sqrt{kg_cRT}$. In compressible-flow problems, practice is to use the Mach number to characterize the velocity or kinematic similarity, the Reynolds number for dynamic similarity, and the pressure coefficient for force or pressure-loss determination.

EXAMPLE. An airplane is to fly at 500 mi/h in an atmosphere whose temperature is 32°F (0°C) and pressure is 12 lbf/in^2. A 1:20 model is tested in a wind tunnel where a supply of air at 392°F (200°C) and variable pressure is available. At (1) what speed and (2) what pressure should the model be tested for dynamic similarity?

1. *Speed for Mach-number similarity*

$$\mathbf{M}_m = \mathbf{M}_p = \left(\frac{V}{\sqrt{E/\rho}}\right)_m = \left(\frac{V}{\sqrt{E/\rho}}\right)_p = \left(\frac{V}{\sqrt{kg_cRT}}\right)_m = \left(\frac{V}{\sqrt{kg_cRT}}\right)_p$$
$$V_m = V_p(k_m/k_p)^{1/2}(R_m/R_p)^{1/2}(T_m/T_p)^{1/2}$$

For the same gas $k_m = k_p$, $R_m = R_p$, and

$$V_m = V_p\sqrt{T_m/T_p} = 500\sqrt{(851.7/491.7)} = 658.1 \text{ mi/h}$$

2. *Pressure for Reynolds-number similarity*

$$\mathbf{R}_m = \mathbf{R}_p = \left(\frac{\rho VL}{\mu}\right)_m = \left(\frac{\rho VL}{\mu}\right)_p$$
$$\rho_m = \rho_p(V_p/V_m)(L_p/L_m)(\mu_m/\mu_p)$$

Since $\rho = p/g_cRT$

$$\left(\frac{p}{g_cRT}\right)_m = \left(\frac{p}{g_cRT}\right)_p\left(\frac{V_p}{V_m}\right)\left(\frac{L_p}{L_m}\right)\left(\frac{\mu_m}{\mu_p}\right)$$
$$p_m = p_p(T_m/T_p)(V_p/V_m)(L_p/L_m)(\mu_m/\mu_p)$$
$$p_m = 12(851.7/491.7)(500/658.1)(20/1)(53.15 \times 10^{-6}/35.67 \times 10^{-6})$$
$$p_m = 470.6 \text{ lbf/in}^2 \ (3.245 \times 10^6 \text{ N/m}^2)$$

For information about wind-tunnel testing and its limitations, refer to Sec. 11.4.

Centrifugal Machinery This category includes the flow of fluids in such centrifugal machinery as compressors, fans, and pumps. In addition to the inertia, pressure, viscous, and elastic forces, centrifugal forces must now be considered. Since centrifugal force is really a special case of the inertia force, their ratio as shown in Table 3.3.7 is **velocity ratio** and is the ratio of the fluid velocity to the machine tangential velocity. In model/prototype relations for centrifugal machinery, DN (D = diameter, ft, N = rotational speed) is substituted for the velocity V, and D for L, which results in the following:

$$\mathbf{M} = DN/\sqrt{kg_cRT} \qquad \mathbf{R} = \rho D^2N/\mu \qquad \mathbf{C}_p = 2\Delta p/\rho D^2N^2$$

EXAMPLE. A centrifugal compressor operating at 100 r/min is to compress methane delivered to it at 50 lbf/in^2 and 68°F (20°C). It is proposed to test this compressor with air from a source at 140°F (60°C) and 100 lbf/in^2. Determine compressor speed and inlet-air pressure required for dynamic similarity.
Find speed for Mach-number similarity:

$$\mathbf{M}_m = \mathbf{M}_p = (DN/\sqrt{kg_cRT})_m = (DN/\sqrt{kg_cRT})_p$$
$$N_m = N_p(D_p/D_m)\sqrt{(k_m/k_p)(R_m/R_p)(T_m/T_p)}$$
$$= 100(1)\sqrt{(1.40/1.32)(53.34/96.33)(599.7/527.7)}$$
$$= 81.70 \text{ r/min}$$

Find pressure for Reynolds-number similarity:

$$\mathbf{R}_m = \mathbf{R}_p = \left(\frac{\rho D^2N}{\mu}\right)_m = \left(\frac{\rho D^2N}{\mu}\right)_p$$

For an ideal gas $\rho = p/g_c RT$, so that

$$(pD^2N/g_cRT\mu)_m = (pD^2N/g_cRT\mu)_p$$
$$p_m = p_p(D_p/D_m)^2(N_p/N_m)(R_m/R_p)(T_m/T_p)(\mu_m/\mu_p)$$
$$= 50(1)^2(100/81.70)(53.34/96.33)(599.7/527.7) \times (41.79 \times 10^{-8}/22.70 \times 10^{-8}) = 70.90 \text{ lbf/in}^2(4.888 \times 10^5 \text{ N/m}^2)$$

See Sec. 14 for specific information on pump and compressor similarity.

Liquid Surfaces Considered in this category are ships, seaplanes during takeoff, submarines partly submerged, piers, dams, rivers, open-channel flow, spillways, harbors, etc. Resistance at liquid surfaces is due to surface tension and wave action. Since wave action is due to gravity, the gravity force and surface-tension force are now added to the forces that were considered in the last paragraph. These are expressed as the square root of the inertia/gravity force ratio or **Froude number** $\mathbf{F} = V/\sqrt{Lg}$ and as the inertia/surface tension force ratio or **Weber number** $\mathbf{W} = \rho LV^2/\sigma$. On the other hand, elastic and pressure forces are now absent. Surface tension is a minor property in fluid mechanics and it normally exerts a negligible effect on wave formation *except* when the waves are small, say less than 1 in. Thus the effects of surface tension on the model might be considerable, but negligible on the prototype. This type of "scale effect" must be avoided. For accurate results, the inertia/surface tension force ratio or Weber number should be considered. It is never possible to have complete dynamic similarity of liquid surfaces unless the model and prototype are the same size, as shown in the following example.

EXAMPLE. An ocean vessel 500 ft long is to travel at a speed of 15 knots. A 1:25 model of this ship is to be tested in a towing tank using seawater at design temperature. Determine the model speed required for (1) wave-resistance similarity, (2) viscous or skin-friction similarity, (3) surface-tension similarity, and (4) the model size required for complete dynamic similarity.

1. *Speed for* ***Froude-number*** similarity

$$\mathbf{F}_m = \mathbf{F}_p = (V/\sqrt{Lg})_m = (V/\sqrt{Lg})_p$$

or

$$V_m = V_p\sqrt{L_m/L_p} = 15\sqrt{1/25} = 3 \text{ knots}$$

2. *Speed for* ***Reynolds-number*** similarity

$$\mathbf{R}_m = \mathbf{R}_p = (\rho LV/\mu)_m = (\rho LV/\mu)_p$$
$$V_m = V_p(\rho_p/\rho_m)(L_p/L_m)(\mu_m/\mu_p)$$
$$V_m = 15(1)(25/1)(1) = 375 \text{ knots}$$

3. *Speed for* ***Weber-number*** similarity

$$\mathbf{W}_m = \mathbf{W}_p = (\rho LV^2/\sigma)_m = (\rho LV^2/\sigma)_p$$
$$V_m = V_p\sqrt{(\rho_p/\rho_m)(L_p/L_m)(\sigma_m/\sigma_p)}$$
$$V_m = 15\sqrt{(1)(25)(1)} = 75 \text{ knots}$$

4. *Model size for complete similarity.* First try Reynolds and Froude similarity; let

$$V_m = V_p(\rho_p/\rho_m)(L_p/L_m)(\mu_m/\mu_p) = V_p\sqrt{L_m/L_p}$$

which reduces to

$$L_m/L_p = (\rho_p/\rho_m)^{2/3}(\mu_m/\mu_p)^{2/3}$$

Next try Weber and Froude similarity; let

$$V_m = V_p\sqrt{(\rho_p/\rho_m)(L_p/L_m)(\sigma_m/\sigma_p)} = V_p\sqrt{L_m/L_p}$$

which reduces to

$$L_m/L_p = (\rho_p/\rho_m)^{1/2}(\sigma_m/\sigma_p)^{1/2}$$

For the same fluid at the same temperature, either of the above solves for $L_m = L_p$, or the model must be the same size as the prototype. For use of different fluids and/or the same fluid at different temperatures.

$$L_m/L_p = (\rho_p/\rho_m)^{2/3}(\mu_m/\mu_p)^{2/3} = (\rho_p/\rho_m)^{1/2}(\sigma_m/\sigma_p)^{1/2}$$

which reduces to

$$(\mu^4/\rho\sigma^3)_m = (\mu^4/\rho\sigma^3)_p$$

No practical way has been found to model for complete similarity. Marine engineering practice is to model for wave resistance and correct for skin-friction resistance. See Sec. 11.3.

DIMENSIONAL ANALYSIS

Dimensional analysis is the mathematics of dimensions and quantities and provides procedural techniques whereby the variables that are assumed to be significant in a problem can be formed into dimensionless parameters, the number of parameters being less than the number of variables. This is a great advantage, because fewer experimental runs are then required to establish a relationship between the parameters than between the variables. While the user is not presumed to have any knowledge of the fundamental physical equations, the more knowledgeable the user, the better the results. If any significant variable or variables are omitted, the relationship obtained from dimensional analysis will not apply to the physical problem. On the other hand, inclusion of all possible variables will result in losing the principal advantage of dimensional analysis, i.e., the reduction of the amount of experimental data required to establish relationships. Two formal methods of dimensional analysis are used, the **method of Lord Rayleigh** and **Buckingham's II theorem.**

Dimensions used in mechanics are mass M, length L, time T, and force F. Corresponding **units** for these dimensions are the slug (kilogram), the foot (metre), the second (second), and the pound force (newton). Any system in mechanics can be defined by three fundamental dimensions. Two systems are used, the force (*FLT*) and the mass (*MLT*). In the force system, mass is a derived quantity and in the mass system, force is a derived quantity. Force and mass are related by Newton's law: $F = MLT^{-2}$ and $M = FL^{-1}T^2$. Table 3.3.8 shows common variables and their dimensions and units.

Lord Rayleigh's method uses algebra to determine interrelationships among variables. While this method may be used for any number of variables, it becomes relatively complex and is not generally used for more than four. This method is most easily described by example.

EXAMPLE. In laminar flow, the unit shear stress τ is some function of the fluid dynamic viscosity μ, the velocity difference dU between adjacent laminae separated by the distance dy. Develop a relationship.

1. Write a functional relationship of the variables:

$$\tau = f(\mu, dU, \mathbf{dy})$$

Assume $\tau = K(\mu^a\, dU^b\, dy^c)$.

2. Write a dimensional equation in either *FLT* or *MLT* system:

$$(FL^{-2}) = K(FL^{-2}T)^a(LT^{-1})^b(L)^c$$

3. Solve the dimensional equation for exponents:

		τ	μ	dU	dy
Force	F	1 =	a	+ 0	+ 0
Length	L	−2 =	−2a	+ b	+ c
Time	T	0 =	a	− b	+ 0

Solution: $a = 1, b = 1, c = -1$

4. Insert exponents in the functional equation: $\tau = K(\mu^a\, dU^b\, dy^c) = K(\mu^1\, du^1\, dy^{-1})$, or $K = (\mu\, dU/\tau\, dy)$. This was based on the assumption of $\tau = K(\mu^a\, dU^b\, dy^c)$. The general relationship is $K = f(\mu\, dU/\tau\, dy)$. The functional relationship cannot be obtained from dimensional analysis. Only physical analysis and/or experiments can determine this. From both physical analysis and experimental data,

$$\tau = \mu\, dU/dy$$

The Buckingham II theorem serves the same purpose as the method of Lord Rayleigh for deriving equations expressing one variable in terms of its dependent variables. The II theorem is preferred when the number of variables exceeds four. Application of the II theorem results in the formation of dimensionless parameters called π ratios. These π ratios have no relation to 3.14159. . . . The II theorem will be illustrated in the following example.

EXAMPLE. Experiments are to be conducted with gas bubbles rising in a still liquid. Consider a gas bubble of diameter D rising in a liquid whose density is ρ, surface tension σ, viscosity μ, rising with a velocity of V in a gravitational field of g. Find a set of parameters for organizing experimental results.

1. List all the physical variables considered according to type: geometric, kinematic, or dynamic.

Table 3.3.8 Dimensions and Units of Common Variables

Symbol	Variable	Dimensions MLT	Dimensions FLT	Units USCS*	Units SI
		Geometric			
L	Length	L		ft	m
A	Area	L^2		ft^2	m^2
V	Volume	L^3		ft^3	m^3
		Kinematic			
t	Time	T		s	s
ω	Angular velocity	T^{-1}		s^{-1}	s^{-1}
f	Frequency				
V	Velocity	LT^{-1}		ft/s	m/s
ν	Kinematic viscosity	L^2T^{-1}		ft^2/s	m^2/s
Q	Volume flow rate	L^3T^{-1}		ft^3/s	m^3/s
α	Angular acceleration	T^{-2}		s^{-2}	s^2
a	Acceleration	LT^{-2}		ft/s^{-2}	m/s^2
		Dynamic			
ρ	Density	ML^{-3}	$FL^{-4}T^2$	slug/ft^3	kg/m^3
M	Mass	M	$FL^{-1}T^2$	slug	kg
I	Moment of inertia	ML^2	FLT^2	slug · ft^3	kg · m^2
μ	Dynamic viscosity	$ML^{-1}T^{-1}$	$FL^{-2}T$	slug/ft · s	kg/m · s
M	Mass flow rate	MT^{-1}	$FL^{-1}T^{-1}$	slug/s	kg/s
MV	Momentum	MLT^{-1}	FT	lbf · s	N · s
Ft	Impulse				
$M\omega$	Angular momentum	ML^2T^{-1}	FLT	slug · ft^2/s	kg · m^2/s
γ	Specific weight	$ML^{-2}T^{-2}$	FL^{-3}	lbf/ft^3	N/m^3
p	Pressure				
τ	Unit shear stress	$ML^{-1}T^{-2}$	FL^{-2}	lbf/ft^2	N/m^2
E	Modulus of elasticity				
σ	Surface tension	MT^{-2}	FL^{-1}	lbf/ft	N/m
F	Force	MLT^{-2}	F	lbf	N
E	Energy				
W	Work	ML^2T^{-2}	FL	lbf · ft	J
FL	Torque				
P	Power	ML^2T^{-3}	FLT^{-1}	lbf · ft/s	W
v	Specific volume	$M^{-1}L^3$	$F^{-1}L^4T^{-2}$	ft^3/lbm	m^3/kg

*United States Customary System.

2. Choose either the *FLT* or *MLT* system of dimensions.
3. Select a "basic group" of variables characteristic of the flow as follows:

   a. B_G, a geometric variable
   b. B_K, a kinematic variable
   c. B_D, a dynamic variable (if three dimensions are used)

4. Assign A numbers to the remaining variables starting with A_1.

Type	*Symbol*	*Description*	*Dimensions*	*Number*
Geometric	D	Bubble diameter	L	B_G
Kinematic	V	Bubble velocity	LT^{-1}	B_K
	g	Acceleration of gravity	LT^{-2}	A_1
Dynamic	ρ	Liquid density	ML^{-3}	B_D
	σ	Surface tension	MT^{-2}	A_2
	μ	Liquid viscosity	$ML^{-1}T^{-1}$	A_3

5. Write the basic equation for each π ratio as follows:

$$\pi_1 = (B_G)^{x1}(B_K)^{y1}(B_D)^{z1}(A_1)$$
$$\pi_2 = (B_G)^{x2}(B_K)^{y2}(B_D)^{z2}(A_2) \ldots \pi_n = (B_G)^{xn}(B_K)^{yn}(B_D)^{zn}(A_n)$$

Note that the number of π ratios is equal to the number of A numbers and thus equal to the number of variables less the number of fundamental dimensions in a problem.

6. Write the dimensional equations and use the algebraic method to determine the value of exponents x, y, and z for each π ratio. Note that for all π ratios, the sum of the exponents of a given dimension is zero.

$$\pi_1 = (B_G)^{x1}(B_K)^{y1}(B_D)^{z1}(A_1) = (D)^{x1}(V)^{y1}(\rho)^{z1}(g)$$
$$(M^0L^0T^0) = (L^{x1})(L^{y1}T^{-y1})(M^{z1}L^{-3z1})(LT^{-2})$$

Solution: $x_1 = 1, y_1 = -2, z_1 = 0$

$$\pi_1 = D^1V^{-2}\rho^0 g = Dg/V^2$$
$$\pi_2 = (B_G)^{x2}(B_K)^{y2}(B_D)^{z2}(A_2) = (D)^{x2}(V)^{y2}(\rho)^{z2}(\sigma)$$
$$(M^0L^0T^0) = (L^{x2})(L^{y2}T^{-y2})(M^{z2}L^{-3z2})(MT^{-2})$$

Solution: $x_2 = -1, y_2 = -2, z_2 = -1$

$$\pi_2 = D^{-1}V^{-2}\rho^{-1}\sigma = \sigma/DV^2\rho$$
$$\pi_3 = (B_G)^{x3}(B_K)^{y3}(B_D)^{z3}(A_3) = (D)^{x3}(V)^{y3}(\rho)^{z3}(\mu)$$
$$(M^0L^0T^0) = (L^{x3})(L^{y3}T^{-y3})(M^{z3}L^{-3z3})(ML^{-1}T^{-1})$$

Solution: $x_3 = -1, y_3 = -1, z_3 = -1$

$$\pi_3 = D^{-1}V^{-1}\rho^{-1}\mu = \mu/DV\rho$$

7. Convert π ratios to conventional practice. One statement of the Buckingham II theorem is that any π ratio may be taken as a function of all the others, or $f(\pi_1, \pi_2, \pi_3, \ldots, \pi_n) = 0$. This equation is mathematical shorthand for a functional statement. It could be written, for example, as $\pi_2 = f(\pi_1, \pi_3, \ldots, \pi_n)$. This equation states that π_2 is some function of π_1 and π_3 through π_n but is not a statement of *what* function π_2 is of the other π ratios. This can be determined only by physical and/or experimental analysis. Thus we are free to substitute *any* function in the equation; for example, π_1 may be replaced with $2\pi_1^{-1}$or π_n with $a\pi_n^b$.

The procedures set forth in this example are designed to produce π ratios containing the same terms as those resulting from the application of the principles of similarity so that the physical significance may be understood. However, any other combinations might have been used. The only real requirement for a "basic group" is that it contain the same number of terms as there are dimensions in a problem and that each of these dimensions be represented in it.

The π ratios derived for this example may be converted into conventional practice as follows:

$$\pi_1 = Dg/V^2$$

is recognized as the inverse of the square root of the Froude number **F**

$$\pi_2 = \sigma/DV^2\rho$$

is the inverse of the Weber number **W**

$$\pi = \mu/DV\rho$$

is the inverse of the Reynolds number **R**

Let $\pi_1 = f(\pi_2, \pi_3)$
Then $V = K(Dg)^{1 \div 2}$
where $K = f(\mathbf{W}, \mathbf{R})$

This agrees with the results of the dynamic-similarity analysis of liquid surfaces. This also permits a reduction in the experimental program from variations of six variables to three dimensionless parameters.

FORCES OF IMMERSED OBJECTS

Drag and Lift When a fluid impinges on an object as shown in Fig. 3.3.20, the undisturbed fluid pressure p and the velocity V change. Writing Bernoulli's equation for two points on the surface of the object, the point S being the most forward point and point A being any other point, we have, for horizontal flow,

$$p + \rho V^2/2 = p_S + \rho V_S^2/2 = p_A + \rho V_A^2/2$$

At point S, $V_S = 0$, so that $p_S = p + \rho V^2/2$. This is called the **stagnation** point, and p_S is the **stagnation pressure.** Since point A is any other point, the result of the fluid impingement is to create a pressure $p_A = p + \rho(V^2 - V_A^2)/2$ acting normal to every point on the surface of the object.

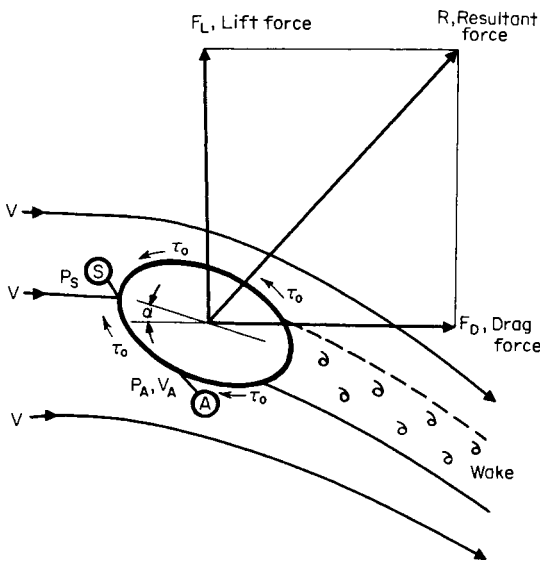

Fig. 3.3.20 Notation for drag and lift.

In addition, a frictional force $F_f = \tau_0 A_s$ tangential to the surface area A_s opposes the motion. The sum of these forces gives the resultant force R acting on the body. The resultant force R is resolved into the **drag** component F_D parallel to the flow and **lift** component F_L perpendicular to the fluid motion. Depending upon the shape of the object, a wake may be formed which sheds eddies with a frequency of f. The angle α is called the angle of attack. (See Secs. 11.4 and 11.5.)

From dimensional analysis or dynamic similarity,

$$f(\mathbf{C}_p, \mathbf{R}, \mathbf{M}, \mathbf{S}) = 0$$

The formation of a wake depends upon the Reynolds number, or $\mathbf{S} = f(\mathbf{R})$. This reduces the functional relation to $f(\mathbf{C}_p, \mathbf{R}, \mathbf{M}) = 0$. Since the drag and lift forces may be considered independently,

$$F_D = C_D\rho V^2(A)/2$$

where $C_D = f(\mathbf{R}, \mathbf{M})$, and A = characteristic area.

$$F_L = C_L\rho V^2(A)/2$$

where $C_L = f(\mathbf{R}, \mathbf{M})$.

It is evident from Fig. 3.3.20 that C_D and C_L are also functions of the angle of attack. Since the drag force arises from two sources, the pressure or shape drag F_p and the skin-friction drag F_f due to wall shear stress τ_0, the drag coefficient is made up of two parts:

$$F_D = F_p + F_f = C_D\rho AV^2/2 = C_p\rho AV^2/2 + C_f\rho A_s V^2/2$$

or $$C_D = C_p + C_f A_s/A$$

where C_p is the coefficient of pressure, C_f the skin-friction coefficient, and A_s the characteristic area for shear.

Skin-Friction Drag Figure 3.3.21 shows a fluid approaching a smooth flat plate with a uniform velocity profile of V. As the fluid passes over the plate, the velocity at the plate surface is zero and increases to V at some distance δ from the surface. The region in which the velocity varies from 0 to V is called the **boundary layer.** For some

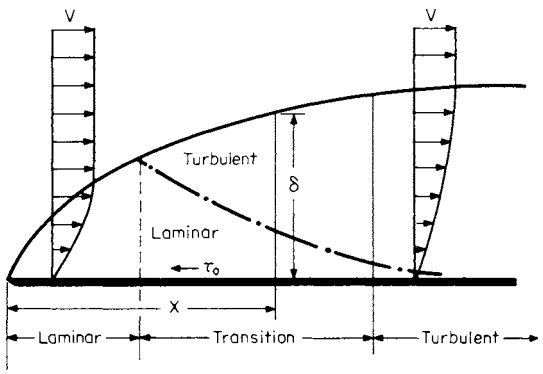

Fig. 3.3.21 Boundary layer along a smooth flat plate.

distance along the plate, the flow within the boundary layer is laminar, with viscous forces predominating, but in the transition zone as the inertia forces become larger, a turbulent layer begins to form and increases as the laminar layer decreases.

Boundary-layer thickness and skin-friction drag for incompressible flow over smooth flat plates may be calculated from the following equations, where $\mathbf{R}_X = \rho VX/\mu$:

Laminar

$\delta/X = 5.20\,\mathbf{R}_X^{-1/2}$ $\quad 0 < \mathbf{R}_X < 5 \times 10^5$
$C_f = 1.328\,\mathbf{R}_X^{-1/2}$ $\quad 0 < \mathbf{R}_X < 5 \times 10^5$

Turbulent

$\delta/X = 0.377\,\mathbf{R}_X^{-1/5}$ $\quad 5 \times 10^4 < \mathbf{R}_X < 10^6$
$\delta/X = 0.220\,\mathbf{R}_X^{-1/6}$ $\quad 10^6 < \mathbf{R}_X < 5 \times 10^8$
$C_f = 0.0735\,\mathbf{R}_X^{-1/5}$ $\quad 2 \times 10^5 < \mathbf{R}_X < 10^7$
$C_f = 0.455\,(\log_{10}\mathbf{R}_X)^{-2.58}$ $\quad 10^7 < \mathbf{R}_X < 10^8$
$C_f = 0.05863\,(\log_{10}C_f R_X)^{-2}$ $\quad 10^8 < \mathbf{R}_x < 10^9$

Transition The Reynolds number at which the boundary layer changes depends upon the roughness of the plate and degree of turbulence. The generally accepted number is 500,000, but the transition can take place at Reynolds numbers higher or lower. (Refer to Secs. 11.4 and 11.5.) For transition at any Reynolds number $\mathbf{R}_X$,

$$C_f = 0.455\,(\log_{10}\mathbf{R}_X)^{-2.58} - (0.0735\,\mathbf{R}_t^{4/5} - 1.328\,8\,\mathbf{R}_t^{1/2})\,\mathbf{R}_X^{-1}$$

For $\mathbf{R}_t = 5 \times 10^5$, $C_f = 0.455\,(\log_{10}\mathbf{R}_X)^{-2.58} - 1{,}725\,\mathbf{R}_X^{-1}$.

Pressure Drag Experiments with sharp-edged objects placed perpendicular to the flow stream indicate that their drag coefficients are essentially constant at Reynolds numbers over 1,000. This means that the drag for $\boldsymbol{R}_X > 10^3$ is pressure drag. Values of C_D for various shapes are given in Sec. 11 along with the effects of Mach number.

Wake Frequency An object in a fluid stream may be subject to the downstream periodic shedding of vortices from first one side and then the other. The frequency of the resulting transverse (lift) force is a function of the stream Strouhal number. As the wake frequency approaches the natural frequency of the structure, the periodic lift force increases asymptotically in magnitude, and when resonance occurs, the structure fails. Neglecting to take this phenomenon into account in design has been responsible for failures of electric transmission lines, submarine periscopes, smokestacks, bridges, and thermometer wells. The wake-frequency characteristics of **cylinders** are shown in Fig. 3.3.22. At a Reynolds number of about 20, vortices begin to shed alternately. Behind the cylinder is a staggered stable arrangement of vortices known as the "Kármán vortex trail." At a Reynolds number of about 10^5, the flow changes from laminar to turbulent. At the end of the transition zone ($\mathbf{R} \approx 3.5 \times 10^5$), the flow becomes turbulent, the alternate

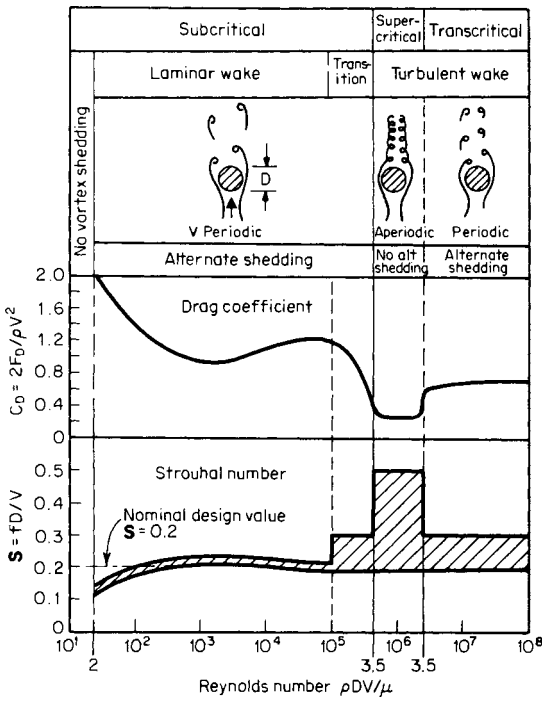

Fig. 3.3.22 Flow around a cylinder. (*From Murdock, "Fluid Mechanics and Its Applications," Houghton Mifflin, 1976.*)

shedding stops, and the wake is aperiodic. At the end of the supercritical zone ($\mathbf{R} \approx 3.5 \times 10^6$), the wake continues to be turbulent, but the shedding again becomes alternate and periodic.

The alternating **lift force** is given by

$$F_L(t) = C_L \rho V^2 A \sin(2\pi f t)/2$$

where t is the time. For an analysis of this force in the subcritical zone, see Belvins (Murdock, "Fluid Mechanics and Its Applications," Houghton Mifflin, 1976). For design of steel stacks, Staley and Graven (ASME 72PET/30) recommend $C_L = 0.8$ for $10^4 < \mathbf{R} < 10^5$, $C_L = 2.8 - 0.4 \log_{10} \mathbf{R}$ for $\mathbf{R} = 10^5$ to 10^6, and $C_L = 0.4$ for $10^6 < \mathbf{R} < 10^7$.

The **Strouhal number** is nearly constant to $\mathbf{R} = 10^5$, and a nominal design value of 0.2 is generally used. Above $\mathbf{R} = 10^5$, data from different experimenters vary widely, as indicated by the crosshatched zone of Fig. 3.3.22. This wide zone is due to experimental and/or measurement difficulties and the dependence on surface roughness to "'trigger" the boundary layer. Examination of Fig. 3.3.22 indicates an inverse relation of Strouhal number to drag coefficient.

Observation of actual structures shows that they vibrate at their natural frequency and with a mode shape associated with their fundamental (first) mode during vortex excitation. Based on observations of actual stacks and wind-tunnel tests, Staley and Graven recommend a constant Strouhal number of 0.2 for all ranges of Reynolds number. The ASME recommends $\mathbf{S} = 0.22$ for thermowell design ("Temperature Measurement," PTC 19.3). Until such time as the value of the Strouhal number above $\mathbf{R} = 10^5$ has been firmly established, designers of structures in this area should proceed with caution.

FLOW IN PIPES

Parameters for Pipe Flow The forces acting on a fluid flowing through and completely filling a horizontal pipe are inertia, viscous, pressure, and elastic. If the surface roughness of the pipe is ε, either similarity or dimensional analysis leads to $\mathbf{C}_p = f(\mathbf{R}, \mathbf{M}, L/D, \varepsilon/D)$, which may be written for incompressible fluids as $\Delta p = \mathbf{C}_p V^2/2 = K\rho V^2/2$, where K is the **resistance coefficient** and ε/D the **relative roughness** of the pipe surface, and the resistance coefficient $K = f(\mathbf{R}, L/D, \varepsilon/D)$. The pressure loss may be converted to the terms of **lost head:** $h_f = \Delta p/\gamma = KV^2/2g$. Conventional practice is to use the **friction factor** f, defined as $f = KD/L$ or $h_f = KV^2/2g = (fL/D)V^2/2g$, where $f = f(\mathbf{R}, \varepsilon/D)$. When a fluid flows into a pipe, the boundary layer starts at the entrance, as shown in Fig. 3.3.23, and grows continuously until it fills the pipe. From the equation of motion $dh_f = \tau\, dL/\gamma R_h$ and for circular ducts $R_h = D/4$. Comparing wall shear stress τ_0 with friction factor results in the following: $\tau_0 = f\rho V^2/8$.

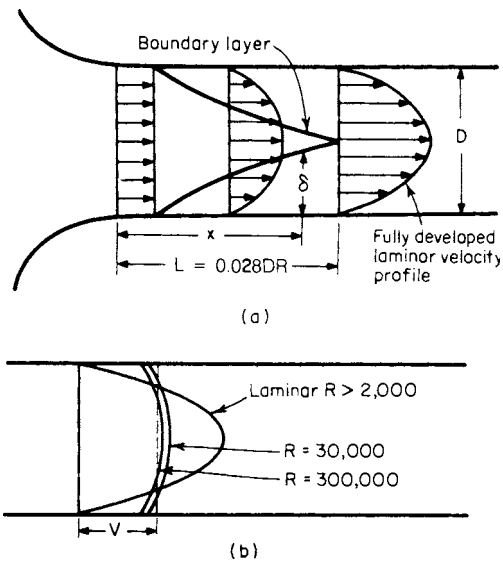

Fig. 3.3.23 Velocity profiles in pipes.

Laminar Flow In this type of flow, the resistance is due to viscous forces only so that it is independent of the pipe surface roughness, or $\tau_0 = \mu\, dU/dy$. Application of this equation to the equation of motion and the friction factor yields $f = 64/\mathbf{R}$. Experiments show that it is possible to maintain laminar flow to very high Reynolds numbers if care is taken to increase the flow gradually, but normally the slightest disturbance will destroy the laminar boundary layer if the value of Reynolds number is greater than 4,000. In a like manner, flow initially turbulent

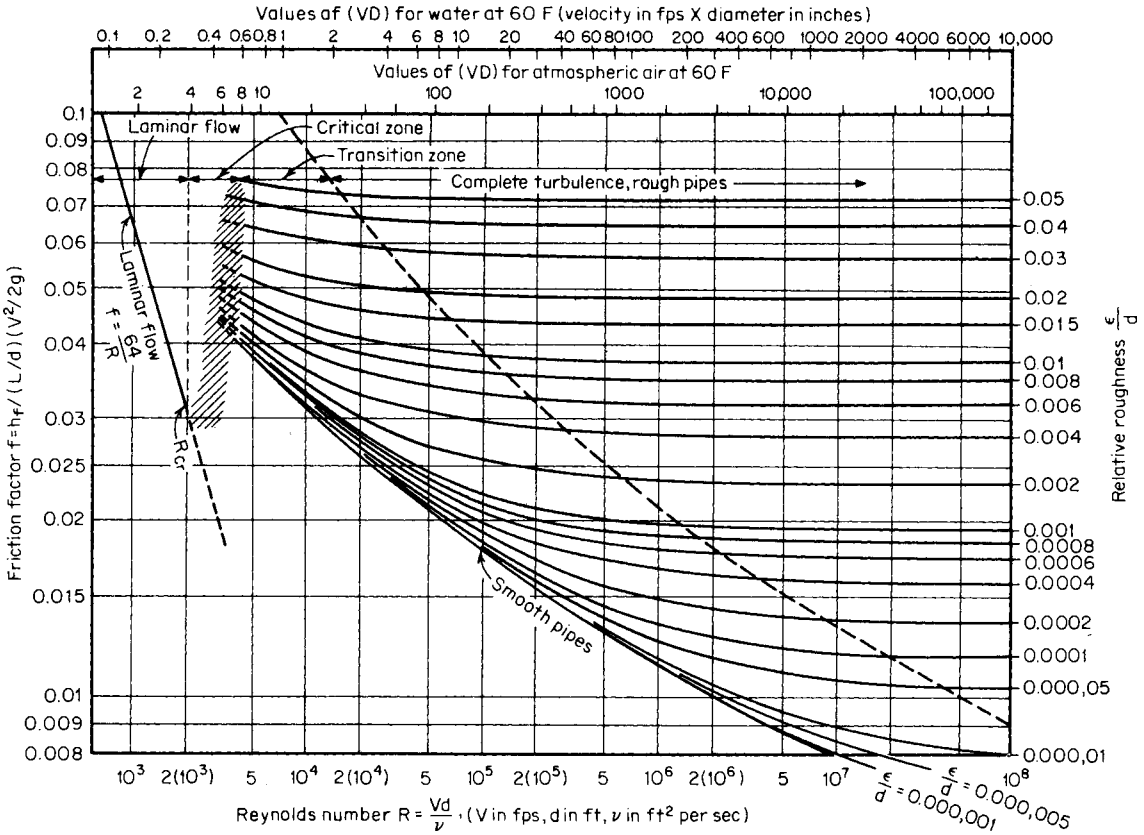

Fig. 3.3.24 Friction factors for flow in pipes.

can be maintained with care to very low Reynolds numbers, but the slightest upset will result in laminar flow if the Reynolds number is less than 2,000. The Reynolds-number range between 2,000 and 4,000 is called the **critical zone** (Fig. 3.3.24). Flow in the zone is **unstable,** and designers of piping systems must take this into account.

EXAMPLE. Glycerin at 68°F (20°C) flows through a horizontal pipe 1 in in diameter and 20 ft long at a rate of 0.090 lbm/s. What is the pressure loss? From the continuity equation $V = Q/A = (m/\rho g)/(\pi D^2/4) = [0.090/(2.447 \times 32.17)]/[(\pi/4)(1/12)^2] = 0.2096$ ft/s. The Reynolds number $\mathbf{R} = \rho VD/\mu = (2.447)(0.2096)(1/12)/(29{,}500 \times 10^{-6}) = 1.449$. $\mathbf{R} < 2{,}000$; therefore, flow is laminar and $f = 64/\mathbf{R} = 64/1.449 = 44.17$. $K = fL/D = 44.17 \times 20(1/12) = 10{,}600$. $\Delta p = K\rho V^2/2 = 10{,}600 \times 2.447\ (0.2096)^2/2 = 569.8$ lbf/ft^2 = 569.8/144 = 3.957 lbf/in^2 (2.728×10^4 N/m^2).

Turbulent Flow The friction factor for Reynolds number over 4,000 is computed using the Colebrook equation:

$$\frac{1}{\sqrt{f}} = -2 \log_{10}\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\mathbf{R}\sqrt{f}}\right)$$

Figure 3.3.24 is a graphical presentation of this equation (Moody, *Trans. ASME,* 1944, pp. 671–684). Examination of the Colebrook equation indicates that if the value of surface roughness ε is small compared with the pipe diameter ($\varepsilon/D \to 0$), the friction factor is a function of Reynolds number only. A **smooth pipe** is one in which the ratio $(\varepsilon/D)/3.7$ is small compared with $2.51/\mathbf{R}\sqrt{f}$. On the other hand, as the Reynolds number increases so that $2.51/\mathbf{R}\sqrt{f} \to 0$, the friction factor becomes a function of relative roughness only and the pipe is called a **rough pipe.** Thus the same pipe may be smooth under one flow condition, and rough under another. The reason for this is that as the Reynolds number increases, the thickness of the laminar sublayer decreases as shown in Fig. 3.3.21, exposing the surface roughness to flow. Values of absolute roughness ε are given in Table 3.3.9. The variation of friction factor shown in Fig. 3.3.9 is for new, clean pipes. The change of friction factor with **age** depends upon the chemical properties of the fluid and the piping material. Published data for flow of water through wrought-iron or cast-iron pipes show as much as 20 percent increase after a few months to 500 percent after 20 years. When necessary to allow for service life, a study of specific conditions is recommended. The calculation of friction factor to four significant figures in the examples to follow is only for numerical comparison and should not be construed to mean accuracy.

Table 3.3.9 Values of Absolute Roughness, New Clean Commercial Pipes

Type of pipe or tubing	ε ft (0.3048 m) $\times 10^{-6}$ Range	Design	Probable max variation of f from design, %
Asphalted cast iron	400	400	−5 to + 5
Brass and copper	5	5	−5 to + 5
Concrete	1,000 10,000	4,000	−35 to 50
Cast iron	850	850	−10 to + 15
Galvanized iron	500	500	0 to + 10
Wrought iron	150	150	−5 to 10
Steel	150	150	−5 to 10
Riveted steel	3,000 30,000	6,000	−25 to 75
Wood stave	600 3,000	2,000	−35 to 20

SOURCE: Compiled from data given in "Pipe Friction Manual," Hydraulic Institute, 3d ed., 1961.

Engineering Calculations Engineering pipe computations usually fall into one of the following classes:

1. Determine pressure loss Δp when Q, L, and D are known.
2. Determine flow rate Q when L, D, and Δp are known.
3. Determine pipe diameter D when Q, L, and Δp are known.

Pressure-loss computations may be made to engineering accuracy using an expanded version of Fig. 3.3.24. Greater precision may be obtained by using a combination of Table 3.3.9 and the Colebrook equation, as will be shown in the example to follow. Flow rate may be determined by direct solution of the Colebrook equation. Computation of pipe diameter necessitates the trial-and-error method of solution.

EXAMPLE. *Case 1:* 2,000 gal/min of 68°F (20°C) water flow through 500 ft of cast-iron pipe having an internal diameter of 10 in. At point 1 the pressure is 10 lbf/in^2 and the elevation 150 ft, and at point 2 the elevation is 100 ft. Find p_2.

From continuity $V = Q/A = [2{,}000 \times (231/1{,}728)/60]/[(\pi/4)(10/12)^2] = 8.170$ ft/s. Reynolds number $\mathbf{R} = \rho VD/\mu = (1.937)(8.170)(10/12)/(20.92 \times 10^{-6}) = 6.304 \times 10^5$. $\mathbf{R} > 4{,}000$ ∴ flow is turbulent. $\varepsilon/D = (850 \times 10^{-6})/(10/12) = 1.020 \times 10^{-3}$.

Determine f: from Fig. 3.3.24 by interpolation $f = 0.02$. Substituting this value on the right-hand side of the Colebrook equation,

$$\frac{1}{\sqrt{f}} = -2\log_{10}\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\mathbf{R}\sqrt{f}}\right)$$

$$= -2\log_{10}\left[\frac{1.020 \times 10^{-3}}{3.7} + \frac{2.51}{(6.305 \times 10^5)\sqrt{0.02}}\right]$$

$$\frac{1}{\sqrt{f}} = 7.035 \qquad f = 0.02021$$

Resistance coefficient $K = \dfrac{fL}{D} = \dfrac{0.02021 \times 500}{10/12}$

$$K = 12.13$$
$$h_{1/2} = KV^2/2g = 12.13 \times (8.170)^2/2 \times 32.17$$
$$h_{1/2} = 12.58 \text{ ft}$$

Equation of motion: $p_1/\gamma + V_1^2/2g + z_1 = p_2/\gamma + V_2^2/2g + z_2 + h_{1/2}$. Noting that $V_1 = V_2 = V$ and solving for p_2,

$$p_2 = p_1 + \gamma(z_1 - z_2 - h_{1/2})$$
$$= 144 \times 10 + (1.937 \times 32.17)(150 - 100 - 12.58)$$
$$p_2 = 3{,}772 \text{ lbf/ft}^2 = 3{,}772/144 = 26.20 \text{ lbf/in}^2\ (1.806 \times 10^5 \text{ N/m}^2)$$

EXAMPLE. *Case 2:* Gasoline (sp. gr. 0.68) at 68°F (20°C) flows through a 6-in schedule 40 (ID = 0.5054 ft) welded steel pipe with a head loss of 10 ft in 500 ft. Determine the flow. This problem may be solved directly by deriving equations that do not contain the flow rate Q.

$$\text{From } h_f = \left(\frac{fL}{D}\right)\frac{V^2}{2g}, \qquad V = (2gh_fD)^{1/2}(fL)^{1/2}$$

$$\text{From } \mathbf{R} = \rho VD/\mu, \qquad V = \mathbf{R}\mu/\rho D$$

Equating the above and solving,

$$\mathbf{R}\sqrt{f} = (\rho D/\mu)(2gh_fD/L)^{1/2}$$
$$= (1.310 \times 0.5054/5.98 \times 10^{-6})$$
$$\times (2 \times 32.17 \times 10 \times 0.5054/500)^{1/2} = 89{,}285$$

which is now in a form that may be used directly in the Colebrook equation:

$$\varepsilon/D = 150 \times 10^{-6}/0.5054 = 2.968 \times 10^{-4}$$

From the Colebrook equation,

$$\frac{1}{\sqrt{f}} = -2\log_{10}\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\mathbf{R}\sqrt{f}}\right)$$

$$= -2\log_{10}\left(\frac{2.968 \times 10^{-4}}{3.7} + \frac{2.51}{89{,}285}\right)$$

$$\frac{1}{\sqrt{f}} = 7.931 \qquad f = 0.01590$$

$$\mathbf{R} = 89{,}285/\sqrt{f} = 89{,}285 \times 7.93 = 7.08 \times 10^5$$
$$\mathbf{R} > 4{,}000 \text{ ∴ flow is turbulent}$$
$$V = \mathbf{R}\mu/\rho D = (7.08 \times 10^5 \times 5.98 \times 10^{-6})/(1.310 \times 0.5054) = 6.396 \text{ ft/s}$$
$$Q = AV = (\pi/4)(0.5054)^2(6.396)$$
$$Q = 1.283 \text{ ft}^3\text{/s}\ (3.633 \times 10^{-2} \text{ m}^3\text{/s}^1)$$

EXAMPLE. *Case 3:* Water at 68°F (20°C) is to flow at a rate of 500 ft^3/s through a concrete pipe 5,000 ft long with a head loss not to exceed 50 ft. Determine the diameter of the pipe. This problem may be solved by trial and error using methods of the preceding example. First trial: Assume any diameter (say 1 ft).

$$\mathbf{R}\sqrt{f} = (\rho D/\mu)(2gh_fD/L)^{1/2}$$
$$= (1.937D/20.92 \times 10^{-6}) \times (2 \times 32.17 \times 50D/5{,}000)^{1/2}$$
$$= 74{,}269D^{3/2} = 74{,}269(1)^{3/2} = 74{,}269$$
$$\varepsilon/D_1 = 4{,}000 \times 10^{-6}/D = 4{,}000 \times 10^{-6}/(1) = 4{,}000 \times 10^{-6}$$
$$\frac{1}{\sqrt{f_1}} = -2\log_{10}\left(\frac{\varepsilon/D_1}{3.7} + \frac{2.51}{\mathbf{R}\sqrt{f_1}}\right)$$
$$= -2\log_{10}\left(\frac{4{,}000 \times 10^{-6}}{3.7} + \frac{2.51}{74{,}269}\right)$$
$$\frac{1}{\sqrt{f_1}} = 5.906 \qquad f_1 = 0.02867$$
$$\mathbf{R}_1 = 74{,}269/\sqrt{f_1} = 74{,}269 \times 5.906 = 438{,}600$$
$$V_1 = \mathbf{R}\mu/\rho D_1 = (438{,}600 = 20.92 \times 10^{-6})/(1.937 \times 1)$$
$$V_1 = 4.737 \text{ ft/s}$$
$$Q_1 = A_1V_1 = [\pi(1)^2/4]4.737 = 3.720 \text{ ft}^3\text{/s}$$

For the same loss and friction factor,

$$D_2 = D_1(Q/Q_1)^{2/5} = (1)(500/3.720)^{2/5} = 7.102 \text{ ft}$$

For the second trial use $D_2 = 7.102$, which results in $Q = 502.2$ ft^3/s. Since the nearest standard size would be used, additional trials are unnecessary.

Velocity Profile Figure 3.3.23*a* shows the formation of a laminar velocity profile. As the fluid enters the pipe, the boundary layer starts at the entrance and grows continuously until it fills the pipe. The flow while the boundary is growing is called **generating flow.** When the boundary layer completely fills the pipe, the flow is called **established flow.** The distance required for establishing **laminar flow** is $L/D \approx 0.028\ \mathbf{R}$. For **turbulent flow,** the distance is much shorter because of the turbulence and not dependent upon Reynolds number, L/D being from 25 to 50.

Examination of Fig. 3.3.23*b* indicates that as the Reynolds number increases, the velocity distribution becomes "flatter" and the flow approaches **one-dimensional.** The velocity profile for laminar flow is parabolic, $U/V = 2[1 - (r/r_o)^2]$ and for **turbulent flow, logarithmic** (except for the very thin laminar boundary layer), $U/V = 1 + 1.43\sqrt{f} + 2.15\sqrt{f}\log_{10}(1 - r/r_o)$. The use of the average velocity produces an error in the computation of kinetic energy. If α is the **kinetic-energy correction factor,** the true kinetic-energy change per unit mass between two points on a flow system $\Delta KE = \alpha_1V_1^2/2g_c - \alpha_2V_2^2/2g_c$, where $\alpha = (1/AV^3)\int U^3dA$. For **laminar flow,** $\alpha = 2$ and for **turbulent flow,** $\alpha \approx 1 + 2.7f$. Of interest is the **pipe factor** V/U_{max}; for **laminar flow,** $V/U_{max} = 1/2$ and for **turbulent flow,** $V/U_{max} = 1 + 1.43\sqrt{f}$. The location at which the local velocity equals the average velocity for **laminar flow** is $U = V$ at $r/r_o = 0.7071$ and for **turbulent flow** is $U = V$ at $r/r_o = 0.7838$.

Compressible Flow At the present time, there are no true analytical solutions for the computation of actual characteristics of compressible fluids flowing in pipes. In the real flow of a compressible fluid in a pipe, the amount of heat transferred and its direction are dependent upon the amount of insulation, the temperature gradient between the fluid and ambient temperatures, and the heat-transfer coefficient. Each condition requires an individual application of the principles of thermodynamics and heat transfer for its solution.

Conventional engineering practice is to use one of the following methods for flow computation.

1. Assume **adiabatic** flow. This approximates the flow of compressible fluids in short, insulated pipelines.
2. Assume **isothermal** flow. This approximates the flow of gases in long, uninsulated pipelines where the fluid and ambient temperatures are nearly equal.

Adiabatic Flow If the Mach number is less than ¼, results within normal engineering-accuracy requirements may be obtained by considering the fluid to be incompressible. A detailed discussion of and methods for the solution of compressible adiabatic flow are beyond the scope of this section, and any standard gas-dynamics text should be consulted.

Isothermal Flow The equation of motion for a horizontal piping system may be written as follows:

$$dp + \rho V\,dV + \gamma\,dh_f = 0$$

noting, from the continuity equation, that $\rho V = M/A = G$, where G is the **mass velocity** in slugs/(ft^2)(s), and that $\gamma\,dh_f = [(f/D)\rho V^2/2]\,dL = [(f/D)GV/2]\,dL$. Substituting in the above equation of motion and dividing by $GV/2$ results in

$$\frac{2\rho\,dp}{G^2} + \frac{2dV}{V} + \left(\frac{F}{D}\right)dL = 0$$

Integrating for an isothermal process ($p/\rho = C$) and assuming f is a constant,

$$\frac{\rho_1 p_1}{G^2}\left[\left(\frac{p_2}{p_1}\right)^2 - 1\right] + 2\log_e\left(\frac{V_2}{V_1}\right) + \frac{fL}{D} = 0$$

Noting that $A_1 = A_2$, $V_2/V_1 = \rho_1/\rho_2 = p_1/p_2$, and solving for G,

$$G = \left\{\frac{\rho_1 p_1[1 - (p_2/p_1)^2]}{2\log_e(p_1/p_2) + fL/D}\right\}^{1/2}$$

The Reynolds number may be written as

$$\mathbf{R} = \frac{\rho VD}{\mu} = \frac{GD}{\mu} \quad \text{and} \quad G = \mathbf{R}\frac{\mu}{D}$$

The value of $\mathbf{R}\sqrt{f}$ may be obtained from the simultaneous solution of the two equations for G, assuming that $2\log_e p_1/p_2$ is small compared with fL/D.

$$\mathbf{R}\sqrt{f} \approx \left\{\frac{D^3\rho_1 p_1}{\mu^2 L}\left[1 - \left(\frac{p_2}{p_1}\right)\right]\right\}^{1/2}$$

EXAMPLE. Air at 68°F (20°C) is flowing isothermally through a horizontal straight standard 1-in steel pipe (inside diameter = 1.049 in). The pipe is 200 ft long, the pressure at the pipe inlet is 74.7 lbf/in^2, and the pressure drop through the pipe is 5 lbf/in^2. Find the flow rate in lbm/s. From the equation of state $\rho_1 = p/g_cRT = (144 \times 74.7)/(32.17 \times 53.34 \times 527.7) = 0.01188$ slugs/ft^3.

$$\mathbf{R}\sqrt{f} = \{[(D^3\rho_1 p_1/\mu^2 L)][1 - (p_2/p_1)^2]\}^{1/2} = \{[(1.049/12)^3(0.01188) \times (144 \times 74.7)/(39.16 \times 10^{-8})^2(200)[1 - (69.7/74.7)^2]\}^{1/2} = 18{,}977$$

For steel pipe $\varepsilon = 150 \times 10^{-6}$ ft, $\varepsilon/D = (150 \times 10^{-6})/(1.049/12) = 1.716 \times 10^{-3}$. From the Colebrook equation,

$$\frac{1}{\sqrt{f}} = -2\log_{10}\left(\frac{\varepsilon/D}{3.7} + \frac{2.51}{\mathbf{R}\sqrt{f}}\right) = 2\log_{10}[(1.716 \times 10^{-3}/3.7) + (2.51)/(18{,}977)] = 6.449$$

$$f = 0.02404$$

$$\mathbf{R} = (\mathbf{R}\sqrt{f})(1/\sqrt{f}) = (18{,}953)(6.449) = 122{,}200$$

$\mathbf{R} > 4{,}000 \therefore$ flow is turbulent

$$G = \left\{\frac{\rho_1 p_1[1 - (p_2/p_1)^2]}{2\log_e(p_1/p_2) + fL/D}\right\}^{1/2} = \left\{\frac{(0.01188)(144 \times 74.7)[1 - (69.7/74.7)^2]}{2\log_e(74.7/69.7) + (0.02404)(200)/(1.049/12)}\right\}^{1/2} = 0.5476 \text{ slug/(ft}^2\text{)(s)}$$

$$\dot{m} = g_c AG = (32.17)(\pi/4)(1.049/12)^2(0.5476)$$

$$\dot{m} = 0.1057 \text{ lbm/s } (47.94 \times 10^{-3} \text{ kg/s})$$

Noncircular Pipes For the flow of fluids in noncircular pipes, the **hydraulic diameter** D_h is used. From the definition of hydraulic radius, the diameter of a circular pipe was shown to be four times its **hydraulic radius;** thus $D_h = 4R_h$. The Reynolds number thus may be written as $\mathbf{R} = \rho VD_h/\mu = GD_h/\mu$, the relative roughness as ε/D_h, and the resistance coefficient $K = fL/D_h$. With the above modifications, flows through noncircular pipes may be computed in the same manner as for circular pipes.

EXAMPLE. Air at 68°F (20°C) and 100 lbf/in^2 enters a rectangular duct 1 by 3 ft at a rate of 720 lbm/s. The duct is horizontal, 100 ft long, and made of galvanized iron. Assuming isothermal flow, estimate the pressure loss due to friction in this line. From the equation of state, $\rho_1 = \rho_1/g_cRT_1 = (144 \times 100)/(32.17)(53.34)(527.7) = 0.01590$ slug/ft^3. From Table 3.3.6, $R_h = bD/2(b + D) = 3 \times 1/2(3 + 1) = 0.375$ ft, and $D_h = 4R_h = 4 \times 0.375 = 1.5$ ft. For galvanized iron, $\varepsilon/D_h = 500 \times 10^{-6}/1.5 = 3.333 \times 10^{-4}$

$$G = (\dot{m}/g_c)/A = (720/32.17)/(1 \times 3) = 7.460 \text{ slugs/(ft}^2\text{)(s)}$$

$$\mathbf{R} = GD_h/\mu = (7.460)(1.5)/(39.16 \times 10^{-8}) = 28{,}580{,}000 > 4{,}000 \therefore \text{ flow is turbulent}$$

From Fig. 3.3.24, $f \approx 0.015$

$$\frac{1}{\sqrt{f}} = -2\log_{10}\left(\frac{\varepsilon/D_h}{3.7} + \frac{2.51}{\mathbf{R}\sqrt{f}}\right) = -2\log_{10}\left(\frac{3.333 \times 10^{-4}}{3.7} + \frac{2.51}{28{,}580{,}000\sqrt{0.015}}\right)$$

$$f = 0.01530$$

Solving the isothermal equation for p_2/p_1,

$$\frac{p_2}{p_1} = \left\{1 - \left(\frac{G^2}{\rho_1 p_1}\right)\left[2\log_e\left(\frac{p_1}{p_2}\right) + \frac{fL}{D_h}\right]\right\}^{1/2}$$

For first trial, assume $2\log_e(p_1/p_2)$ is small compared with fL/D:

$$p_2/p_1 = \{1 - [(7.460)^2/(0.01590)(144 \times 100)][0 + (0.01530)(100)/1.5]\}^{1/2} = 0.8672$$

Second trial using first-trial values results in 0.8263. Subsequent trials result in a balance at $p_2/p_1 = 0.8036$, $p_2 = 100 \times 0.8036 = 80.36$ lbf/in^2 (5.541×10^5 N/m^2).

PIPING SYSTEMS

Resistance Parameters The resistance to flow of a piping system is similar to the resistance of an object immersed in a flow stream and is made up of pressure (inertia) or shape drag and skin-friction (viscous) drag. For long, straight pipes the pressure drag is characterized by the **relative roughness** ε/D and the skin friction by the **Reynolds number R.** For other piping components, two parameters are used to describe the resistance to flow, the **resistance coefficient** $K = fL/D$ and the **equivalent length** $L/D = K/f$. The resistance-coefficient method assumes that the component loss is all due to pressure drag and that the flow through the component is completely turbulent and independent of Reynold's number. The equivalent-length method assumes that resistance of the component varies in the same manner as does a straight pipe. The basic assumption then is that its pressure drag is the same as that for the relative roughness ε/D of the pipe and that the friction drag varies with the Reynolds number $\mathbf{R}$ in the same manner as the straight pipe. Both methods have the inherent advantage of simplicity in application, but neither is correct except in the fully developed turbulent region. Two excellent sources of information on the resistance of piping-system components are the Hydraulic Institute "Pipe Friction Manual," which uses the resistance-coefficient method, and the Crane Company Technical Paper 410 ("Fluid Meters," 6th ed. ASME, 1971), which uses the equivalent-length concept.

For valves, branch flow through tees, and the type of components listed in Table 3.3.10, the pressure drag is predominant, is "rougher" than the pipe to which it is attached, and will extend the completely turbulent region to lower values of Reynolds number. For bends and elbows, the loss is made up of pressure drag due to the change of direction and the consequent secondary flows which are dissipated in 50 diameters or more downstream piping. For this reason, loss through adjacent bends will not be twice that of a single bend.

In long pipelines, the effect of bends, valves, and fittings is usually negligible, but in systems where there is little straight pipe, they are the controlling factor. Under-design will result in the failure of the system to deliver the required capacity. Over-design will result in inefficient operation because it will be necessary to "throttle" one or more of the valves. For estimating purposes, Tables 3.3.10 and 3.3.11 may be used as shown in the examples. When available, the manufacturers' data should be used, particularly for valves, because of the wide variety of designs for the same type. (See also Sec. 12.4.)

Series Systems In a single piping system made of various sizes, the practice is to group all of one size together and apply the continuity equation, as shown in the following example.

EXAMPLE. Water at 68°F (20°C) leaves an open tank whose surface elevation is 180 ft and enters a 2-in schedule 40 steel pipe via a sharp-edged entrance. After 50 ft of straight 2-in pipe that contains a 2-in globe valve, the line enlarges suddenly to an 8-in schedule 40 steel pipe which consists of 100 ft of straight 8-in pipe, two standard 90° elbows and one 8-in angle valve. The 8-in line discharges below the surface of another open tank whose surface elevation is 100 ft. Determine the volumetric flow rate.

$$D_1 = 2.067/12 = 0.1723 \text{ ft} \quad \text{and} \quad D_2 = 7.981/12 = 0.6651 \text{ ft}$$
$$\varepsilon/D_1 = 150 \times 10^{-6}/0.1723 = 8.706 \times 10^{-4}$$
$$\varepsilon/D_2 = 150 \times 10^{-6}/0.6651 = 2.255 \times 10^{-4}$$

For turbulent flow,

$$\frac{1}{\sqrt{f_1}} = -2 \log_{10}\left(\frac{\varepsilon/D}{3.7}\right)$$

$$\frac{1}{\sqrt{f_1}} = -2 \log_{10}\left(\frac{8.706 \times 10^{-4}}{3.7}\right) \qquad f_1 = 0.01899$$
$$\frac{1}{\sqrt{f_1}} = -2 \log_{10}\left(\frac{2.255 \times 10^{-4}}{3.7}\right) \qquad f_2 = 0.01407$$

1. *2-in components*

	K
Entrance loss, sharp-edged	$= 0.5$
50 ft straight pipe $= f_1\,(50/0.1723)$	$= 290.2f_1$
Globe valve $= f_1\,(L/D)$	$= 450.0f_1$
Sudden enlargement $k = [-(D/D_2)^2]^2$ $= [1 - (2.067/7.981)^2]^2$	$= 0.87$
	$\Sigma K_1 = 1.37 + 740.2f_1$

2. *8-in components*

	K
100 ft of straight pipe f_2 (100/0.6651)	$= 150.4f_2$
2 standard 90° elbows $2 \times 30\,f_2$	$= 60\ f_2$
1 angle valve $200\,f_2$	$= 200\ f_2$
Exit loss	$= 1$
	$\Sigma K_2 = 1 + 410.4f_2$

3. *Apply equation of motion*

$$h_{1f2} = z_1 - z_2 = (\Sigma K_1)\frac{V_1^2}{2g} + (\Sigma K_2)\frac{V_2^2}{2g}$$

From continuity, $\rho_1 A_1 V_1 = \rho_2 A_2 V_2$ for $\rho_1 = \rho_2$

$$V_2 = V_1(A_1/A_2) = V_1(D_1/D_2)^2$$
$$h_{1f2} = z_1 - z_2 = [\Sigma K_1 + \Sigma K_2(D_1/D_2)^4]V_1^2/2g$$
$$V_1 = \{[2g(z_1 - z_2)]/[\Sigma K_1 + \Sigma K_2(D_1/D_2)^4]\}^{1/2}$$
$$V_1 = \left[\frac{2 \times 32.17 \times (180 - 100)}{(1.37 + 740.2f_1) + (1 + 410.4f_2)(2.067/7.981)^4}\right]^{1/2}$$
$$V_1 = \frac{71.74}{(1.374 + 740.2f_1 + 1.846f_2)^{1/2}}$$

4. For first trial assume f_1 and f_2 for complete turbulence

$$V_1 = \frac{71.74}{(1.374 + 740.2 \times 0.01899 + 1.846 \times 0.01407)^{1/2}}$$
$$V_1 = 18.25 \text{ ft/s}$$
$$V_2 = 18.25\,(2.067/7.981)^2 = 1.224 \text{ ft/s}$$
$$\mathbf{R}_1 = \rho_1 V_1 D_1/\mu = (1.937)(18.25)(0.1723)/(20.92 \times 10^{-6})$$
$$\mathbf{R}_1 = 291{,}100 > 4{,}000 \therefore \text{ flow is turbulent}$$
$$\mathbf{R}_2 = \rho_2 V_2 D_2/\mu_2 = (1.937)(1.224)(0.6651)/(20.92 \times 10^{-6})$$
$$\mathbf{R}_2 = 75{,}420 > 4{,}000 \therefore \text{ flow is turbulent}$$

5. For second trial use first trial V_1 and V_2. From Fig. 3.3.24 and the Colebrook equation,

$$\frac{1}{\sqrt{f_1}} = -2 \log_{10}\left(\frac{8.706 \times 10^{-4}}{3.7} + \frac{2.51}{291{,}100\sqrt{0.020}}\right)$$
$$f_1 = 0.02008$$
$$\frac{1}{\sqrt{f_2}} = -2 \log_{10}\left(\frac{2.255 \times 10^{-4}}{3.7} + \frac{2.51}{75{,}420\sqrt{0.020}}\right)$$
$$f_2 = 0.02008$$
$$V_1 = \frac{71.74}{(1.374 + 740.2 \times 0.02008 + 1.864 \times 0.02008)^{1/2}}$$
$$V_1 = 17.78$$

A third trial results in $V = 17.77$ ft/s or $Q = A_1 V_1 = (\pi/4)(0.1723)^2(17.77) = 0.4143 \text{ ft}^3/\text{s}$ $(0.173 \times 10^{-2} \text{ m}^3/\text{s})$.

Parallel Systems In solution of problems involving two or more parallel pipes, the head loss for all of the pipes is the same as shown in the following example.

EXAMPLE. Benzene at 68°F (20°C) flows at a rate of 0.5 ft³/s through two parallel straight, horizontal pipes connecting two pressurized tanks. The pipes are both schedule 40 steel, one being 1 in, the other 2 in. They both are 100 ft long and have connections that project inwardly in the supply tank. If the pressure in the supply tank is maintained at 100 lbf/in², what pressure should be maintained on the receiving tank?

$$D_1 = 1.049/12 = 0.08742 \text{ ft} \quad \text{and} \quad D_2 = 2.067/12 = 0.1723 \text{ ft}$$
$$\varepsilon/D_1 = 150 \times 10^{-6}/0.08742 = 1.716 \times 10^{-3}$$
$$\varepsilon/D_2 = 150 \times 10^{-6}/0.1723 = 8.706 \times 10^{-4}$$

For turbulent flow,

$$\frac{1}{\sqrt{f}} = -2\log_{10}\left(\frac{\varepsilon/D}{3.7}\right)$$

$$\frac{1}{\sqrt{f_1}} = -2\log_{10}\left(\frac{1.716\times10^{-3}}{3.7}\right) \qquad f_1 = 0.02249$$

$$\frac{1}{\sqrt{f_2}} = -2\log_{10}\left(\frac{8.706\times10^{-4}}{3.7}\right) \qquad f_1 = 0.01899$$

1. *1-in. components*	K
Entrance loss, inward projection	$= 1.0$
100 ft straight pipe f_1 (100/0.08742)	$= 1{,}144\,f_1$
Exit loss	$= 1.0$
	$\Sigma K_1 = 2.0 + 1{,}144\,f_1$

2. *2-in components*	
Entrance loss, inward projection	$= 1.0$
100 ft straight nine f_2 (100/0.1723)	$= 580.4\,f_2$
Exit loss	$= 1.0$
	$\Sigma K_2 = 2.0 + 580.4\,f_2$

$$h_f = \Sigma K_1\,V_1^2/2g = \Sigma K_2\,V_2^2/2g$$

From the continuity equation, $Q = AV$

$$\Sigma K_1\frac{Q_1^2}{2gA_1^2} = \Sigma K_2\frac{Q_2^2}{2gA_2^2}$$

Solving for Q_1/Q_2,

$$\frac{Q_1}{Q_2} = \frac{A_1}{A_2}\sqrt{\frac{\Sigma K_2}{\Sigma K_1}} = \left(\frac{D_1}{D_2}\right)^2\sqrt{\frac{\Sigma K_2}{\Sigma K_1}} = \left(\frac{D_1}{D_2}\right)^2\sqrt{\frac{2.0 + 580.4\,f_2}{2.0 + 1{,}144\,f_1}}$$

For first trial assume flow is completely turbulent,

$$\frac{Q_1}{Q_2} = \left(\frac{0.08742}{0.1723}\right)^2\sqrt{\frac{2.0 + 580.4\times0.01899}{2.0 + 1{,}144\times0.02249}}$$

$$\frac{Q_1}{Q_2} = 0.1764 \qquad Q = Q_1 + Q_2 = 0.1764\,Q_2 + Q_2$$

$$0.5000 = 1.1764\,Q_2 \qquad Q_2 = 0.4250$$

$$Q_1 = 0.5000 - 0.4250 = 0.0750$$

for the second trial use first-trial values,

$$V_1 = Q_1/A_1 = 0.0750/(\pi/4)(0.08742)^2 = 12.50$$
$$V_2 = Q_2/A_2 = 0.4250/(\pi/4)(0.1723)^2 = 18.23$$
$$\mathbf{R}_1 = \rho_1 V_1 D_1/\mu_1 = (1.705)(12.50)(0.08742)/(13.62\times10^{-6})$$
$$\mathbf{R}_1 = 136{,}800 > 4{,}000 \therefore \text{ flow is turbulent}$$
$$\mathbf{R}_2 = \rho_2 V_2 D_2/\mu_2 = (1.705)(18.23)(0.1723)/(13.62\times10^{-6})$$
$$\mathbf{R}_2 = 393{,}200 > 4{,}000 \therefore \text{ flow is turbulent}$$

Using the Colebrook equation and Fig. 3.3.24,

$$\frac{1}{\sqrt{f_1}} = -2\log_{10}\left(\frac{1.716\times10^{-3}}{3.7} + \frac{2.51}{136{,}800\sqrt{0.024}}\right)$$

$$f_1 = 0.02389$$

$$\frac{1}{\sqrt{f_2}} = -2\log_{10}\left(\frac{8.706\times10^{-4}}{3.7} + \frac{2.51}{393{,}200\sqrt{0.020}}\right)$$

$$f_2 = 0.01981$$

$$h_f = \Sigma K_1\frac{V_1^2}{2g} = \Sigma K_2\frac{V_2^2}{2g}$$

$$\Sigma K_1 V_1^2/2g = (2.0 + 1{,}144\times0.02389)(12.50)^2/(2\times32.17) = 71.23$$
$$\Sigma K_2 V_2^2/2g = (2.0 + 580.4\times0.01981)(18.23)^2/(2\times32.17) = 69.80$$

71.23 = 69.80; further trials not justifiable because of accuracy of f, K, L/D. Use average or 70.52, so that $\Delta p = \rho g h_f = (1.705\times32.17\times70.52)/144 = 26.86$ lbf/in^2 $= p_1 - p_2 = 100 - p_2$, $p_2 = 100 - 26.86 = 73.40$ lbf/in^2 (5.061×10^5 N/m^2).

Branch Flow Problems of a single line feeding several points may be solved as shown in the following example.

EXAMPLE. Ethyl alcohol at 68°F (20°C) flows from tank A, which is maintained at a constant pressure of 100 lb/in^2 through 200 ft of 2-in cast-iron schedule 40 pipe to a Y branch connection ($K = 0.5$) where 100 ft of 2-in pipe goes to tank B, which is maintained at 80 lbf/in^2 and 50 ft of 2-in pipe to tank C, which is also maintained at 80 lbf/in^2. All tank connections are flush and sharp-edged and are at the same elevation. Estimate the flow rate to each tank.

$$D = 2.067/12 = 0.1723 \text{ ft}$$
$$\varepsilon/D = 850\times10^{-6}/0.1723 = 4.933\times10^{-3}$$

For turbulent flow, $\dfrac{1}{\sqrt{f}} = -2\log_{10}\left(\dfrac{\varepsilon/D}{3.7}\right)$

$$\frac{1}{\sqrt{f}} = -2\log_{10}\left(\frac{4.933\times10^{-3}}{3.7}\right) \qquad f = 0.03025$$

$$h_{AfB} = (p_A - p_B)/\rho g = 144(100 - 80)/(1.532\times32.17) = 58.44$$
$$h_{Afc} = (p_A - p_C)/\rho g = h_{AfB} = 58.44$$

Let point X be just before the Y; then

1. *From tank A to Y*	K
Entrance loss, sharp-edged	$= 0.5$
200 ft straight pipe $= f_{AX}$(200/0.1723)	$= 1{,}161\,f_{AX}$
	$\Sigma K_{AX} = 0.5 + 1{,}161\,f_{AX}$

2. *From Y to tank B*	
Y branch	$= 0.5$
100 ft straight pipe $= f_{XB}$(100/0.1723)	$= 580.4\,f_{XB}$
Exit loss	$= 1.0$
	$\Sigma K_{XB} = 1.5 + 580.4\,f_{XB}$

3. *From Y to tank C*	
Y branch	$= 0.5$
50 ft straight pipe $= f_{XC}$(50/0.1723)	$= 290.2\,f_{XC}$
Exit loss	$= 1.0$
	$\Sigma K_{XC} = 1.5 + 290.2\,f_{XC}$

Balance of flows:

$$Q_{AX} = Q_{XB} + Q_{XC}$$

and from continuity, ($A_{AX} = A_{XB} = A_{XC}$), $V_{AX} = V_{XB} + V_{Xc}$; then

$$h_{AfB} = \Sigma K_{AX}\frac{V_{AX}^2}{2g} + \Sigma K_{XB}\frac{V_{XB}^2}{2g}$$

$$h_{AfC} = \Sigma K_{AX}\frac{V_{AX}^2}{2g} + \Sigma K_{XC}\frac{V_{XC}^2}{2g}$$

For first trial assume completely turbulent flow

$$h_{AfB} = \frac{(0.5 + 1{,}161\,f_{AX})V_{AX}^2}{2g} + \frac{(1.5 + 580.4\,f_{XB})V_{XB}^2}{2g}$$

$$58.44 = \frac{(0.5 + 1{,}161\times0.03025)V_{AX}^2}{2\times32.17} + \frac{(1.5 + 580.4\times0.03025)V_{XB}^2}{2\times32.17}$$

$$58.44 = 0.5536\,V_{AX}^2 + 0.2962\,V_{XB}^2$$

and in a like manner

$$h_{AfC} = 58.44 = 05536\,V_{XC}^2 + 0.1598\,V_{XC}^2$$

Equating $h_{AfB} = h_{AfC}$,

$$0.5536\,V_{AX}^2 + 0.2962\,V_{XB}^2 = 0.5536\,V_{AX}^2 + 0.1598\,V_{XC}^2$$

or $\quad V_{XC} = 1.3615\,V_{XB}$ $\quad$ and since $\quad V_{AX} = V_{XB} + V_{XC}$

$$V_{AX} = V_{XB} + 1.3615\,V_{XB} = 2.3615\,V_{XB}$$

so that $\quad h_{AfB} = 58.44 = 0.5536(2.3615\,V_{XB}^2) + 0.2962\,V_{XB}^2$

$$V_{XB} = 4.156$$
$$V_{XC} = 1.3615(4.156) = 5.658$$
$$V_{AX} = 4.156 + 5.658 = 9.814$$

Second trial,

$$\mathbf{R}_{AX} = \frac{\rho V_{AX} D}{\mu} = \frac{1.532\times9.814\times0.1723}{25.06\times10^{-6}}$$

$$\mathbf{R}_{AX} = 103{,}400 > 4{,}000 \therefore \text{ flow is turbulent}$$

In a like manner,

$$\mathbf{R}_{XB} = 43{,}780 \qquad \mathbf{R}_{XC} = 59{,}600$$

Using the Colebrook equation and Fig. 3.3.24,

$$\frac{1}{\sqrt{f_{AX}}} = -2\log_{10}\left(\frac{4.933\times10^{-3}}{3.7} + \frac{2.51}{103{,}400\sqrt{0.031}}\right)$$

$$f_{AX} = 0.03116$$

In a like manner,

$$f_{XB} = 0.03231 \qquad f_{XC} = 0.03179$$

$$h_{AfB} = \frac{(0.5 + 1{,}161 \times 0.03116)V_{AX}^2}{2 \times 32.17} + \frac{(1.5 + 580.4 \times 0.03231)V_{XB}^2}{2 \times 32.17}$$

$$h_{AfB} = 0.5700\,V_{AX}^2 + 0.3148\,V_{XB}^2$$

$$h_{AfC} = 0.5700\,V_{AX}^2 + \frac{(1.5 + 290.2 \times 0.03179)V_{XC}^2}{2 \times 32.17}$$

$$h_{AfC} + 0.5700\,V_{AX}^2 + 0.1667\,V_{XC}^2$$

$$0.3148\,V_{XB}^2 = 0.1667\,V_{XC}^2$$

$$V_{XC} = 1.374\,V_{XB}$$

$$V_{AX} = V_{XB} + 1.374\,V_{XB} = 2.374\,V_{XB}$$

so that

$$h_{AfB} = 58.44 = 0.5700\,(2.374\,V_{XB})^2 + 0.3148\,V_{XB}^2$$

$$V_{XB} = 4.070 \qquad V_{XC} = 5.592 \qquad V_{AX} = 9.663$$

Further trials are not justified.

$$A = \pi D^2/4 = (\pi/4)(0.1723)^2 = 0.02332\ \text{ft}^2$$

$$Q_{AB} = V_{AB}A = 4.070 \times 0.02332 = 0.09491\ \text{ft}^3\text{/s}\ (2.686 \times 10^{-1}\ \text{m}^3\text{/s})$$

$$Q_{XC} = V_{XC}A = 5.592 \times 0.02332 = 0.1304\ \text{ft}^3\text{/s}\ (3.693 \times 10^{-3}\ \text{m}^3\text{/s})$$

Siphons are arrangements of hose or pipe which cause liquids to flow from one level A in Fig. 3.3.25 to a lower level C over an intermediate summit B. Performance of siphons may be evaluated from the equation of motion between points A and B:

$$\frac{p_A}{\gamma} + \frac{V_A^2}{2g} + z_A = \frac{p_B}{\gamma} + \frac{V_B^2}{2g} + z_B + h_{AfB}$$

Noting that on the surface $V_A = 0$ and the minimum pressure that can exist at point B is the vapor pressure pv, the maximum elevation of point B is

$$z_B - z_A = \frac{p_A}{\gamma} - \left(\frac{p_v}{\gamma} + \frac{V_B^2}{2g} + h_{AfB}\right)$$

The friction loss $h_f = \Sigma K_{AB}V_B^2/2g$, and let $V_B = V$; then

$$z_B - z_A = \frac{p_A - p_V}{\rho g} - (1 - \Sigma K_{AB})\frac{V^2}{2g}$$

Flow under this maximum condition will be uncertain. The air pump or ejector used for priming the pipe (flow will not take place unless the siphon is full of water) might have to be operated occasionally to remove accumulated air and vapor. Values of $z_B - z_A$ less than those calculated by the above equation should be used.

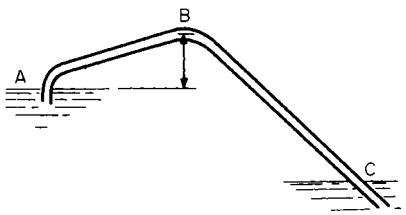

Fig. 3.3.25 Siphon.

EXAMPLE. The siphon shown in Fig. 3.3.25 is composed of 2,000 ft of 6-in schedule 40 cast-iron pipe. Reservoir A is at elevation 800 ft and C at 600 ft. Estimate the maximum height for $z_B - z_A$ if the water temperature may reach 104°F (40°C), and the amount of straight pipe from A to B is 100 ft. For the first bend $L/D = 25$ and the second (at B) $L/D = 50$. Atmospheric pressure is 14.70 lbf/in^2. For 6-in schedule 40 pipe $D = 6.065/12 = 0.5054$ ft, $\varepsilon/D = 850 \times 10^{-6}/0.5054 = 1.682 \times 10^{-3}$. Turbulent friction factor

$$1/\sqrt{f} = -2\log_{10}\left(\frac{\varepsilon D}{3.7}\right) = -2\log_{10}(1.682 \times 10^{-3}/3.7) = 0.02238$$

1. *Components from* A *to* B. (Note loss in second bend takes place in downstream piping.)

	K
Entrance (inward projection)	= 1.0
100 ft straight pipe f (100/0.5054)	= 197.9f
First bend	= 25 f
	ΣK_{AB} = 1.0 + 227.9 f

2. *Components from* A *to* C

ΣK_{AB}	= 1.0 + 2,229 f
1,900 ft of straight pipe f (1,900/0.5054)	= 3,759.4 f
Second bend	= 50 f
Exit loss	= 1
	ΣK_{AC} = 2.0 + 4,032 f

First trial assume complete turbulence. Writing the equation of motion between A and C.

$$\frac{p_A}{\gamma} + \frac{V_A^2}{2g} + z_A = \frac{p_C}{\gamma} + \frac{V_C^2}{2g} + z_C + \Sigma K_{AC}\frac{V^2}{2g}$$

Noting $V_A = V_C = 0$, and $p_A = p_C = 14.7$ lbf/in^2,

$$V = \sqrt{\frac{2g(z_A - z_C)}{\Sigma K_{AC}}} = \sqrt{\frac{2g(z_A - z_C)}{2.0 + 4{,}032f}}$$

$$= \sqrt{\frac{2 \times 32.17\,(800 - 600)}{2.0 + 4.032\,f}}$$

$$= \frac{113.44}{\sqrt{2.0 + 4{,}032 \times 0.02238}}$$

$$= 11.81$$

Second trial, use first-trial values,

$$\mathbf{R} = \frac{\rho VD}{\mu} = (1.925)(11.81)(0.5054)/(13.61 \times 10^{-6})$$

$$\mathbf{R} = 846{,}200 > 4{,}000 \therefore \text{flow is turbulent}$$

From Fig. 3.3.24 and the Colebrook equation,

$$\frac{1}{\sqrt{f}} = -2\log_{10}\left(\frac{1.682 \times 10^{-3}}{3.7} + \frac{2.51}{844{,}200\sqrt{0.023}}\right)$$

$$f = 0.02263$$

$$V = \frac{113.44}{\sqrt{2.0 + 4{,}032 \times 0.02263}} = 11.75 \qquad \text{(close check)}$$

From Sec. 4.2 steam tables at 104°F, $p_v = 1.070$ lbf/in^2, the maximum height

$$z_B - z_A = \frac{p_A - p_v}{\rho g} - (1 + \Sigma K_{AB})\frac{V^2}{2g}$$

$$= \frac{144(14.70 - 1.070)}{1.925 \times 32.17} - (1 + 1 + 227.9 \times 0.02262)\frac{(11.75)^2}{2 \times 32.17} = 16.58\ \text{ft}\ (5.053\,\text{m})$$

Note that if a ±10 percent error exists in calculation of pressure loss, maximum height should be limited to ~ 15 ft (5 m).

ASME PIPELINE FLOWMETERS

Parameters Dimensional analysis of the flow of an incompressible fluid flowing in a pipe of diameter D, surface roughness ε, through a primary element (venturi, nozzle or orifice) whose diameter is d with a velocity of V, producing a pressure drop of Δp; sensed by pressure taps located a distance L apart results in $f(\mathbf{C}_p, \mathbf{R}_d, \varepsilon/D, d/D) = 0$, which may be written as $\Delta p = \mathbf{C}_p\rho V^2/2$. Conventional practice is to express the relations as $V = \mathbf{K}\sqrt{2\Delta p/\rho}$, where $\mathbf{K}$ is the **flow coefficient,** $\mathbf{K} = 1\sqrt{\mathbf{C}_p}$, and $\mathbf{K} = f(\mathbf{R}_d, L/D, \varepsilon/d, d/D)$. The ratio of the diameter of the primary element to meter tube (pipe) diameter D is known as the **beta ratio,** where $\beta = d/D$. Application of the continuity equation leads to $Q = \mathbf{K}A_2\sqrt{2\Delta p/\rho}$, where A_2 is the area of the primary element.

Conventional practice is to base flowmeter computations on the assumption of one-dimensional frictionless flow of an incompressible fluid in a horizontal meter tube and to correct for actual conditions by the use of a coefficient for viscous effects and a factor for elastic effects.

Application of the Bernoulli equation for horizontal flow from section 1 (inlet tap) to section 2 (outlet tap) results in $p_1/\rho g + V_1^2/2g = p_2/\rho g + V_2^2/2g$ or $(p_1 - p_2)/\rho = V_2^2 - V_1^2 = \Delta p/\rho$. From the equation of continuity, $Q_i = A_1V_1 = A_2V_2$, where Q_i is the **ideal flow rate.** Substituting, $2\Delta p/\rho = Q_i^2/A_1^2 - Q_i^2/A_2^2$, and solving for Q_i, $Q_i = A_2\sqrt{2\Delta p/\rho}/\sqrt{1 - (A_2/A_1)^2}$, noting that $A_2/A_1 = (d/D)^2 = \beta^2$, $Q_i = A_2\sqrt{2\Delta p/\rho}/\sqrt{1 - \beta^4}$. The **discharge coefficient** C is defined as the ratio of the actual flow Q to the ideal flow Q_i, or $C = Q/Q_i$, so that $Q = CQ_i = CA_2\sqrt{2\Delta p/\rho}/\sqrt{1 - \beta^4}$. It is customary to write the volumetric-flow equation as $Q = CEA_2\sqrt{2\Delta p/\rho}$, where $E = 1/\sqrt{1 - \beta^4}$. E is called the **velocity-of-approach factor** because it accounts for the one-dimensional kinetic energy at the upstream tap. Comparing the equation from dimensional analysis with the modified Bernoulli equation, $Q = \mathbf{K}A_2\sqrt{2\Delta p/\rho} = CEA_2\sqrt{2\Delta p/\rho}$, or $\mathbf{K} = CE$ and $C = f(\mathbf{R}_d, L/D, \beta)$.

For compressible fluids, the incompressible equation is modified by the **expansion factor** Y, where Y is defined as the ratio of the flow of a compressible fluid to that of an incompressible fluid at the same value of Reynolds number. Calculations are then based on inlet-tap-fluid properties, and the compressible equation becomes

$$Q_1 = \mathbf{K}YA_2\sqrt{2\Delta p/\rho_1} = CEYA_2\sqrt{2\Delta p/\rho_1}$$

where $Y = f(L/D, \varepsilon/D, \beta, \mathbf{M})$. Reynolds number $\boldsymbol{R}_d$ is also based on inlet-fluid properties, but on the primary-element diameter or

$$\mathbf{R}_d = \rho_1V_2d/\mu_1 = \rho_1(Q_1/A_2)d/\mu_1 = 4\rho_1Q_1/\pi\, d\mu_1$$

Caution The numerical values of coefficients for flowmeters given in the paragraphs to follow are based on experimental data obtained with long, straight pipes where the velocity profile approaching the primary element was fully developed. The presence of valves, bends, and fittings upstream of the primary element can cause serious errors. For approach and discharge, straight-pipe requirements, "Fluid Meters," (6th ed., ASME, 1971) should be consulted.

Venturi Tubes Figure 3.3.26 shows a typical venturi tube consisting of a cylindrical inlet, convergent cone, throat, and divergent cone. The convergent entrance has an included angle of about 21° and the divergent cone 7 to 8°. The purpose of the divergent cone is to reduce the overall pressure loss of the meter; its removal will have no effect on the coefficient of discharge. Pressure is sensed through a series of holes in the inlet and throat. These holes lead to an annular chamber, and the two chambers are connected to a pressure-differential sensor. Discharge coefficients for venturi tubes as established by the American Society of Mechanical Engineers are given in Table 3.3.12. Coefficients of discharge outside the tabulated limits must be determined by individual calibrations.

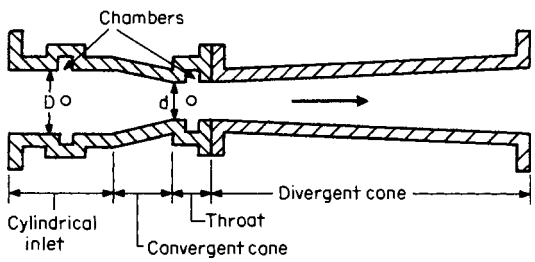

Fig. 3.3.26 Venturi tube.

EXAMPLE. Benzene at 68°F (20°C) flows through a machined-inlet venturi tube whose inlet diameter is 8 in and whose throat diameter is 3.5 in. The differential pressure is sensed by a U-tube manometer. The manometer contains mercury under the benzene, and the level of the mercury in the throat leg is 4 in. Compute the volumetric flow rate. Noting that $D = 8$ in (0.6667 ft) and $\beta = 3.5/8 = 0.4375$ are within the limits of Table 3.3.12, assume $C = 0.995$, and then check $\mathbf{R}_d$ to verify if it is within limits. For a U-tube manometer (Fig. 3.3.6*a*), $p_2 - p_1 = (\gamma_m - \gamma_f)h = \Delta p$ and $\Delta p/\rho_1 = (\rho_m g - \rho_f g)h/\rho_f = g(\rho_m/\rho_f - 1)h = 32.17(26.283/1.705 - 1)(4/12) = 154.6$. For a liquid, $Y = 1$ (incompressible fluid), $E = 1/\sqrt{1 - \beta^4} = 1/\sqrt{1 - (0.4375)^4} = 1.019$.

$$Q_1 = CEY A_d\sqrt{2\Delta p/\rho_1}$$
$$= (0.995)(1.019)(\pi/4)(3.5/12)^2\sqrt{2 \times 154.6}$$
$$= 1.192\ \text{ft}^3/\text{s}\ (3.373 \times 10^{-3}\ \text{m}^3/\text{s})$$

$\mathbf{R}_d = 4\rho_1Q_1/\pi\, d\mu_1 = 4(1.705)(1.192)/\pi(3.5/12)(13.62 \times 10^{-6})$
$\mathbf{R}_d = 651{,}400$, which lies between 200,000 and 1,000,000 of Table 3.3.12 $\therefore$ solution is valid

Flow Nozzles Figure 3.3.27 shows an ASME flow nozzle. This nozzle is built to rigid specifications, and pressure differential may be sensed by either throat taps or pipe-wall taps. Taps are located one pipe diameter upstream and one-half diameter downstream from the nozzle inlet. Discharge coefficients for ASME flow nozzles may be computed from $C = 0.9975 - 0.00653\ (10^6/\mathbf{R}_d)^a$, where $a = 1/2$ for $\mathbf{R}_d < 10^6$ and $a = 1/5$ for $\mathbf{R}_d > 10^6$. Most of the data were obtained for D between 2 and 15.75 in, $\mathbf{R}_d$ between 10^4 and 10^6, and beta between 0.15 and 0.75. For values of C within these ranges, a tolerance of 2 percent may be anticipated, and outside these limits, the tolerance may be greater than 2 percent. Because slight variations in form or dimension of either pipe or nozzle may affect the observed pressures, and thus cause the exponent a and the slope term (-0.00653) to vary considerably, nozzles should be individually calibrated.

EXAMPLE. An ASME flow nozzle is to be designed to measure the flow of 400 gal/min of 68°F (20°C) water in a 6-in schedule 40 (inside diameter = 6.065 in) steel pipe. The pressure differential across the nozzle is not to exceed 75 in of water. What should be the throat diameter of the nozzle? $\Delta p = h\rho_1 g$, $\Delta p/\rho_1 = hg = (75/12)(32.17) = 201.1$, $Q = (400/60)(231/1{,}728) = 0.8912\ \text{ft}^3/\text{s}$. A trial-and-error solution is necessary to establish the values of C and E because they are dependent upon β and $\mathbf{R}_d$, both of which require that d be known. Since $\mathbf{K} = CE \approx 1$, assume for first trial that $CE = 1$. Since a liquid is involved, $Y = 1$, $A_2 = Q_1/(CE)(Y)\sqrt{2\Delta p/\rho_1} = (0.8912)/(1)(1)\sqrt{2 \times 201.1} = 0.04444\ \text{ft}^2$, $d = \sqrt{4A_2/\pi} = \sqrt{4(0.04444)/\pi} = 0.2379$ ft or $d = 0.2379 \times 12 = 2.854$ in, $\beta = d/D = 2.854/6.065 = 0.4706$.

For second trial use first-trial value:

$$E = 1/\sqrt{1 - \beta^4} = 1/\sqrt{1 - (0.4706)^4} = 1.025$$

$\mathbf{R}_d = 4\rho_1Q_1/\pi d\mu_1 = 4(1.937)(0.8912)/\pi(0.2379)(20.92 \times 10^{-6}) = 442{,}600 < 10^6 \therefore a = 1/2$ and $C = 0.9975 - 0.00653(10^6/\mathbf{R}_d)^{1/2}$. $C = 0.9975 - 0.00653(10^6/442{,}600)^{1/2} = 0.9877$. $A_2 = (0.8912)/(0.9877 \times 1.025)\sqrt{2 \times 201.1} = 0.04389$, $d_2 = \sqrt{4 \times (0.04389/\pi)} = 0.2364$, $d_2 = 0.2364 \times 12 = 2.837$ in $(7.205 \times 10^{-2}$ m). Further trials are not necessary in view of the ± 2 percent tolerance of C.

Table 3.3.12 ASME Coefficients for Venturi Tubes

Type of inlet cone	Reynolds number $\mathbf{R}_d$		Inlet diam D in $(2.54 \times 10^{-2}$ m)		β		C	Tolerance, %
	Min	Max	Min	Max	Min	Max		
Machined	5×10^5	1×10^6	2	10	0.4	0.75	0.995	±1.0
Rough welded sheet metal		2×10^6	8	48		0.70	0.985	±1.5
Rough cast			4	32	0.3	0.75	0.984	±0.7

SOURCE: Compiled from data given in "Fluid Meters," 6th ed., ASME, 1971.

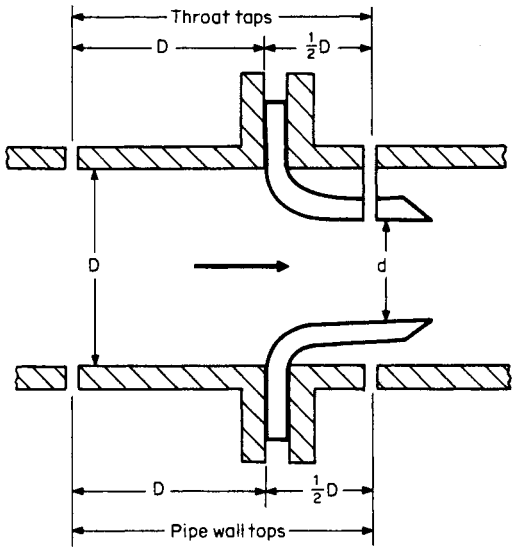

Fig. 3.3.27 ASME flow nozzle.

Compressible Flow—Venturi Tubes and Flow Nozzles The expansion factor Y is computed based on the assumption of a frictionless adiabatic (isentropic) expansion of an ideal gas from the inlet to the throat of the primary element, resulting in (see Sec. 4.1)

$$Y = \left[\frac{kr^{2/k}(1 - r^{(k-1)/k})(1 - \beta^4)}{(1 - r)(k - 1)(1 - \beta^4 r^{2/k})}\right]^{1/2}$$

where $r = p_2/p_1$.

Maximum flow is obtained when the critical pressure ratio is reached. The critical pressure ratio r_c may be calculated from

$$r^{(1-k)/k} + \frac{k - 1}{2}\beta^4 r^{2/k} = \frac{k + 1}{2}$$

Table 3.3.13 gives selected values of Y_c and r_c.

EXAMPLE. A piping system consists of a compressor, a horizontal straight length of 2-in-inside-diameter pipe, and a 1-in-throat-diameter ASME flow nozzle attached to the end of the pipe, discharging into the atmosphere. The compressor is operated to maintain a flow of air with 115 lbf/in^2 and 140°F (60°C) conditions in the pipe just one pipe diameter before the nozzle inlet. Barometric pressure is 14.7 lbf/in^2. Estimate the flow rate of the air in lbm/s.

From the equation of state, $\rho_1 = p_1/g_c RT_1 = (144 \times 115)/(32.17)(53.34)(140 + 459.7) = 0.01609$ slug/ft^3, $\beta = d/D = 1/2 = 0.5$, $E = 1/\sqrt{1 - \beta^4} = 1/\sqrt{1 - (0.5)^4} = 1.033$, $r = p_2/p_1 = 14.7/115 = 0.1278$, but from Table 3.3.13 at $\beta = 0.5$, $k = 1.4$, $r_c = 0.5362$, and $Y_c = 0.6973$, so that because of critical flow the throat pressure $p_c = 115 \times 0.5362 = 61.66$ lbf/in^2. $\Delta p_c/\rho_1 = 144(115 - 61.66)/0.01609 = 477{,}375$. A trial-and-error solution is necessary to obtain C. For the first trial assume $10^6/\mathbf{R}_d = 0$ or $C = 0.9975$. Then $Q_1 = CEY_c A_2\sqrt{2\Delta p_c/\rho_1} = (0.9975)(1.033)(0.6973)(\pi/4)(1.12)^2\sqrt{2 \times 477{,}375} = 3.829$ ft^3/s, $\mathbf{R}_d = 4\rho_1 Q/\pi d\mu_1 = (4)(0.01609)(3.828)/\pi(1/12)(41.79 \times 10^{-8}) = 2{,}252{,}000$.

Second trial, use first-trial values:

$$\mathbf{R} > 10^6,\ a = 115,\ C = 0.9975 - (0.00653)(16^6/2{,}252{,}000)^{1/5}$$
$$C = 0.9919,\ Q_1 = 3.828(0.9919/0.9975) = 3.806\ \text{ft}^3/\text{s}$$

Further trials are not necessary in view of ±2 percent tolerance on C.

$$\dot{m} = Q_1\rho_1 g = 3.806 \times 0.01609 \times 32.17 = 1.970\ \text{lbm/s}\ (0.8935\ \text{kg/s})$$

Orifice Meters When a fluid flows through a square-edged thin-plate orifice, the minimum-flow area is found to occur downstream from the orifice plate. This minimum area is called the vena contracta, and its location is a function of beta ratio. Figure 3.3.28 shows the relative pressure difference due to the presence of the orifice plate. Because the location of the pressure taps is vital, it is necessary to specify the exact position of the downstream pressure tap. The jet contraction

Table 3.3.13 Expansion Factors and Critical Pressure Ratios for Venturi Tubes and Flow Nozzles

		Critical values		Expansion factor Y

SOURCE: Murdock, "Fluid Mechanics and Its Applications," Houghton Mifflin, 1976.

amounts to about 60 percent of the orifice area; so orifice coefficients are in the order of 0.6 compared with the nearly unity obtained with venturi tubes and flow nozzles.

Three pressure-differential-measuring tap locations are specified by the ASME. These are the flange, vena contracta, and the 1 D and 1/2 D. In the flange tap, the location is always 1 in from either face of the orifice plate regardless of the size of the pipe. In the vena contracta tap, the upstream tap is located one pipe diameter from the inlet face of the orifice plate and the downstream tap at the location of the vena contracta. In the 1 D and 1/2 D tap, the upstream tap is located one pipe diameter from the inlet face of the orifice plate and downstream one-half pipe diameter from the inlet face of the orifice plate.

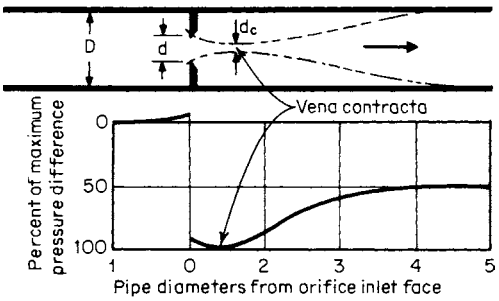

Fig. 3.3.28 Relative-pressure changes due to flow through an orifice.

Flange taps are used because they can be prefabricated, and flanges with holes drilled at the correct locations may be purchased as off-the-shelf items, thus saving the cost of field fabrication. The disadvantage of flange taps is that they are not symmetrical with respect to pipe size. Because of this, coefficients of discharge for flange taps vary greatly with pipe size.

Vena contracta taps are used because they give the maximum differential for any given flow. The disadvantage of the vena contracta tap is that if the orifice size is changed, a new downstream tap must be drilled. The 1 D and 1/2 D taps incorporate the best features of the vena contracta taps and are symmetrical with respect to pipe size.

Discharge coefficients for orifices may be calculated from

$$C = C_o + \Delta C \mathbf{R}_d^{-0.75} \qquad (\mathbf{R}_d > 10^4)$$

where C_o and ΔC are obtained from Table 3.3.14.

Tolerances for uncalibrated orifice meters are in the order of ±1 to ±2 percent depending upon β, D, and $\boldsymbol{R}_d$.

Compressible Flow through ASME Orifices As shown in Fig. 3.3.28, the minimum flow area for an orifice is at the vena contracta located downstream of the orifice. The stream of compressible fluid is not restrained as it leaves the orifice throat and is free to expand transversely and longitudinally to the point of minimum-flow area. Thus the contraction of the jet will be less for a compressible fluid than for a liquid. Because of this, the theoretical-expansion-factor equation may not be used with orifices. Neither may the critical-pressure-ratio equation be used, as the phenomenon of critical flow has not been observed during testing of orifice meters.

For orifice meters, the following equation, which is based on experimental data, is used:

$$Y = 1 - (0.41 + 0.35\beta^4)(\Delta p/p_1)/k$$

EXAMPLE. Air at 68°F (20°C) and 150 lbf/in^2 flows in a 2-in schedule 40 pipe (inside diameter = 2.067 in) at a volumetric rate of 15 ft^3/min. A 0.5500-in ASME orifice equipped with flange taps is used to meter this flow. What deflection in inches could be expected on a U-tube manometer filled with 60°F water? From the equation of state, $\rho_1 = p_1/g_c RT_1 = (144 \times 150)/(32.17)(53.34)(68 + 459.7) = 0.02385$ slug/ft^3, $\beta = 0.5500/2.067 = 0.2661$. $Q_1 = 15/60 = 0.25$ ft^3/s, $A_2 = (\pi/4)(0.5500/12)^2 = 1.650 \times 10^{-3}$ ft^2. $E = 1/\sqrt{1 - \beta^4} = 1/\sqrt{1 - (0.2661)^4} = 1.003$. $\mathbf{R}_d = 4\rho_1 Q_1/\pi\, d\mu_1 = 4(0.02385)(0.25)/\pi(0.5500/12)(39.16 \times 10^{-8})$. $\mathbf{R}_d = 423{,}000$.

From Table 3.3.14 at $\beta = 0.2661$, $D = 2.067$-in flange taps, by interpolation, $C_o = 0.5977$, $\Delta C = 9.087$, from orifice-coefficient equation $C = C_o + \Delta C \mathbf{R}_d^{-0.75}$. $C = 0.5977 + (9.087)(423{,}000)^{-0.75} = 0.5982$. A trial-and-error solution is required because the pressure loss is needed in order to compute Y. For the first trial, assume $Y = 1$, $\Delta p = (Q_1/CEYA_2)^2(\rho_1/2) = [(0.25)/(0.5982)(1.003)(Y)(1.650 \times 10^{-3})]^2(0.02385/2) = 760.5/Y^2 = 760.5/(1)^2 = 760.5$ lbf/ft^2.

SOURCE: Compiled from data given in ASME Standard MFC-3M-1984 "Measurement of Fluid Flow in Pipes. Using Orifice, Nozzle and Venturi."

For the second trial we use first-trial values.

$$Y = 1 - (0.41 + 0.35\,\beta^4)\frac{\Delta p/p_1}{k}$$

$$= 1 - [0.41 + 0.35(0.2661)^4]\frac{760.5/144 \times 150}{1.4} = 0.9896$$

$$\Delta p = \frac{760.5}{Y^2} = \frac{760.5}{(0.9896)^2} = 776.1 \text{ lbf/ft}^2$$

For the third trial we use second-trial values.

$$Y = 1 - [0.41 + 0.35(0.2661)^4]\frac{776.1/144 \times 150}{1.4} = 0.9894$$

$$\Delta p = \frac{776.1}{(0.9894)^2} = 793.3 \text{ lbf/ft}^2$$

Resubstitution does not produce any further change in Y. From the U-tube-manometer equation:

$$h = \frac{\Delta p}{\gamma_m - \gamma_f} = \frac{\Delta p}{g_c(\rho_m - \rho_f)}$$

$$= \frac{793.3}{32.17}(1.937 - 0.02385) = 12.89 \text{ ft}$$

$$= 12.89 \times 12 = 154.7 \text{ in (3.929 m)}$$

PITOT TUBES

Definition A Pitot tube is a device that is shaped in such a manner that it senses stagnation pressure. The name "Pitot tube" has been applied to two general classifications of instruments, the first being a tube that measures the impact or stagnation pressures only, and the second a combined tube that measures both impact and static pressures with a single primary instrument. The combined sensor is called a Pitot-static tube.

Tube Coefficient From Fig. 3.3.29, it is evident that the Pitot tube can sense only the stagnation pressure resulting from the local stream-tube velocity U. The local ideal velocity U_i for an incompressible fluid is obtained by the application of the Bernoulli equation ($z_S = z$), $U_i^2/2g + p/\rho g = U_S^2/2g + p_S/\rho g$. Solving for U_i and noting that by definition

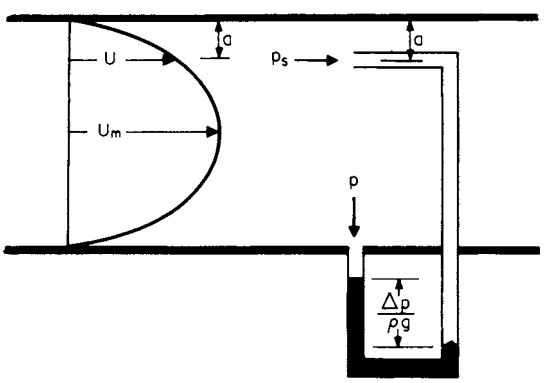

Fig. 3.3.29 Notation for Pitot tube study.

$U_S = 0$, $U_i = \sqrt{2(p_S - p)/\rho}$. Conventional practice is to define the **tube coefficient** C_T as the ratio of the actual stream-tube velocity to the ideal stream-tube velocity, or $C_T = U/U_i$ and $U = C_T U_i = C_T\sqrt{2\Delta p/\rho}$. The numerical value of C_T depends primarily upon its geometry. The value of C_T may be established (1) by calibration with a uniform velocity, (2) from published data for similar geometry, or (3) in the absence of other information, may be assumed to be unity.

Pipe Coefficient For the calculation of volumetric flow rate, it is necessary to integrate the continuity equation, $Q = \int U\,da = AV$. The **pipe coefficient** C_P is defined as the ratio of the average velocity to the stream-tube velocity, or $C_P = V/U$, and $Q = C_P A_1 V = C_p C_T A_1\sqrt{2\Delta p/\rho}$. The numerical value of C_P is dependent upon the location of the tube and the **velocity profile.** The values of C_P may be established by (1) making a "traverse" by taking data at various points in the flow stream and determining the velocity profile experimentally (see "Fluid Meters," 6th ed., ASME, 1971, for locations of traverse points), (2) using standard velocity profiles, (3) locating the Pitot tube at a point where $U = V$, and (4) assuming one-dimensional flow of $C_P = 1$ **only** in the absence of other data.

Compressible Flow For compressible flow, the **compression factor** Z is based on the assumption of a frictionless adiabatic (isentropic) compression of an ideal gas from the moving stream tube to the stagnation point (see Sec. 4.1), which results in

$$Z = \left[\frac{k}{k-1}\frac{(p_S/p)^{(k-1)/k} - 1}{(p_S/p) - 1}\right]^{1/2}$$

and the volumetric flow rate becomes

$$Q = C_P C_T Z A_1\sqrt{2\Delta p/\rho}$$

EXAMPLE. Carbon dioxide flows at 68°F (20°C) and 20 lbf/in² in an 8-in schedule 40 galvanized-iron pipe. A Pitot tube located on the pipe centerline indicates a pressure differential of 6.986 lbf/in². Estimate the mass flow rate. For 8-in schedule 40 pipe $D = 7.981/12 = 0.6651$, $\varepsilon/D = 500 \times 10^{-6}/0.6651 = 7.518 \times 10^{-4}$, $A_1 = \pi D^2/4 = (\pi/4)(0.6651)^2 = 0.3474$ ft², $p_S = p + \Delta p = 20 + 6.986 = 26.986$ lbf/in². From the equation of state, $\rho = p/g_c RT_o = (20 \times 144)/(32.17)(35.11)(68 + 459.7) = 0.004832$,

$$Z = \left[\frac{k}{k-1}\frac{(p_S/p)^{(k-1)/k} - 1}{(p_S/p) - 1}\right]^{1/2}$$

$$= \left\{[1.3/(1.3 - 1)] \times \frac{(26.986/20)^{(1.3-1)/1.3} - 1}{(26.986/20) - 1}\right\}^{1/2} = 0.9423$$

In the absence of other data, C_T may be assumed to be unity. A trial-and-error solution is necessary to determine C_p, since f requires flow rate. For the first trial assume complete turbulence.

$$1/\sqrt{f} = -2\log_{10}(7.518 \times 10^{-4}/3.7) \qquad \sqrt{f} = 0.1354$$

$$C_P = V/U = V/U_{\max} = 1/(1 + 1.43\sqrt{f}) = 1/(1 + 1.43 \times 0.1354) = 0.8378$$

$$V = C_P C_T Z\sqrt{2\Delta P/\rho} = (0.8378)(1)(0.9423)\sqrt{2 \times 144(6.987)/(0.004832)}$$

$$V = 509.4 \text{ ft/s}$$

$$\mathbf{R} = \rho VD/\mu = (0.004832)(509.4)(0.6651)/(30.91 \times 10^{-18})$$

$$\mathbf{R} = 5{,}296{,}000 > 4{,}000 \therefore \text{ flow is turbulent}$$

From the Colebrook equation and Fig. 3.3.24,

$$\frac{1}{\sqrt{f}} = -2\log_{10}\left(\frac{7.518 \times 10^{-4}}{3.7} + \frac{2.51}{5{,}296{,}000\sqrt{0.018}}\right)$$

$$\sqrt{f} = 0.1357$$

$$C_P = 1/(1 + 1.43 \times 0.1357) = 0.8375 \qquad \text{(close check)}$$

$$V = 509.4(0.8375/8378) = 509.2 \text{ ft/s}$$

From the continuity equation, $m = \rho A_1 V g_c = (0.004832)(0.3474)(509.2)(32.17) = 27.50$ lbm/s (12.47 kg/s).

ASME WEIRS

Definitions A weir is a dam over which liquids are forced to flow. Weirs are used to measure the flow of liquids in open channels or in conduits which do not flow full; i.e., there is a free liquid surface. Weirs are almost exclusively used for measuring water flow, although small ones have been used for metering other liquids. Weirs are classified according to their notch or opening as follows: (1) **rectangular notch** (original form); (2) V or **triangular notch;** (3) **trapezoidal notch,** which when designed with end slopes one horizontal to four vertical is called the **Cipolletti weir;** (4) the **hyperbolic weir** designed to give a constant coefficient of discharge; and (5) the **parabolic weir** designed to give a linear relationship of head to flow. As shown in Fig. 3.3.30, the top of the weir is the crest and the distance from the liquid surface to the crest h is called the **head.**

The sheet of liquid flowing over the weir crest is called the **nappe.** When the nappe falls downstream of the weir plate, it is said to be free,

or **aerated.** When the width of the approach channel L_c is greater than the crest length L_w, the nappe will contract so that it will have a minimum width less than the crest length. For this reason, the weir is known as a **contracted weir.** For the special case where $L_w = L_c$, the contractions do not take place, and such weirs are known as **suppressed weirs.**

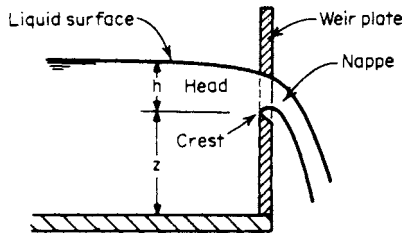

Fig. 3.3.30 Notation for weir study.

Parameters The forces acting on a liquid flowing over a weir are inertia, viscous, surface tension. and gravity. If the weir head produced by the flow is h, the characteristic length of the weir is L_w, and the channel width is L_c, either similarity or dimensional analysis leads to $f(\mathbf{F, W, R}, L_w/L_c) = 0$, which may be written as $V = K\sqrt{2gh}$, where K is the **weir coefficient** and $K = f(\mathbf{W, R}, L_w/L_c)$. Since the weir has been almost exclusively used for metering water flow over limited temperature ranges, the effects of surface tension and viscosity have not been adequately established by experiment.

Caution The numerical values of coefficients for weirs are based on experimental data obtained from calibration of weirs with long approaches of straight channels. Head measurement should be made at a distance at least three or four times the expected maximum head h. Screens and baffles should be used as necessary to ensure steady uniform flow without waves or local eddy currents. The approach channel should be relatively wide and deep.

Rectangular Weirs Figure 3.3.31 shows a rectangular weir whose crest width is L_w. The volumetric flow rate may be computed from the continuity equation: $Q = AV = (L_w h)(K\sqrt{2gh}) = KL_w\sqrt{2g}\,h^{3/2}$. The ASME "Fluid Meters" report recommends the following equation for rectangular weirs: $Q = (\frac{2}{3})CL_a\sqrt{2g}\,h_a^{3/2}$, where C is the **coefficient of discharge** $C = f(L_w/L_c, h/Z)$, L_a is the adjusted crest length $L_a = L_w + \Delta L$, and h_a is the adjusted weir head $h_a = h + 0.003$ ft. Values of C and ΔL may be obtained from Table 3.3.15. To avoid the possibility that the liquid drag along the sides of the channel will affect side contractions, $L_c - L_w$ should be at least $4h$. The minimum crest length should be 0.5 ft to prevent mutual interference of the end contractions The minimum head for free flow of the nappe should be 0.1 ft.

EXAMPLE. Water flows in a channel whose width is 40 ft. At the end of the channel is a rectangular weir whose crest width is 10 ft and whose crest height is 4 ft. The water flows over the weir at a height of 3 ft above the crest of the weir. Estimate the volumetric flow rate. $L_w/L_c = 10/40 = 0.25$, $h/Z = 3/4 = 0.75$, from Table 3.3.15 (interpolated), $C = 0.589$, $\Delta L = 0.008$, $L_a = L_w + \Delta L = 10 + 0.008 = 10.008$ ft, $h_a = h + 0.003 = 3 + 0.003 = 3.003$ ft, $Q = (2/3)CL_a\sqrt{2g}\,h^{3/2}$, $Q = (2/3)(0.589)(10.008)(2 \times 32.17)^{1/2}(3.003)^{3/2}$ $Q = 164.0$ ft^3/s (4.644 m^3/s).

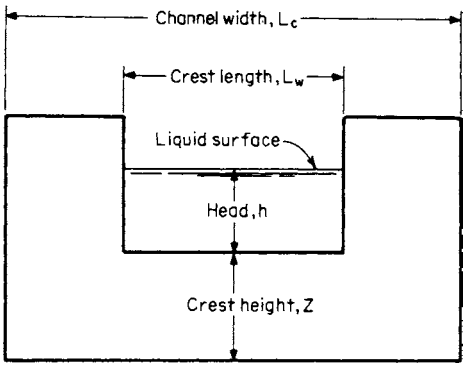

Fig. 3.3.31 Rectangular weir.

Triangular Weirs Figure 3.3.32 shows a triangular weir whose notch angle is θ. The volumetric flow rate may be computed from the continuity equation $Q = AV = (h^2 \tan\theta/2)(K\sqrt{2gh}) = K\tan(\theta/2)\sqrt{2g}\,h^{5/2}$. The ASME "Fluid Meters" report recommends the following for triangular weirs: $Q = (8/15)\,C\tan(\theta/2)\sqrt{2g}(h + \Delta h)^{5/2}$, where C is the coefficient of discharge $C = f(\theta)$ and Δh is the correction for head/crest ratio $\Delta h = f(\theta)$. Values of C and Δh may be obtained from Table 3.3.16.

EXAMPLE. It is desired to maintain a flow of 167 ft^3/s in an open channel whose width is 20 ft at a height of 7 ft by locating a triangular weir at the end of the channel. The weir has a crest height of 2 ft. What notch angle is required to maintain these conditions? A trial-and-error solution is required. For the first trial assume $\theta = 60°$ (mean value 20 to 100°): then $C = 0.576$ and $\Delta h = 0.004$.

$$h + Z = 7 = h + 2 \therefore h = 5$$
$$Q = (8/15)\,C\tan(\theta/2)\sqrt{2g}(h + \Delta h)^{5/2}$$

$167 = (8/15)(0.576)\tan(\theta/2)\sqrt{2 \times 32.17}\,(5 + 0.004)^{5/2}$, $\tan^{-1}(\theta/2) = 1.20993$, $\theta = 100°51'$.

Second trial, using $\theta = 100$, $C = 0.581$, $\Delta h = 0.003$, $167 = (8/15)(0.581)\tan(\theta/2)\sqrt{2 \times 32.17}\,(5 + 0.003)^{5/2}$, $\tan^{-1}(\theta/2) = 1.20012$, $\theta = 100°39'$ (close check).

OPEN-CHANNEL FLOW

Definitions An **open channel** is a conduit in which a liquid flows with a free surface subjected to a constant pressure. Flows of water in natural streams, artificial canals, irrigation ditches, sewers, and flumes are examples where the water surface is subjected to atmospheric pressure. The flow of any liquid in a pipe where there is a free liquid surface is an example of open-channel flow where the liquid surface will be subjected to the pressure existing in the pipe. The **slope** S of a channel is the change in elevation per unit of horizontal distance. For small slopes, this is equivalent to dividing the change in elevation by the distance L measured along the channel bottom between two sections. For steady uniform flow, the velocity distribution is the same at all sections of the channel, so that the energy grade line has the same angle as the bottom of the channel, thus:

$$S = h_f/L$$

The distance between the liquid surface and the bottom of the channel is sometimes called the **stage** and is denoted by the symbol y in Fig. 3.3.33. When the stages between the sections are not uniform, that is, $y_1 \neq y_2$ or the cross section of the channel changes, or both, the flow is said to be **varied.** When a liquid flows in a channel of uniform cross section and the slope of the surface is the same as the slope of the bottom of the channel ($y_1 = y = y_2$), the flow is said to be **uniform.**

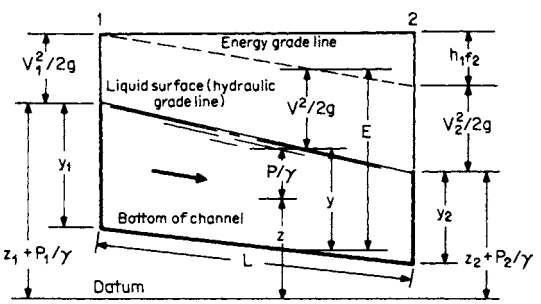

Fig. 3.3.33 Notation for open channel flow.

Parameters The forces acting on a liquid flowing in an open channel are inertia, viscous, surface tension, and gravity. If the channel has a surface roughness of ε, a hydraulic radius of R_h, and a slope of S, either similarity or dimensional analysis leads to $f(\mathbf{F, W, R,}\ \varepsilon/4R_h) = 0$, which may be written as $V = C\sqrt{R_hS}$, where $C = f(\mathbf{W, R,}\ \varepsilon/4R_h)$ and is known as the **Chézy coefficient.** The relationship between the Chézy coefficient C and the friction factor may be determined by equating

$$V = \sqrt{8R_hh_fg/fL} = C\sqrt{R_hS} = C\sqrt{(R_hh_f)/L}$$

or $C = (8g/f)^{1/2}$. Although this establishes a relationship between the Chézy coefficient and the friction factor, it should be noted that $f = f(\mathbf{R,}\ \varepsilon/4R_h)$ and $C = f(\mathbf{W, R,}\ \varepsilon/4R_h)$, because in open-channel flow, pressure forces are absent and in pipe flow, surface-tension and gravity forces are absent. For these reasons, data obtained in pipe flow should not be applied to open-channel flow.

Roughness Factors For open-channel flow, the Chézy coefficient is calculated by the Manning equation, which was developed from examination of experimental results of water tests. The **Manning relation** is stated as

$$C = \frac{1.486}{n}R_h^{1/6}$$

where n is a roughness factor and should be a function of Reynolds number, Weber number, and relative roughness. Since only water-test data obtained at ordinary temperatures support these values, it must be assumed that n is the value for turbulent flow only. Since surface tension is a weak property, the effects of Weber-number variation are negligible, leaving n to be some function of surface roughness. Design values of n are given in Table 3.3.17. Maximum flow for a given slope will take place when R_h is a maximum, and values of R_h max are given in Table 3.3.6.

Table 3.3.17 Values of Roughness Factor n for Use in Manning Equation

Surface	n	Surface	n
Brick	0.015	Earth, with stones	0.035
Cast iron	0.015	and weeds	
Concrete, finished	0.012	Gravel	0.029
Concrete, unfinished	0.015	Riveted steel	0.017
Brass pipe	0.010	Rubble	0.025
Earth	0.025	Wood, planed	0.012
		Wood, unplaned	0.013

SOURCE: Compiled from data given in R. Horton, *Engineering News,* 75, 373, 1916.

EXAMPLE. It is necessary to carry 150 ft^3/s of water in a rectangular unplaned timber flume whose width is to be twice the depth of water. What are the required dimensions for various slopes of the flume? From Table 3.3.6, $A = b^2/2$ and $R_h = h/2 = b/4$. From Table 3.3.17, $n = 0.013$ for unplaned wood. From Manning's equation, $C = 1.486/n$, $R_h^{1/6} = (1.486/0.013)(b^{1/6}/(4)^{1/6} = 90.73\,b^{1/6}$. From the continuity equation, $V = Q/A = 150/(b^2/2)$, $V = 300/b^2$. From the Chézy equation, $V = C\sqrt{R_hS} = 300/b^2 = 90.73b^{1/6}\sqrt{(b/4)S}$; solving for b, $b = 2.0308/S^{3/16}$.

Assumed S:	1×10^{-1}	1×10^{-2}	1×10^{-3}	1×10^{-4}	1×10^{-5}	1×10^{-6} ft/ft
Required b:	3.127	4.816	7.416	11.42	17.59	27.08 ft

EXAMPLE. A rubble-lined trapezoidal canal with 45° sides is to carry 360 ft^3/s of water at a depth of 4 ft. If the slope is 9×10^{-4} ft/ft, what should be the dimensions of the canal? From Table 3.3.17, $n = 0.025$ for rubble. From Table 3.3.6 for $\alpha = 45°$, $A = (b + h)h = 4(b + 4)$, and $R_h = (b + h)h/(b + 2.828h) = 4(b + 4)/(b + 11.312)$. From the Manning relation, $C = (1.486/n)(R_h^{1/6}) = (1.486/0.025)R_h^{1/6} = 59.44\,R_h^{1/6}$. For the first trial, assume $R_h = R_h$ max $= h/2 = 4/2 = 2$; then $C = 59.44(2)^{1/6} = 66.72$ and $V = C\sqrt{R_hS} = 66.72\sqrt{2 \times 9 \times 10^{-4}} = 2.831$. From the continuity equation, $A = Q/V = 360/2.831 = 127.2 = 4(b + 4)$; $b = 27.79$ ft. Second trial, use the first trial, $R_h = 4(27.79 + 4)/(27.79 + 11.312)$, $R_h = 3.252$, $V = 59.44(3.252)^{1/6}\sqrt{3.252 \times 9 \times 10^{-4}} = 3.914$. From the equation of continuity, $Q/V = 360/3.914 = 91.97 = 4(b + 4)$, $b = 18.99$. Subsequent trial-and-error solutions result in a balance at $b = 19.93$ ft (6.075 m).

Specific Energy Specific energy is defined as the energy of the fluid referred to the bottom of the channel as the datum. Thus the specific energy E at any section is given by $E = y + V^2/2g$; from the continuity equation $V = Q/A$ or $E = y + (Q/A)^2/2g$. For a rectangular channel whose width is b, $A = by$; and if $\mathbf{q}$ is defined as the flow rate per unit width, $\mathbf{q} = Q/b$ and $E = y + (\mathbf{q}b/by)^2/2g = y + (\mathbf{q}/y)^2/2g$.

Critical Values For rectangular channels, if the specific-energy equation is differentiated and set equal to zero, critical values are obtained; thus $dE/dy = d/dy[y + (\mathbf{q}/y)^2/2g] = 0 = 1 - \mathbf{q}^2/y^3g$ or $\mathbf{q}_c^2 = y_c^3 g$. Substituting in the specific-energy equation, $E = y_c + y_c^3 g/2gy_c^2 = 3/2y_c$. Figure 3.3.34 shows the relation between depth and specific energy for a constant flow rate. If the depth is greater than critical, the flow is *subcritical;* at critical depth it is *critical* and at depths below critical the flow is *supercritical.* For a given specific energy, there is a maximum unit flow rate that can exist.

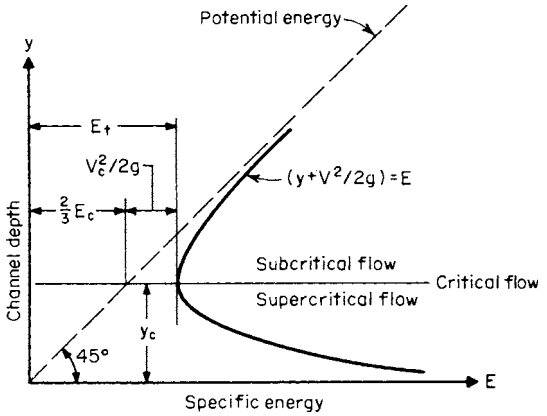

Fig. 3.3.34 Specific energy diagram, constant flow rate.

The **Froude number** $\mathbf{F} = V/\sqrt{gy}$, when substituted in the specific-energy equation, yields $E = y + (\mathbf{F}^2 gy)/2g = y(1 + \mathbf{F}^2/2)$ or $E/y = 1 + \mathbf{F}^2/2$. For critical flow, $E_c/y_c = 3/2$. Substituting $E_c/y_c = 3/2 = 1 + \mathbf{F}_c^2/2$, or $\mathbf{F} = 1$,

$\mathbf{F} < 1$	Flow is subcritical
$\mathbf{F} = 1$	Flow is critical
$\mathbf{F} > 1$	Flow is supercritical

It is seen that for open-channel flow the Froude number determines the type of flow in the same manner as Mach number for compressible flow.

EXAMPLE. Water flows at a ate of 600 ft^3/s in a rectangular channel 10 ft wide at a depth of 4 ft. Determine (1) specific energy and (2) type of flow.

1. from the continuity equation,

$$V = Q/A = 600/(10 \times 4) = 15 \text{ ft/s}$$
$$E = y + V^2/2g = 4 + (15)^2/2(2 \times 32.17) = 7.497 \text{ ft}$$

2. $\mathbf{F} = V/\sqrt{gy} = 15/\sqrt{32.17 \times 4} = 1.322$; $\mathbf{F} > 1$ $\therefore$ flow is supercritical.

FLOW OF LIQUIDS FROM TANK OPENINGS

Steady State Consider the jet whose velocity is V discharging from an open tank through an opening whose area is a, as shown in Fig. 3.3.35. The liquid height above the centerline is h, and the cross-sectional area of the tank at h is A. The ideal velocity of the jet is $V_i = \sqrt{2gh}$. The ratio of the actual velocity V to the ideal velocity V_i is the **coefficient of velocity** Cv, or $V = C_v V_i = C_v\sqrt{2gh}$. The ratio of the actual opening a to the minimum area of the jet a_c is the **coefficient of contraction** C_c, or $a = C_c a_c$. The ratio of the actual discharge Q to the ideal discharge Q_i is the **coefficient of discharge** C, or $Q = CQ_i = C_a V_i = C_c C_v a\sqrt{2gh}$, and $C = C_c C_v$. Nominal values of coefficients for various openings are given in Fig. 3.3.36.

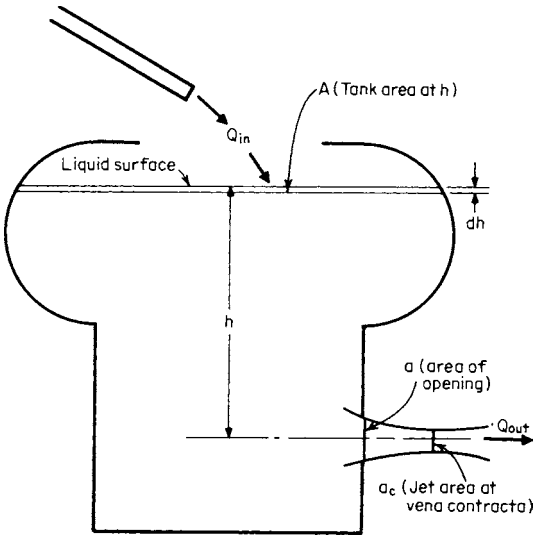

Fig. 3.3.35 Notation for tank flow.

Unsteady State If the rate of liquid entering the tank Q_{in} is different from that leaving, the level h in the tank will change because of the change in storage. For liquids, the conservation-of-mass equation may be written as $Q_{in} - Q_{out} = Q_{stored}$; for a time interval dt, $(Q_{in} - Q_{out})\,dt = A\,dh$,

Type	Coefficient		
	c	c_c	c_v
Sharp-edged orifice	0.61	0.62	0.98
Rounded-edged orifice	0.98	1.00	0.98
Short tube, $\frac{L}{D} \sim 1$	0.80	1.00	0.80
Borda	0.51	0.52	0.98

Fig. 3.3.36 Nominal coefficients of orifices.

neglecting fluid acceleration,

$$Q_{\text{out}}\,dt = Ca\sqrt{2gh}\,dt, \text{ or } (Q_{\text{in}} - Ca\sqrt{2gh})\,dt = A\,dh, \text{ or } \int_{t_1}^{t_2} dt = \int_{h_1}^{h_2} \frac{A\,dh}{Q_{\text{in}} - Q_{\text{out}}} = \int_{h_1}^{h_2} \frac{A\,dh}{Q_{\text{in}} - Ca\sqrt{2gh}}$$

EXAMPLE. An open cylindrical tank is 6 ft in diameter and is filled with water to a depth of 10 ft. A 4-in-diameter sharp-edged orifice is installed on the bottom of the tank. A pipe on the top of the tank supplies water at the rate of 1 ft³/s. Estimate (1) the steady-state level of this tank, (2) the time required to reduce the tank level by 2 ft.

1. *Steady-state level.* From Fig. 3.3.36, $C = 0.61$ for a sharp-edged orifice, $a = (\pi/4)d^2 = (\pi/4)(4/12)^2 = 0.08727$ ft². For steady state, $Q_{\text{in}} = Q_{\text{out}} = Ca\sqrt{2gh} = 1 = (0.61)(0.08727)(2 \times 32.17h)^{1/2}$; $h = 5.484$ ft.

2. Time required to lower level 2 ft, $A = (\pi/4)D^2 = (\pi/4)(6)^2 = 28.27$ ft²

$$t_2 - t_1 = \int_{h_1}^{h_2} \frac{A\,dh}{Q_{\text{in}} - Ca\sqrt{2gh}}$$

This equation may be integrated by letting $Q = Ca\sqrt{2g}h^{1/2}$; then $dh = 2Q\,dQ/(Ca\sqrt{2g})^2$; then

$$t_2 - t_1 = \frac{2A}{(Ca\sqrt{2g})^2}\left[Q_{\text{in}}\log_e\left(\frac{Q_{\text{in}} - Q_1}{Q_{\text{in}} - Q_2}\right) + Q_1 - Q_2\right]$$

At t_1: $Q_1 = 0.61 \times 0.08727\sqrt{2 \times 32.17 \times 10} = 1.350$ ft³/s

At t_2: $Q_2 = 0.61 \times 0.08727\sqrt{2 \times 32.17 \times 8} = 1.208$ ft³/s

$$t_2 - t_1 = \frac{2 \times 28.27}{(0.61 \times 0.08727\sqrt{2 \times 32.17})^2} \times \left[(1)\log_e\left(\frac{1 - 1.350}{1 - 1.208}\right) + 1.350 - 1.208\right]$$

$t_2 - t_1 = 205.4$ s

WATER HAMMER

Equations Water hammer is the series of shocks, sounding like hammer blows, produced **by suddenly reducing the flow** of a fluid in a pipe. Consider a fluid flowing frictionlessly in a rigid pipe of uniform area A with a velocity V. The pipe has a length L, and inlet pressure p_1 and a pressure p_2 at L. At length L, there is a valve which can suddenly reduce the velocity at L to $V - \Delta V$. The equivalent mass rate of flow of a pressure wave traveling at sonic velocity c, $M = \rho Ac$. From the impulse-momentum equation, $M(V_2 - V_1) = p_2A_2 - p_1A_1$; for this application, $(\rho Ac)(V - \Delta V - V) = p_2A - p_1A$, or the increase in pressure $\Delta p = -\rho c\Delta V$. When the liquid is flowing in an elastic pipe, the equation for pressure rise must be modified to account for the expansion of the pipe; thus

$$c = \sqrt{\frac{E_s}{\rho[1 + (E_s/E_p)(D_o + D_i)/(D_o - D_i)]}}$$

where ρ = mass density of the fluid, E_s = bulk modulus of elasticity of the fluid, E_p = modulus of elasticity of the pipe material, D_o = outside diameter of pipe, and D_i = inside diameter of pipe.

Time of Closure The time for a pressure wave to travel the length of pipe L and return is $t = 2L/c$. If the time of closure $t_c \leq t$, the approximate pressure rise $\Delta p \approx -2\,\rho V(L/t_c)$. When it is not feasible to close the valve slowly, **air chambers** or **surge tanks** may be used to absorb all or most of the pressure rise. Water hammer can be very dangerous. See Sec. 9.9.

EXAMPLE. Water flows at 68°F (20°C) in a 3-in steel schedule 40 pipe at a velocity of 10 ft/s. A valve located 200 ft downstream is suddenly closed. Determine (1) the increase in pressure considering pipe to be rigid, (2) the increase considering pipe to be elastic, and (3) the maximum time of valve closure to be considered "sudden."

For water, $\rho = -1.937$ slugs/ft³ $= 1.937$ lb · sec²/ft⁴; $E_s = 319{,}000$ lb/in²; $E_p = 28.5 \times 10^6$ lb/in² (Secs. 5.1 and 6); $c = 4{,}860$ ft/s; from Sec. 8.7, $D_o = 3.5$ in, $D_i = 3.068$ in.

1. *Inelastic pipe*

$$\Delta p = -\rho c\Delta V = -(1.937)(4{,}860)(-10) = 94{,}138 \text{ lbf/ft}^2 = 94{,}138/144 = 653.8 \text{ lbf/in}^2\,(4.507 \times 10^6 \text{ N/m}^2)$$

2. *Elastic pipe*

$$c = \sqrt{\frac{E_s}{\rho[1 + (E_s/E_p)(D_o + D_i)/(D_o - D_i)]}} = \sqrt{\frac{319{,}000 \times 144}{1.937\left[1 + \dfrac{(319{,}000/28.5 \times 10^6)(3.500 + 3.067)}{(3.500 - 3.067)}\right]}} = 4{,}504$$

$$\Delta p = -(1.937)(4{,}504)(-10) = 87{,}242 \text{ lbf/ft}^2 = 605.9 \text{ lbf/in}^2\,(4.177 \times 10^6 \text{ N/m}^2)$$

3. *Maximum time for closure*

$$t = 2L/c = 2 \times 200/4{,}860 = 0.08230 \text{ s or less than } 1/10 \text{ s}$$

COMPUTATIONAL FLUID DYNAMICS (CFD)

The partial differential equations of fluid motion are very difficult to solve. CFD methods are utilized to provide discrete approximations for the solution of those equations. A brief introduction to CFD is included in Section 20.6. The references therein will guide the reader further.

3.4 VIBRATION

by Leonard Meirovitch

SINGLE-DEGREE-OF-FREEDOM SYSTEMS

Discrete System Components A system is defined as an aggregation of components acting together as one entity. The components of a vibratory mechanical system are of three different types, and they relate forces to displacements, velocities, and accelerations. The component relating forces to displacements is known as a spring (Fig. 3.4.1*a*). For a **linear spring** the force F_s is proportional to the elongation $\delta = x_2 - x_1$, or

$$F_s = k\delta = k(x_2 - x_1) \tag{3.4.1}$$

where k represents the **spring constant,** or the **spring stiffness,** and x_1 and x_2 are the displacements of the end points. The component relating forces to velocities is called a **viscous damper** or a **dashpot** (Fig. 3.4.1b). It consists of a piston fitting loosely in a cylinder filled with liquid so that the liquid can flow around the piston when it moves relative to the cylinder. The relation between the damper force and the velocity of the piston relative to the cylinder is

$$F_d = c(\dot{x}_2 - \dot{x}_1) \tag{3.4.2}$$

in which c is the **coefficient of viscous damping;** note that dots denote derivatives with respect to time. Finally, the relation between forces and accelerations is given by Newton's second law of motion:

$$F_m = m\ddot{x} \tag{3.4.3}$$

where m is the **mass** (Fig. 3.4.1c).

The spring constant k, coefficient of viscous damping c, and mass m represent physical properties of the components and are the **system parameters.** By implication, these properties are concentrated at points,

thus they are **lumped,** or **discrete, parameters.** Note that springs and dampers are assumed to be massless and masses are assumed to be rigid.

Springs can be arranged in parallel and in series. Then, the proportionality constant between the forces and the end points is known as an

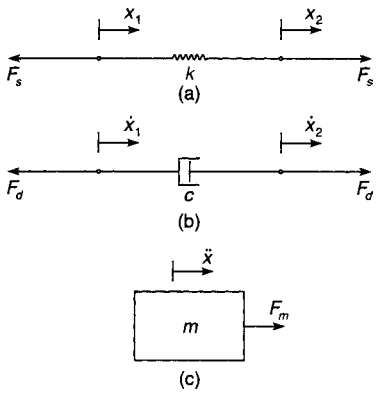

Fig. 3.4.1

equivalent spring constant and is denoted by k_{eq}, as shown in Table 3.4.1. Certain elastic components, although distributed over a given line segment, can be regarded as lumped with an equivalent spring constant given by $k_{eq} = F/\delta$, where δ is the deflection at the point of application of the force F. A similar relation can be given for springs in torsion. Table 3.4.1 lists the equivalent spring constants for a variety of components.

Equation of Motion The dynamic behavior of many engineering systems can be approximated with good accuracy by the **mass-damper-spring model** shown in Fig. 3.4.2. Using Newton's second law in conjunction with Eqs. (3.4.1)–(3.4.3) and measuring the displacement $x(t)$ from the static equilibrium position, we obtain the differential equation of motion

$$m\ddot{x}(t) + c\dot{x}(t) + kx(t) = F(t) \tag{3.4.4}$$

which is subject to the **initial conditions** $x(0) = x_0$, $\dot{x}(0) = v_0$, where x_0 and v_0 are the **initial displacement** and **initial velocity,** respectively. Equation (3.4.4) is in terms of a single coordinate. namely $x(t)$; the system of Fig. 3.4.2 is therefore said to be a **single-degree-of-freedom system.**

Free Vibration of Undamped Systems Assuming zero damping and external forces and dividing Eq. (3.4.4) through by m, we obtain

$$\ddot{x} + \omega_n^2 x = 0 \qquad \omega_n = \sqrt{k/m} \tag{3.4.5}$$

In this case, the vibration is caused by the initial excitations alone. The solution of Eq. (3.4.5) is

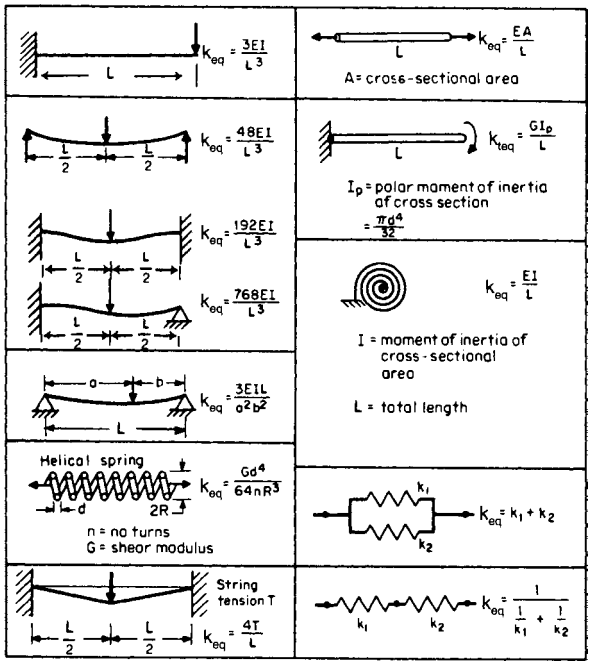
$$x(t) = A\cos(\omega_n t - \phi) \tag{3.4.6}$$

which represents **simple sinusoidal,** or **simple harmonic oscillation** with **amplitude** A, **phase angle** ϕ, and **frequency**

$$\omega_n = \sqrt{k/m} \qquad \text{rad/s} \tag{3.4.7}$$

Systems described by equations of the type (3.4.5) are called **harmonic oscillators.** Because the frequency of oscillation represents an inherent property of the system, independent of the initial excitation, ω_n is called the **natural frequency.** On the other hand, the amplitude and

Table 3.4.1 Equivalent Spring Constants



phase angle do depend on the initial displacement and velocity, as follows:

$$A = \sqrt{x_0^2 + (v_0/\omega_n)^2} \qquad \phi = \tan^{-1} v_0/x_0\omega_n \tag{3.4.8}$$

The time necessary to complete one cycle of motion defines the **period**

$$T = 2\pi/\omega_n \qquad \text{seconds} \tag{3.4.9}$$

The reciprocal of the period provides another definition of the **natural frequency,** namely,

$$f_n = \frac{1}{T} = \frac{\omega_n}{2\pi} \qquad \text{Hz} \tag{3.4.10}$$

where Hz denotes *hertz* [1 Hz = 1 cycle per second (cps)].

A large variety of vibratory systems behave like harmonic oscillators, many of them when restricted to small amplitudes. Table 3.4.2 shows a variety of harmonic oscillators together with their respective natural frequency.

Free Vibration of Damped Systems Let $F(t) = 0$ and divide through by m. Then, Eq. (3.4.4) reduces to

$$\ddot{x}(t) + 2\zeta\omega_n\dot{x}(t) + \omega_n^2 x(t) = 0 \tag{3.4.11}$$

where

$$\zeta = c/2m\omega_n \tag{3.4.12}$$

is the **damping factor,** a nondimensional quantity. The nature of the motion depends on ζ. The most important case is that in which $0 < \zeta < 1$.

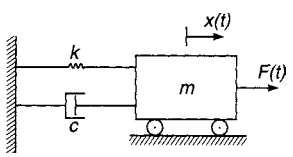


Fig. 3.4.2

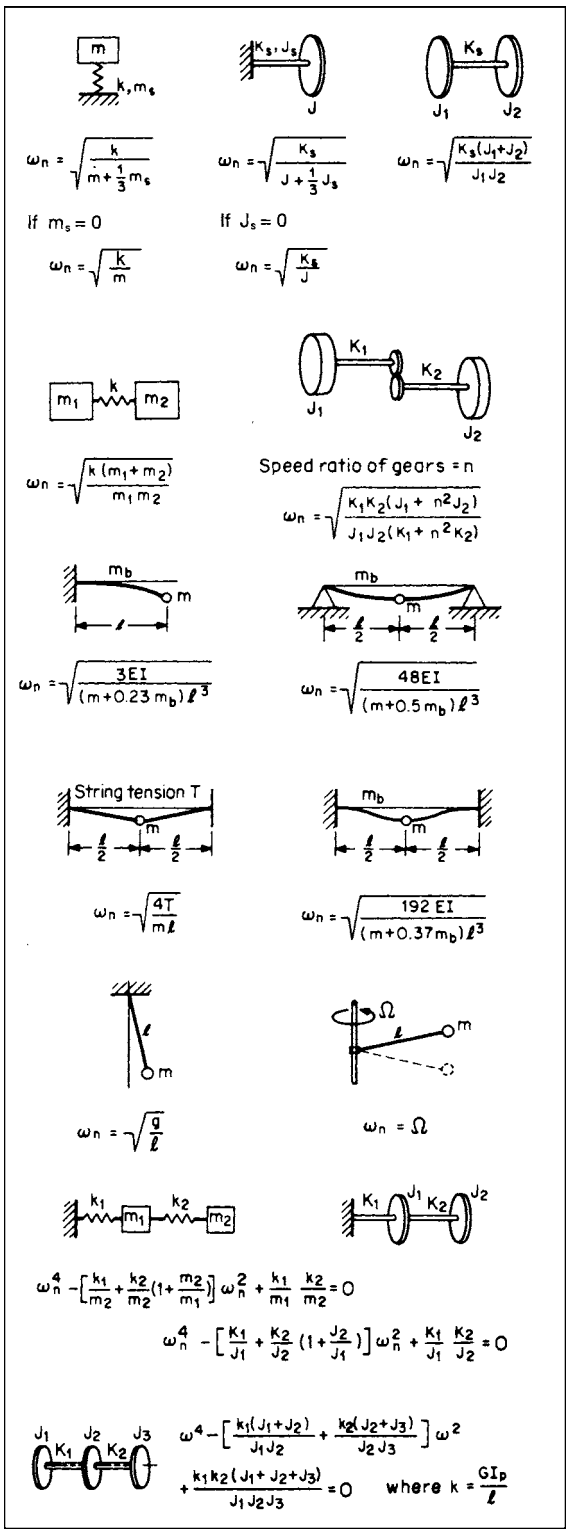
Table 3.4.2 Harmonic Oscillators and Natural Frequencies



In this case, the system is said to be **underdamped** and the solution of Eq. (3.4.11) is

$$x(t) = Ae^{-\zeta\omega_n t}\cos(\omega_d t - \phi) \tag{3.4.13}$$

where

$$\omega_d = (1 - \zeta^2)^{1/2}\omega_n \tag{3.4.14}$$

is the **frequency of damped free vibration** and

$$T = 2\pi/\omega_d \tag{3.4.15}$$

is the **period of damped oscillation.** The amplitude and phase angle depend on the initial displacement and velocity, as follows:

$$A = \sqrt{x_0^2 + (\zeta\omega_n x_0 + v_0)^2/\omega_d^2} \quad \phi = \tan^{-1}(\zeta\omega_n x_0 + v_0)/x_0\omega_d \tag{3.4.16}$$

The motion described by Eq. (3.4.13) represents **decaying oscillation,** where the term $Ae^{-\zeta\omega_n t}$ can be regarded as a time-dependent amplitude, providing an envelope bounding the harmonic oscillation.

When $\zeta \geq 1$, the solution represents **aperiodic decay.** The case $\zeta = 1$ represents **critical damping,** and

$$c_c = 2m\omega_n \tag{3.4.17}$$

is the **critical damping coefficient,** although there is nothing critical about it. It merely represents the borderline between oscillatory decay and aperiodic decay. In fact, c_c is the smallest damping coefficient for which the motion is aperiodic. When $\zeta > 1$, the system is said to be **overdamped.**

Logarithmic Decrement Quite often the damping factor is not known and must be determined experimentally. In the case in which the system is underdamped, this can be done conveniently by plotting $x(t)$ versus t (Fig. 3.4.3) and measuring the response at two different times

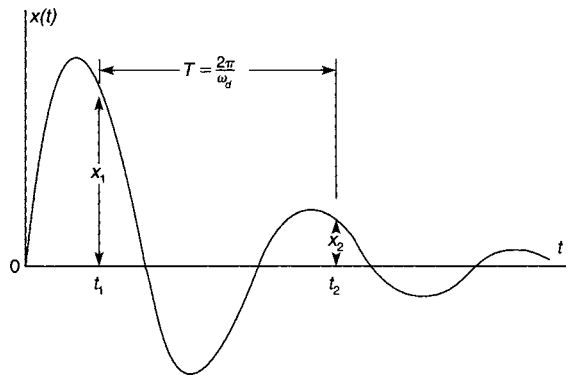


Fig. 3.4.3

separated by a complete period. Let the times be t_1 and $t_1 + T$, introduce the notation $x(t_1) = x_1$, $x(t_1 + T) = x_2$, and use Eq. (3.4.13) to obtain

$$\frac{x_1}{x_2} = \frac{Ae^{-\zeta\omega_n t_1}\cos(\omega_d t_1 - \phi)}{Ae^{-\zeta\omega_n(t_1+T)}\cos[\omega_d(t_1 + T) - \phi]} = e^{\zeta\omega_n T} \tag{3.4.18}$$

where $\cos[\omega_d(t_1 + T) - \phi] = \cos(\omega_d t_1 - \phi + 2\pi) = \cos(\omega_d t_1 - \phi)$. Equation (3.4.18) yields the **logarithmic decrement**

$$\delta = \ln\frac{x_1}{x_2} = \zeta\omega_n T = \frac{2\pi\zeta}{\sqrt{1 - \zeta^2}} \tag{3.4.19}$$

which can be used to obtain the damping factor

$$\zeta = \frac{\delta}{\sqrt{(2\pi)^2 + \delta^2}} \tag{3.4.20}$$

For small damping, the logarithmic decrement is also small, and the damping factor can be approximated by

$$\zeta \approx \frac{\delta}{2\pi} \tag{3.4.21}$$

Response to Harmonic Excitations Consider the case in which the excitation force $F(t)$ in Eq. (3.4.4) is harmonic. For convenience, express $F(t)$ in the form $kA\cos\omega t$, where k is the spring constant, A is an amplitude with units of displacement and ω is the **excitation frequency.** When divided through by m, Eq. (3.4.4) has the form

$$\ddot{x} + 2\zeta\omega_n\dot{x} + \omega_n^2 x = \omega_n^2 A\cos\omega t \tag{3.4.22}$$

The solution of Eq. (3.4.22) can be expressed as

$$x(t) = A|G(\omega)|\cos(\omega t - \phi) \tag{3.4.23}$$

where

$$|G(\omega)| = \frac{1}{\sqrt{[1 - (\omega/\omega_n)^2]^2 + (2\zeta\omega/\omega_n)^2}} \tag{3.4.24}$$

is a **nondimensional magnitude factor*** and

$$\phi(\omega) = \tan^{-1}\frac{2\zeta\omega/\omega_n}{1 - (\omega/\omega_n)^2} \tag{3.4.25}$$

is the phase angle; note that both the magnitude factor and phase angle depend on the excitation frequency ω.

Equation (3.4.23) shows that the response to harmonic excitation is also harmonic and has the same frequency as the excitation, but different amplitude $A|G(\omega)|$ and phase angle $\phi(\omega)$. Not much can be learned by plotting the response as a function of time, but a great deal of information can be gained by plotting $|G|$ versus ω/ω_n and ϕ versus ω/ω_n. They are shown in Fig. 3.4.4 for various values of the damping factor ζ.

In Fig. 3.4.4, for low values of ω/ω_n, the nondimensional magnitude factor $|G(\omega)|$ approaches unity and the phase angle $\phi(\omega)$ approaches zero. For large values of ω/ω_n, the magnitude approaches zero (see accompanying footnote about magnification factor) and the phase angle approaches 180°. The magnitude experiences peaks for $\omega/\omega_n = \sqrt{1 - 2\zeta^2}$, provided $\zeta < 1/\sqrt{2}$. The peak values are $|G(\omega)|_{\max} = 1/2\zeta\sqrt{1 - \zeta^2}$. For small ζ, the peaks occur approximately at $\omega/\omega_n = 1$ and have the approximate values $|G(\omega)|_{\max} = Q \approx 1/2\zeta$, where Q is known as the **quality factor.** In such cases, the phase angle tends to 90°. Clearly, for small ζ the system experiences large-amplitude vibration, a condition known as **resonance.** The points P_1 and P_2, where $|G|$ falls to $Q/\sqrt{2}$, are called **half-power points.** The increment of frequency associated with the half-power points P_1 and P_2 represents the **bandwidth** $\Delta\omega$ of the system. For small damping, it has the value

$$\Delta\omega = \omega_2 - \omega_1 \approx 2\zeta\omega_n \tag{3.4.26}$$

The case $\zeta = 0$ deserves special attention. In this case, referring to Eq. (3.4.22), the response is simply

$$x(t) = \frac{A}{1 - (\omega/\omega_n)^2}\cos\omega t \tag{3.4.27}$$

For $\omega/\omega_n < 1$, the displacement is in the same direction as the force, so that the phase angle is zero; the **response is in phase** with the excitation. For $\omega/\omega_n > 1$, the displacement is in the direction opposite to the force, so that the phase angle is 180° **out of phase** with the excitation. Finally, when $\omega = \omega_n$ the response is

$$x(t) = \frac{A}{2}\omega_n t\sin\omega_n t \tag{3.4.28}$$

This is typical of the **resonance** condition, when the response increases without bounds as time increases. Of course, at a certain time the displacement becomes so large that the spring ceases to be linear, thus violating the original assumption and invalidating the solution. In practical terms, unless the excitation frequency varies, passing quickly through $\omega = \omega_n$, the system can break down.

When the excitation is $F(t) = kA\sin\omega t$, the response is

$$x(t) = A|G(\omega)|\sin(\omega t - \phi) \tag{3.4.29}$$

* The term $|G(\omega)|$ is often referred to *magnification factor,* but this is a misnomer, as we shall see shortly.

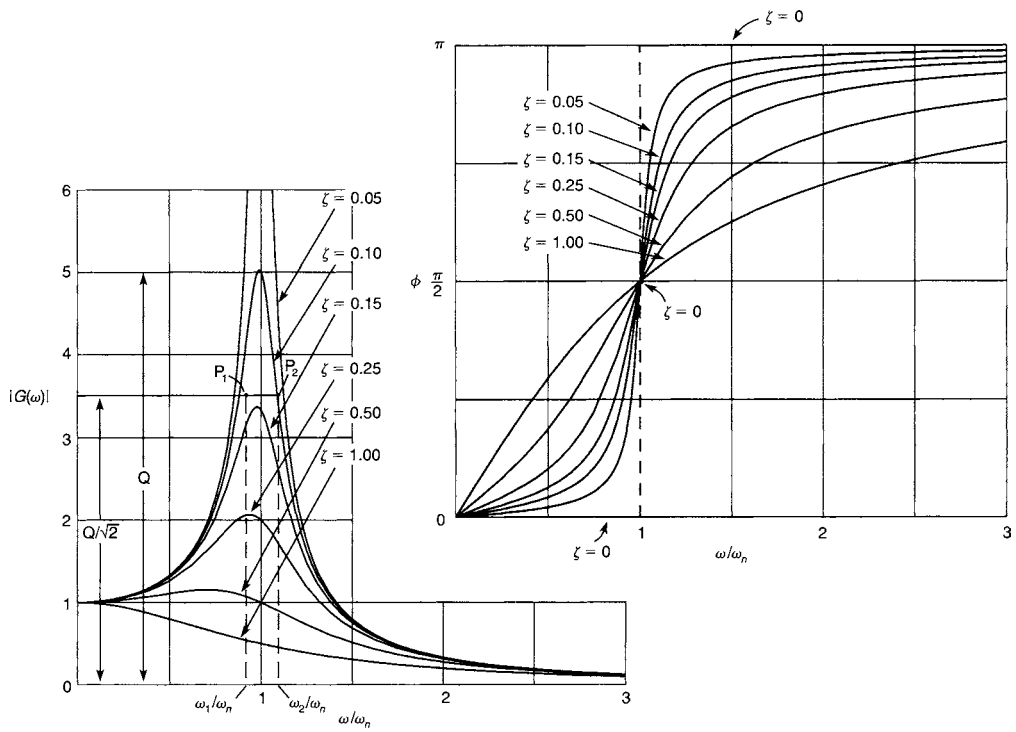

Fig. 3.4.4 Frequency response plots.

One concludes that in **harmonic response,** time plays a secondary role to the frequency. In fact, the only significant information is extracted from the magnitude and phase angle plots of Fig. 3.4.4. They are referred to as **frequency-response plots.**

Since time plays no particular role, the harmonic response is called **steady-state response.** In general, for linear systems with constant parameters, such as the mass-damper-spring system under consideration, the response to the initial excitations is added to the response to the excitation forces. The response to initial excitations, however, represents **transient response.** This is due to the fact that every system possesses some amount of damping, so that the response to initial excitations disappears with time. In contrast, steady-state response persists with time. Hence, in the case of harmonic excitations, it is meaningless to add the response to initial excitations to the harmonic response.

Vibration Isolation A problem of great interest is the magnitude of the force transmitted to the base by a system of the type shown in Fig. 3.4.2 subjected to harmonic excitation. This force is a combination of the spring force kx and the dashpot force $c\dot{x}$. Recalling Eq. (3.4.23), write

$$\begin{aligned} kx &= kA|G|\cos(\omega t - \phi) \\ c\dot{x} &= -c\omega A|G|\sin(\omega t - \phi) \\ &= c\omega A|G|\cos\left(\omega t - \phi + \frac{\pi}{2}\right) \end{aligned} \tag{3.4.30}$$

so that the dashpot force is 90° out of phase with the spring force. Hence, the magnitude of the force is

$$\begin{aligned} F_{\text{tr}} &= \sqrt{(kA|G|)^2 + (c\omega A|G|)^2} = kA|G|\sqrt{1 + (c\omega/k)^2} \\ &= kA|G|\sqrt{1 + (2\zeta\omega/\omega_n)^2} \end{aligned} \tag{3.4.31}$$

Let the magnitude of the harmonic excitation be $F_0 = kA$; the measure of the force transmitted to the base is then

$$\begin{aligned} T = \frac{F_{\text{tr}}}{F_0} &= |G|\sqrt{1 + (2\zeta\omega/\omega_n)^2} \\ &= \sqrt{\frac{1 + (2\zeta\omega/\omega n)^2}{[1 - (\omega/\omega_n)^2]^2 + (2\zeta\omega/\omega_n)^2}} \end{aligned} \tag{3.4.32}$$

which represents a nondimensional ratio called **transmissibility.** Figure 3.4.5 plots F_{tr}/F_0 versus ω/ω_n for various values of ζ.

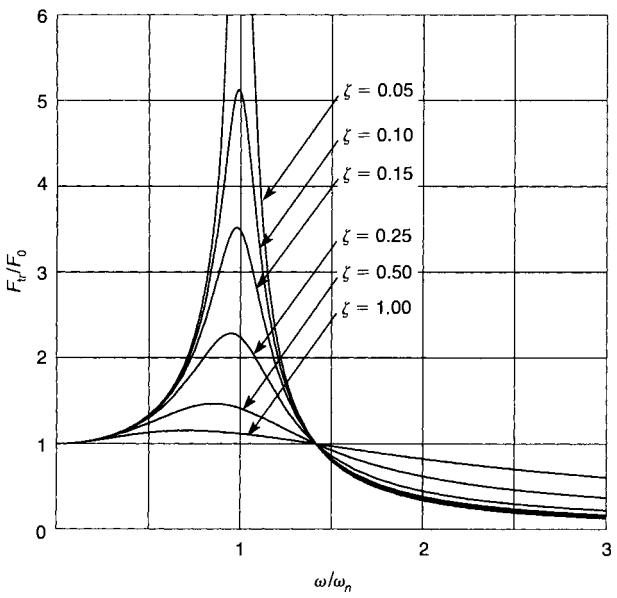

Fig. 3.4.5

The transmissibility is less than 1 for $\omega/\omega_n > \sqrt{2}$, and decreases as ω/ω_n increases. Hence, for **an isolator to perform well,** its natural frequency must be much smaller than the excitation frequency. However, for very low natural frequencies, difficulties can be encountered in isolator design. Indeed, the natural frequency is related to the static deflection δ_{st} by $\omega_n = \sqrt{k/m} = \sqrt{g/\delta_{\text{st}}}$, where g is the gravitational constant. For the natural frequency to be sufficiently small, the static deflection may have to be impractically large. The relation between the excitation frequency f measured in rotations per minute and the static deflection δ_{st} measured in inches is

$$f = 187.7\sqrt{\frac{2 - R}{\delta_{\text{st}}(1 - R)}} \quad \text{rpm} \tag{3.4.33}$$

where $R = 1 - T$ **represents the percent reduction** in vibration. Figure 3.4.6 shows a logarithmic plot of f versus δ_{st} with R as a parameter.

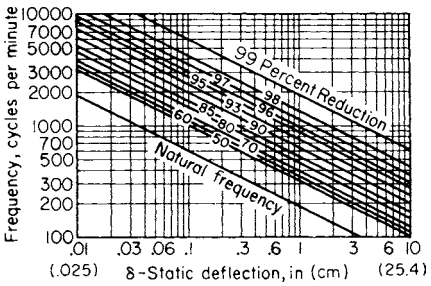

Fig. 3.4.6

Figure 3.4.7 depicts two types of isolators. In Fig. 3.4.7*a*, isolation is accomplished by means of springs and in Fig. 3.4.7*b* by rubber rings supporting the bearings. Isolators of all shapes and sizes are available commercially.

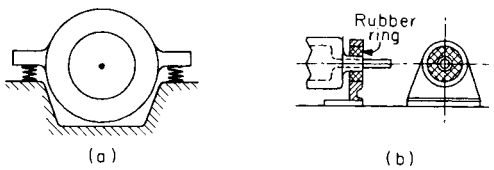

Fig. 3.4.7

Rotating Unbalanced Masses Many appliances, machines, etc., involve components spinning relative to a main body. A typical example is the clothes dryer. Under certain circumstances, the mass of the spinning component is not symmetric relative to the center of rotation, as when the clothes are not spread uniformly in the spinning drum, giving rise to harmonic excitation. The behavior of such systems can be simulated adequately by the single-degree-of-freedom model shown in Fig. 3.4.8, which consists of a main mass $M - m$, supported by two springs of combined stiffness k and a dashpot with coefficient of viscous damping c, and two eccentric masses $m/2$ rotating in opposite sense with the constant angular velocity ω. Although there are three masses, the motion of the eccentric masses relative to the main mass is prescribed, so that there is only one degree of freedom. The equation of motion for the system is

$$M\ddot{x} + c\dot{x} + kx = m/\omega^2 \sin \omega t \tag{3.4.34}$$

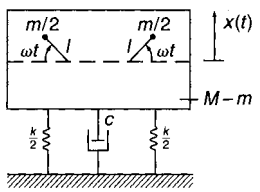

Fig. 3.4.8

Using the analogy with Eq. (3.4.29), the solution of Eq. (3.4.34) is

$$x(t) = \frac{m}{M} l \left(\frac{\omega}{\omega_n}\right)^2 |G(\omega)| \sin(\omega t - \phi) \qquad \omega_n^2 = \frac{k}{M} \quad (3.4.35)$$

The magnitude factor in this case is $(\omega/\omega_n)^2|G(\omega)|$, where $|G(\omega)|$ is given by Eq. (3.4.24); it is plotted in Fig. 3.4.9. On the other hand, the phase angle remains as in Fig. 3.4.4.

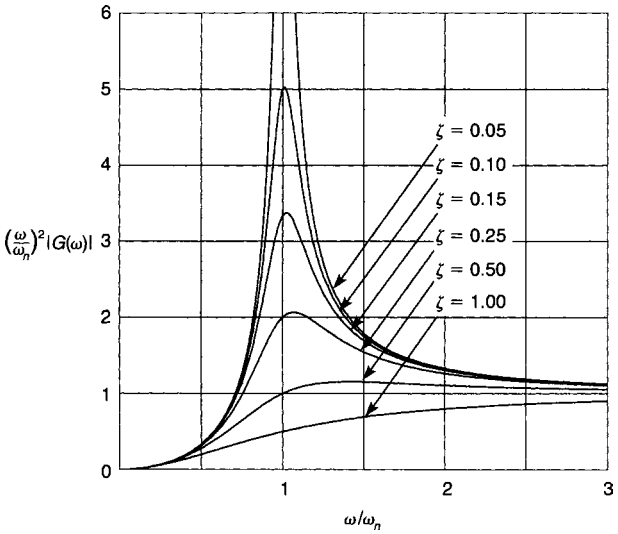

Fig. 3.4.9

Whirling of Rotating Shafts Many mechanical systems involve rotating shafts carrying disks. If the disk has some eccentricity, then the centrifugal forces cause the shaft to bend, as shown in Fig. 3.4.10*a*. The rotation of the plane containing the bent shaft about the bearing axis is called **whirling.** Figure 3.4.10*b* shows a disk with the body axes x, y rotating about the origin O with the angular velocity ω. The geometrical

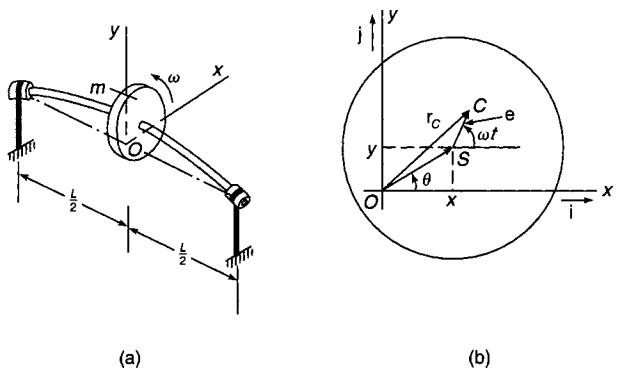

Fig. 3.4.10

center of the disk is denoted by S and the mass center by C. The distance between the two points is the eccentricity e. The shaft is massless and of stiffness k_{eq} and the disk is rigid and of mass m. The x and y components of the displacement of S relative to O are independent from one another and, for no damping, satisfy the equations of motion

$$\ddot{x} + \omega_n^2 x = e\omega^2 \cos \omega t \qquad \ddot{y} + \omega_n^2 y = e\omega^2 \sin \omega t \qquad \omega_n^2 = k_{eq}/m \quad (3.4.36)$$

where, assuming that the shaft is simply supported (see Table 3.4.1), $k_{eq} = 48EI/L^3$, in which E is the modulus of elasticity, I the cross-sectional area moment of inertia, and L the length of the shaft. By analogy with Eq. (3.4.27), Eqs. (3.4.36) have the solution

$$x(t) = \frac{e(\omega/\omega_n)^2}{1 - (\omega/\omega_n)^2} \cos \omega t \qquad y(t) = \frac{e(\omega/\omega_n)^2}{1 - (\omega/\omega_n)^2} \sin \omega t \quad (3.4.37)$$

Clearly, resonance occurs when the whirling angular velocity coincides with the natural frequency. In terms of rotations per minute, it has the value

$$f_c = \frac{60}{2\pi} \omega_n = \frac{60}{2\pi} \sqrt{\frac{48EI}{mL^3}} \qquad \text{rpm} \quad (3.4.38)$$

where f_c is called the **critical speed.**

Structural Damping Experience shows that energy is dissipated in all real systems, including those assumed to be undamped. For example, because of internal friction, energy is dissipated in real springs undergoing cyclic stress. This type of damping is called **structural damping** or **hysteretic damping** because the energy dissipated in one cycle of stress is equal to the area inside the hysteresis loop. Systems possessing structural damping and subjected to harmonic excitation with the frequency ω can be treated as if they possess viscous damping with the equivalent coefficient

$$c_{eq} = \alpha/\pi\omega \quad (3.4.39)$$

where α is a material constant. In this case, the equation of motion is

$$m\ddot{x} + \frac{\alpha}{\pi\omega}\dot{x} + kx = kA \cos \omega t \quad (3.4.40)$$

The solution of Eq. (3.4.40) is

$$x(t) = A|G| \cos(\omega t - \phi) \quad (3.4.41)$$

where this time the magnitude factor and phase angle have the values

$$G = \frac{1}{\sqrt{[1 - (\omega/\omega_n)^2]^2 + \gamma^2}} \qquad \phi = \tan^{-1} \frac{\gamma\omega_n^2}{\omega[1 - (\omega/\omega_n)^2]} \quad (3.4.42)$$

in which

$$\gamma = \frac{\alpha}{\pi k} \quad (3.4.43)$$

is known as the **structural damping factor.** One word of caution is in order: **the analogy between structural and viscous damping is valid only for harmonic excitation.**

Balancing of Rotating Machines Machines such as electric motors and generators, turbines, compressors, etc. contain rotors with journals supported by bearings. In many cases, the rotors rotate relative to the bearings at very high rates, reaching into tens of thousands of revolutions per minute. Ideally the rotor is rigid and the axis of rotation coincides with one of its principal axes; by implication, the rotor center of mass lies on the axis of rotation. Such a rotor does not wobble and the only forces exerted on the bearings are due to the weight of the rotor. Such a rotor is said to be **perfectly balanced.** These ideal conditions are seldom realized, and in practice the mass center lies at a distance e (eccentricity) from the axis of rotation, so that there is a net centrifugal force $F = me\omega^2$ acting on the rotor, where m is the mass of the rotor and ω is the rotational speed. This centrifugal force is balanced by reaction forces in the bearings, which tend to wear out the bearings with time.

The rotor unbalance can be divided into two types, static and dynamic. Static unbalance can be detected by placing the rotor on a pair of parallel rails. Then, the mass center will settle in the lowest position in a vertical plane through the rotation axis and below this axis. To balance the rotor statically, it is necessary to add a mass m' in the same plane at a distance r from the rotation axis and above this axis, where m' and r must be such that $m'r = me$. In this manner, the net centrifugal force on the rotor is zero. The net result of **static balancing** is to cause the mass center to coincide with the rotation axis, so that the rotor will remain in any position placed on the rails. However, unless the mass m' is placed

on a line containing m and at right angles with the bearings axis, the centrifugal forces on m and m' will form a couple (Fig. 3.4,11), Static balancing is suitable when the rotor is in the form of a thin disk, in which case the couple tends to be small. Automobile tires are at times balanced statically, although strictly speaking they are neither thin nor rigid.

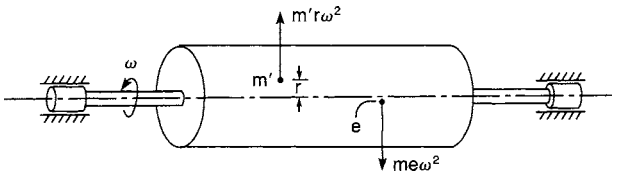

Fig. 3.4.11

In general, for practical reasons, the mass m' cannot be placed on an axis containing m and perpendicular to the bearing axis. Hence, although in static balancing the mass center lies on the rotation axis, the rotor principal axis does not coincide with the bearing axis, as shown in Fig. 3.4.12, causing the rotor to wobble during rotation. In this case, the rotor is said to be **dynamically unbalanced.** Clearly, it is highly desirable to place the mass m' so that the rotor is both statically and dynamically balanced. In this regard, note that the end planes of the rotor are

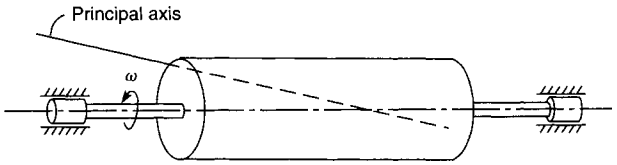

Fig. 3.4.12

convenient locations to place correcting masses. In Fig. 3.4.13, if the mass center is at a distance a from the right end, then **dynamic balance** can be achieved by placing masses $m'a/L$ and $m'(L - a)/L$ on the intersection of the plane of unbalance and the rotor left end plane and right end plane, respectively. In this manner, the resultant centrifugal force is zero

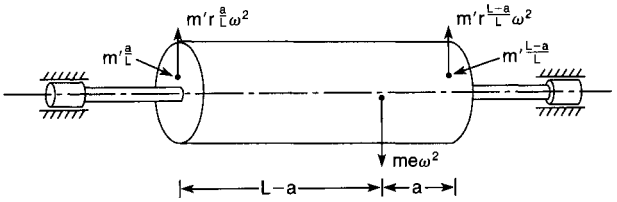

Fig. 3.4.13

and the two couples thus created are equal in value to $m'a(L - a)\omega^2/L$ and opposite in sense, so that they cancel each other. This results in a rotor completely balanced, i.e., balanced statically and dynamically.

The task of determining the magnitude and position of the unbalance is carried out by means of a balancing machine provided with elastically supported bearings permitting the rotor to spin (Fig. 3.4.14). The unbalance causes the bearings to oscillate laterally so that electrical pickups and stroboflash light can measure the amplitude and phase of the rotor with respect to an arbitrary rotor.

In cases in which the rotor is very long and flexible. the position of the unbalance depends on the elastic configuration of the rotor, which in turn depends on the speed of rotation. temperature, etc. In such cases, it is necessary to balance the rotor under normal operating conditions by means of a portable balancing instrument.

Inertial Unbalance of Reciprocating Engines The crank-piston mechanism of a reciprocating engine produces dynamic forces capable of causing undesirable vibrations. Rotating parts, such as the crankshaft,

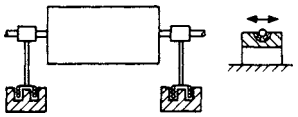

Fig. 3.4.14

can be balanced. However, translating parts, such as the piston, cannot be easily balanced, and the same can be said about the connecting rod, which executes a more complex motion of combined rotation and translation.

In the calculation of the unbalanced forces in a single-cylinder engine, the mass of the moving parts is divided into a reciprocating mass and a rotating mass. This is done by apportioning some of the mass of the connecting rod to the piston and some to the crank end. In general, this division of the connecting rod into two lumped masses tends to cause errors in the moment of inertia, and hence in the torque equation. On the other hand, the force equation can be regarded as being accurate. (See also Sec. 8.2.)

Assuming that the rotating mass is counterbalanced, only the reciprocating mass is of concern, and the inertia force for a single-cylinder engine is

$$F = m_{\text{rec}} r\omega^2 \cos \omega t + m_{\text{rec}} \frac{r^2}{L} \omega^2 \cos 2\omega t \tag{3.4.44}$$

where m_{rec} is the reciprocating mass, r the radius of the crank, ω the angular velocity of the crank, and L the length of the connecting rod. The first component on the right side, which alternates once per revolution, is denoted by X_1 and referred to as the **primary force,** and the second component, which is smaller and alternates twice per revolution, is denoted by X_2 and is called the **secondary force.**

In addition to the inertia force, there is an unbalanced torque about the crankshaft axis due to the reciprocating mass. However, this torque is considered together with the torque created by the power stroke, and the torsional oscillations resulting from these excitations can be mitigated by means of a pendulum-type absorber (see "Centrifugal Pendulum Vibration Absorbers" below) or a torsional damper.

The analysis for the single-cylinder engine can be extended to multicylinder in-line and V-block engines by superposition. For the in-line engine or one block of the V engine, the inertia force becomes

$$F = m_{\text{rec}} r\omega^2 \sum_{j=1}^{n} \cos(\omega t + \phi_j) + m_{\text{rec}} \frac{r^2}{L} \omega^2 \sum_{j=1}^{n} \cos 2(\omega t + \phi_j) \tag{3.4.45}$$

where ϕ_j is a phase angle corresponding to the crank position associated with cylinder j and n is the number of cylinders. The vibration force can be eliminated by proper spacing of the angular positions $\phi_j (j = 1, 2, \ldots, n)$.

Even if $F = 0$, there can be pitching and yawing moments due to the spacing of the cylinders. Table 3.4.3 gives the inertial unbalance and pitching of the primary and secondary forces for various crank-angle arrangements of n-cylinder engines.

Centrifugal Pendulum Vibration Absorbers For a rotating system, such as the crank mechanism just discussed, the exciting torques are proportional to the rotational speed ω, which varies over a wide range. Hence, for a vibration absorber to be effective, its natural frequency must be proportional to ω. The centrifugal pendulum shown in Fig. 3.4.15 is ideally suited to this task. Strictly speaking, the system of Fig. 3.4.15 represents a two-degree-of-freedom nonlinear system. However, assuming that the motion of the wheel consists of a steady rotation ω and a small harmonic oscillation at the frequency Ω, or

$$\theta(t) = \omega t + \theta_0 \sin \Omega t \tag{3.4.46}$$

Table 3.4.3 Inertial Unbalance of Four-Stroke-per-Cycle Engines

No. n of cylinders	Crank phase angle ϕ_j	Unbalanced forces		Unbalanced pitching moments about 1st cylinder	
		Primary	Secondary	Primary	Secondary
1		X_1	X_2	—	—
2	0–180°	0	$2X_2$	ℓX_1	$2\ell X_2$
4	0–180°–180°–0	0	$4X_2$	0	$6\ell X_2$
4	0–90°–270°–180°	0	0	$\ell X_1\sqrt{1+3^2}$	0
6	0–120°–240°–240°–120°–0	0	0	0	0
8	0–180°–90°–270°–270°–90°–180°–0	0	0	0	0
90° V-8	0–90°–270°–180°	0	0	Rotating primary couple of constant magnitude $\sqrt{10}\ell X_1$ which may be completely counterbalanced	

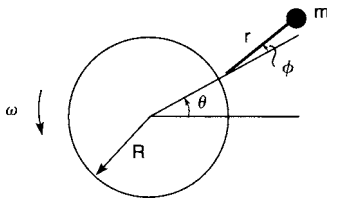

Fig. 3.4.15

and that the pendulum angle ϕ is relatively small, then the equation of motion of the pendulum reduces to the linear single-degree-of-freedom system

$$\ddot{\phi} + \omega_n^2\phi = \frac{R+r}{r}\Omega^2\theta_0 \sin \Omega t \tag{3.4.47}$$

where

$$\omega_n = \omega\sqrt{R/r} \tag{3.4.48}$$

is the natural frequency of the pendulum. The torque exerted by the pendulum on the wheel is

$$T = -\frac{m(R+r)^2}{1 - r\Omega^2/R\omega^2}\ddot{\theta} \tag{3.4.49}$$

so that the system behaves like a wheel with the effective mass moment of inertia

$$J_{\text{eff}} = -\frac{m(R+r)^2}{1 - r\Omega^2/R\omega^2} \tag{3.4.50}$$

which becomes infinite when Ω is equal to the natural frequency ω_n. To suppress disturbing torques of frequency Ω several times larger than the rotational speed ω, the ratio r/R must be very small, which requires a short pendulum. The **bifilar pendulum** depicted in Fig. 3.4.16, which consists of a U-shaped counterweight that fits loosely and rolls on two pins of radius r_2 within two larger holes of equal radius r_1, represents a suitable design whereby the effective pendulum length is $r = r_1 - r_2$.

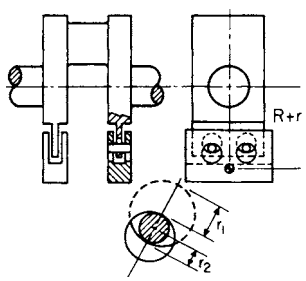

Fig. 3.4.16

Response to Periodic Excitations A problem of interest in mechanical vibrations concerns the response $x(t)$ of the cam and follower system shown in Fig. 3.4.17. As the cam rotates at a constant angular rate, the follower undergoes the periodic displacement $y(t)$, where $y(t)$ has the period T. The equation of motion is

$$m\ddot{x} + (k_1 + k_2)x = k_2 y \tag{3.4.51}$$

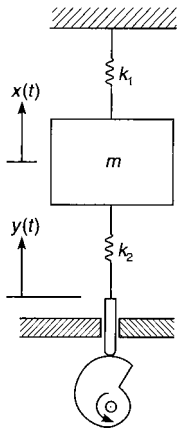

Fig. 3.4.17

Any periodic function can be expanded in a series of harmonic components in the form of the Fourier series

$$y(t) = \frac{1}{2}a_0 + \sum_{p=1}^{\infty}(a_p \cos \omega_0 t + b_p \sin p\omega_0 t) \quad \omega_0 = 2\pi/T \tag{3.4.52}$$

where ω_0 is called the **fundamental harmonic** and $p\omega_0$ ($p = 1, 2, \ldots$) are called **higher harmonics,** in which p is an integer. The coefficients have the expressions

$$\begin{aligned} a_p &= \frac{2}{T}\int_0^T y(t)\cos p\omega_0 t \qquad p = 0, 1, 2, \ldots \\ b_p &= \frac{2}{T}\int_0^T y(t)\sin p\omega_0 t \qquad p = 1, 2, \ldots \end{aligned} \tag{3.4.53}$$

Note that the limits of integration can be changed, as long as the integration covers one complete period. From Eq. (3.4.27), and a companion equation for the sine counterpart, the response is

$$x(t) = \frac{k_2}{k_1 + k_2}\left[\frac{1}{2}a_0 + \sum_{p=1}^{\infty}\frac{1}{1 - (p\omega_0/\omega_n)^2} \times (a_p \cos p\omega_0 t + b_p \sin p\omega_0 t)\right] \tag{3.4.54}$$

where

$$\omega_n = \sqrt{(k_1 + k_2)/m} \tag{3.4.55}$$

is the natural frequency of the system. Equation (3.5.54) describes a steady-state response, so that a description in terms of time is not very informative. More significant information can be extracted by plotting the amplitudes of the harmonic components versus the harmonic number. Such plots are called **frequency spectra,** and there is one for the excitation and one for the response. Equation (3.4.54) leads to the conclusion that **resonance occurs for** $p\omega_0 = \omega_n$.

As an example, consider the periodic excitation shown in Fig. 3.4.18 and use Eqs. (3.4.53) to obtain the coefficients

$$a_0 = 2A,\ a_p = 0,\ b_p = \begin{cases} 4B/p\pi & p \text{ odd} \\ 0 & p \text{ even} \end{cases} \tag{3.4.56}$$

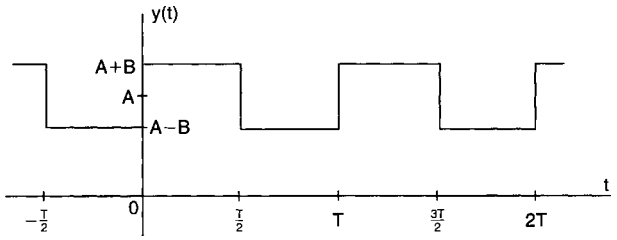

Fig. 3.4.18 Example of periodic excitation.

The excitation and response frequency spectra are displayed in Figs. 3.4.19*a* and *b*, the latter for the case in which $\omega_n = 4\omega_0$.

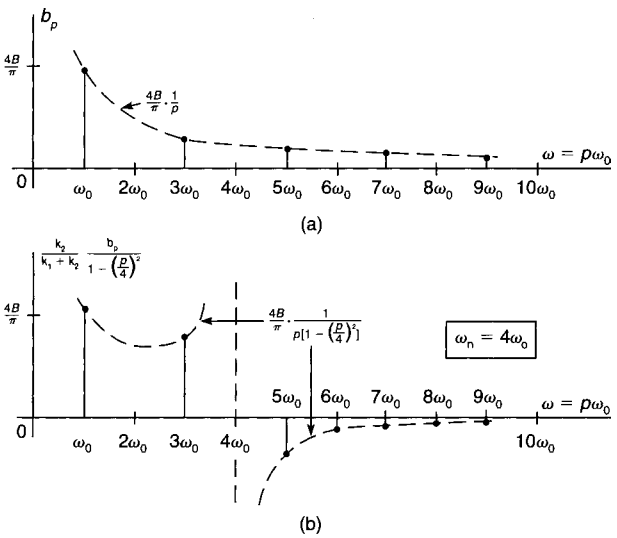

Fig. 3.4.19 (*a*) Excitation frequency spectrum; (*b*) response frequency spectrum for the periodic excitation of Fig. 3.4.18.

Unit Impulse and Impulse Response Harmonic and periodic forces represent **steady-state excitations;** they **persist indefinitely.** The response to such forces is also steady state. An entirely different class of forces consists of **arbitrary,** or **transient, forces.** The term *transient* is not entirely appropriate, as some of these forces can also persist indefinitely. Concepts pivotal to the response to arbitrary forces are the unit impulse and the impulse response. The **unit impulse,** denoted by $\delta(t - a)$, represents a function of very high amplitude and defined over a very small time interval at $t = a$ such that the area enclosed is equal to 1 (Fig. 3.4.20). The **impulse response,** denoted by $g(t)$, is defined as the response of a system to a unit impulse applied at $t = 0$, with the initial conditions being equal to zero. For the mass-damper-spring system of Fig. 3.4.2, the impulse response is

$$g(t) = \frac{1}{m\omega_d} e^{-\zeta\omega_n t} \sin \omega_d t \qquad t > 0 \tag{3.4.57}$$

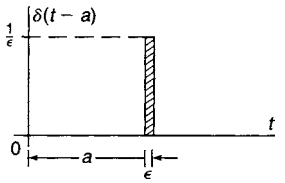

Fig. 3.4.20

Convolution Integral An arbitrary force $F(t)$ as shown in Fig. 3.4.21 can be regarded as a superposition of impulses of magnitude $F(\tau)d\tau$ and applied at $t = \tau$. Hence, the response to an arbitrary force can be regarded as a superposition of impulse responses $g(t - \tau)$ of magnitude $F(\tau)d\tau$, or

$$\begin{aligned} x(t) &= \int_0^t F(\tau)g(t-\tau)\,d\tau \\ &= \frac{1}{m\omega_d}\int_0^t F(\tau)e^{-\zeta\omega_n(t-\tau)} \sin \omega_d(t-\tau)\,d\tau \end{aligned} \tag{3.4.58a}$$

which is called the **convolution integral** or the **superposition integral;** it can also be written in the form

$$\begin{aligned} x(t) &= \int_0^t F(t-\tau)g(\tau)d\tau \\ &= \frac{1}{m\omega_d}\int_0^t F(t-\tau)e^{-\zeta\omega_n\tau} \sin \omega_d\tau\,d\tau \end{aligned} \tag{3.4.58b}$$

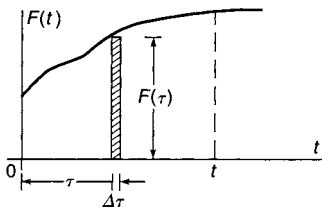

Fig. 3.4.21

Shock Spectrum Many systems are subjected on occasions to large forces applied suddenly and over periods of time that are short compared to the natural period. Such forces are capable of inflicting serious damage on a system and are referred to as **shocks.** The severity of a shock is commonly measured in terms of the maximum value of the response of a mass-spring system. The plot of the peak response versus the natural frequency is called the **shock spectrum** or **response spectrum.**

A shock $F(t)$ is characterized by its maximum value F_0, its duration T, and its shape. It is common to approximate the force by the half-sine pulse

$$F(t) = \begin{cases} F_0 \sin \omega t & \text{for } 0 < t < T = \pi/\omega \\ 0 & \text{for } t < 0 \text{ and } t > T \end{cases} \tag{3.4.59}$$

Using the convolution integral, Eq. (3.4.58b) with $\zeta = 0$, the response of a mass-spring system *during the duration of the pulse* is

$$x(t) = \frac{F_0}{k[1 - (\omega/\omega_n)^2]}\left(\sin \omega t - \frac{\omega}{\omega_n} \sin \omega_n t\right)$$

$$0 < t < \pi/\omega \tag{3.4.60}$$

The maximum response is obtained when $\dot{x} = 0$ and has the value

$$x_{\max} = \frac{F_0}{k(1 - \omega/\omega_n)} \sin \frac{2i\pi}{1 + \omega_n/\omega}$$

$$i = 1, 2, \ldots ; i < \frac{1}{2}\left(1 + \frac{\omega_n}{\omega}\right) \qquad (3.4.61)$$

On the other hand, the response *after the termination of the pulse* is

$$x(t) = \frac{F_0\omega_n^2/\omega}{k[1 - (\omega_n/\omega)^2]} [\cos \omega_n t + \cos \omega_n (t - T)] \qquad (3.4.62)$$

which has the maximum value

$$x_{\max} = \frac{2F_0\omega_n/\omega}{k[1 - (\omega_n/\omega)^2]} \cos \frac{\pi\omega_n}{2\omega} \qquad (3.4.63)$$

The shock spectrum is the plot $x_{\max}$ versus ω_n/ω. For $\omega_n < \omega$, the maximum response is given by Eq. (3.4.63) and for $\omega_n > \omega$ by Eq. (3.4.61). The shock spectrum is shown in Fig. 3.4.22 in the form of the nondimensional plot $x_{\max}k/F_0$ versus ω_n/ω.

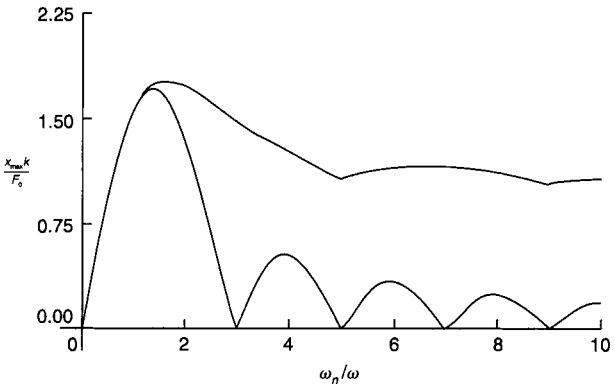

Fig. 3.4.22

MULTI-DEGREE-OF-FREEDOM SYSTEMS

Equations of Motion Many vibrating systems require more elaborate models than a single-degree-of-freedom system, such as the **multi-degree-of-freedom system** shown in Fig. 3.4.23. By using Newton's second law for each of the n masses m_i ($i = 1, 2, \ldots, n$), the equations of motion can be written in the form

$$m_i\ddot{x}_i(t) + \sum_{j=1}^{n} c_{ij}\dot{x}_j(t) + \sum_{j=1}^{n} k_{ij}x_j(t) = F_i(t)$$

$$i = 1, 2, \ldots, n \qquad (3.4.64)$$

where $x_i(t)$ is the displacement of mass m_i, $F_i(t)$ is the force acting on m_i, and c_{ij} and k_{ij} are **damping** and **stiffness coefficients,** respectively. The matrix form of Eqs. (3.4.64) is

$$M\ddot{\mathbf{x}}(t) + C\dot{\mathbf{x}}(t) + K\mathbf{x}(t) = \mathbf{F}(t) \qquad (3.4.65)$$

in which $\mathbf{x}(t)$ is the n-dimensional displacement vector, $\mathbf{F}(t)$ the corresponding force vector, M the **mass matrix,** C the **damping matrix,** and K the **stiffness matrix,** all three symmetric matrices. (In the present case the mass matrix is diagonal, but in general it is not, although it is symmetric.)

Response of Undamped Systems to Harmonic Excitations Let the harmonic excitation have the form

$$\mathbf{F}(t) = \mathbf{F}_0 \sin \omega t \qquad (3.4.66)$$

where $\mathbf{F}_0$ is a constant vector and ω is the excitation, or driving frequency. The response to the harmonic excitation is a **steady-state** response and can be expressed as

$$\mathbf{x}(t) = Z^{-1}(\omega)\mathbf{F}_0 \sin \omega t \qquad (3.4.67)$$

where $Z^{-1}(\omega)$ is the inverse of the **impedance matrix** $Z(\omega)$. In the absence of damping, the impedance matrix is

$$Z(\omega) = K - \omega^2 M \qquad (3.4.68)$$

Undamped Vibration Absorbers When a mass-spring system m_1, k_1 is subjected to a harmonic force with the frequency equal to the natural frequency, resonance occurs. In this case, it is possible to add a second mass-spring system m_2, k_2 so designed as to produce a two-degree-of-freedom system with the response of m_1 equal to zero. We refer to m_1, k_1 as the **main system** and to m_2, k_2 as the **vibration absorber.** The resulting two-degree-of-freedom system is shown in Fig. 3.4.24 and has the impedance matrix

$$Z(\omega)\begin{bmatrix} k_1 + k_2 - \omega^2 m_1 & -k_2 \\ -k_2 & k_2 - \omega^2 m_2 \end{bmatrix} \qquad (3.4.69)$$

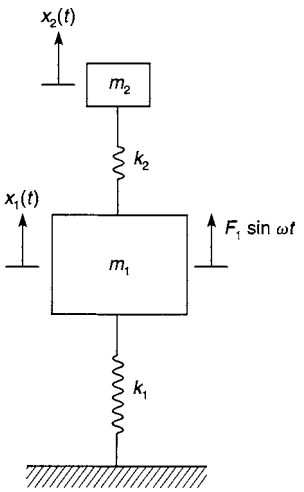

Fig. 3.4.24

Inserting Eq. (3.4.69) into Eq. (3.4.67), together with $F_1(t) = F_1 \sin \omega t$, $F_2(t) = 0$, write the steady-state response in the form

$$x_1(t) = X_1(\omega) \sin \omega t \qquad (3.4.70a)$$

$$x_2(t) = X_2(\omega) \sin \omega t \qquad (3.4.70b)$$

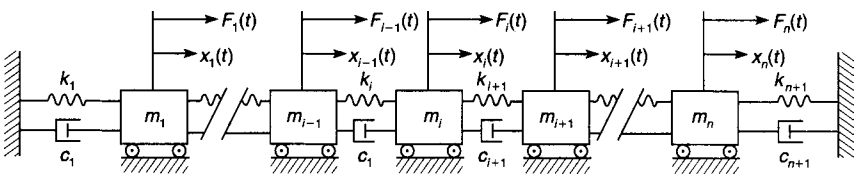

Fig. 3.4.23

where the amplitudes are given by

$$X_1(\omega) = \frac{[1 - (\omega/\omega_a)^2]x_{st}}{[1 + \mu(\omega_a/\omega_n)^2 - (\omega/\omega_n)^2][1 - (\omega/\omega_a)^2] - \mu(\omega_a/\omega_n)^2} \tag{3.4.71a}$$

$$X_2(\omega) = \frac{x_{st}}{[1 + \mu(\omega_a/\omega_n)^2 - (\omega/\omega_n)^2][1 - (\omega/\omega_a)^2] - \mu(\omega_a/\omega_n)^2} \tag{3.4.71b}$$

in which

$\omega_n = \sqrt{k_1/m_1}$ = the natural frequency of the main system alone
$\omega_a = \sqrt{k_2/m_2}$ = the natural frequency of the absorber alone
$x_{st} = F_1/k_1$ = the static deflection of the main system
$\mu = m_2/m_1$ = the ratio of the absorber mass to the main mass

From Eqs. (3.4.70*a*) and (3.4.71*a*), we conclude that if we choose m_2 and k_2 such that $\omega_a = \omega$, the response $x_1(t)$ of the main mass is zero. Moreover, from Eqs. (3.4.70*b*) and (3.4.71*b*),

$$x_2(t) = -\left(\frac{\omega_n}{\omega_a}\right)^2 \frac{x_{st}}{\mu} \sin \omega t = -\frac{F_1}{k_2} \sin \omega t \tag{3.4.72}$$

so that the force in the absorber spring is

$$k_2 x_2(t) = -F_1 \sin \omega t \tag{3.4.73}$$

Hence, *the absorber exerts a force on the main mass balancing exactly the applied force* $F_1 \sin \omega t$.

A vibration absorber designed for a given operating frequency ω can perform satisfactorily for operating frequencies that vary slightly from ω. In this case, the motion of m_1 is not zero, but its amplitude tends to be very small, as can be verified from a frequency response plot $X_1(\omega)/x_{st}$ versus ω/ω_n; Fig. 3.4.25 shows such a plot for $\mu = 0.2$ and $\omega_n = \omega_a$. The shaded area indicates the range in which the performance can be regarded as satisfactory. Note that the thin line in Fig. 3.4.25 represents the frequency response of the main system alone. Also note that the system resulting from the combination of the main system and the absorber has two resonance frequencies, but they are removed from the operating frequency $\omega = \omega_n = \omega_a$.

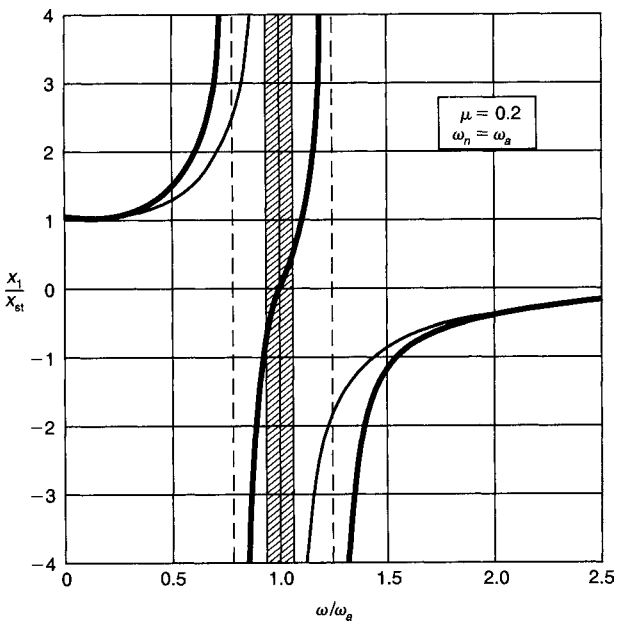

Fig. 3.4.25

Natural Modes of Vibration In the absence of damping and external forces, Eq. (3.4.65) reduces to the free-vibration equation

$$M\ddot{\mathbf{x}}(t) + K\mathbf{x}(t) = \mathbf{0} \tag{3.4.74}$$

which has the harmonic solution

$$\mathbf{x}(t) = \mathbf{u} \cos(\omega t - \phi) \tag{3.4.75}$$

where $\mathbf{u}$ is a constant vector, ω a frequency of oscillation, and ϕ a phase angle. Introduction of Eq. (3.4.75) into Eq. (3.4.74) and division through by $\cos(\omega t - \phi)$ results in

$$K\mathbf{u} = \omega^2 M\mathbf{u} \tag{3.4.76}$$

which represents a set of n simultaneous algebraic equations known as the **eigenvalue problem.** It has n solutions consisting of the **eigenvalues** ω_r^2; the square roots represent the **natural frequencies** ω_r ($r = 1, 2, \ldots, n$). Moreover, to each natural frequency ω_r there corresponds a vector $\mathbf{u}_r$ ($r = 1, 2, \ldots, n$) called **eigenvector,** or **modal vector,** or **natural mode.** The modal vectors possess the **orthogonality property,** or

$$\mathbf{u}_s^T M\mathbf{u}_r = 0 \tag{3.4.77a}$$
$$\mathbf{u}_s^T K\mathbf{u}_r = 0 \tag{3.4.77b}$$

(for $r, s = 1, 2, \ldots, n$; $r \neq s$), in which $\mathbf{u}_s^T$ is the **transpose** of $\mathbf{u}_s$, a row vector. It is convenient to adjust the magnitude of the modal vectors so as to satisfy

$$\mathbf{u}_r^T M\mathbf{u}_r = 1 \tag{3.4.78a}$$
$$\mathbf{u}_r^T K\mathbf{u}_r = \omega_r^2 \tag{3.4.78b}$$

(for $r = 1, 2, \ldots, n$), a process known as normalization, in which case $\mathbf{u}_r$ are called **normal modes.** Note that the normalization process involves Eq. (3.4.78*a*) alone, as Eq. (3.4.78*b*) follows automatically. The solution of the eigenvalue problem can be obtained by a large variety of computational algorithms (Meirovitch, "Principles and Techniques of Vibrations," Prentice-Hall). Commercially, they are available in software packages for numerical computations, such as MATLAB.

The actual solution of Eq. (3.4.74) is obtained below in the context of the transient response.

Transient Response of Undamped Systems From Eq. (3.4.65), the vibration of undamped systems satisfies the equation

$$M\ddot{\mathbf{x}}(t) + K\mathbf{x}(t) = \mathbf{F}(t) \tag{3.4.79}$$

where $\mathbf{F}(t)$ is an arbitrary force vector. In addition, the displacement and velocity vectors must satisfy the initial conditions $\mathbf{x}(0) = \mathbf{x}_0$, $\dot{\mathbf{x}}(0) = \mathbf{v}_0$. The solution of Eq. (3.4.79) has the form

$$\mathbf{x}(t) = \sum_{r=1}^{n} \mathbf{u}_r q_r(t) \tag{3.4.80}$$

in which $\mathbf{u}_r$ are the modal vectors and $\mathbf{q}_r(t)$ are associated **modal coordinates.** Inserting Eq. (3.4.80) into Eq. (3.4.79), premultiplying the result by $\mathbf{u}_s^T$, and using Eqs. (3.4.77) and (3.4.78) we obtain the modal equations

$$\ddot{q}_r(t) + \omega_r^2 q_r(t) = Q_r(t) \qquad r = 1, 2, \ldots, n \tag{3.4.81}$$

where

$$Q_r(t) = \mathbf{u}_r^T \mathbf{F}(t) \qquad r = 1, 2, \ldots, n \tag{3.4.82}$$

are **modal forces.** Equations (3.4.81) resemble the equation of a single-degree-of-freedom system and have the solution

$$q_r(t) = \frac{1}{\omega_r}\int_0^t Q_r(t - \tau) \sin \omega_r \tau \, d\tau + q_r(0) \cos \omega_r t + \frac{\dot{q}_r(0)}{\omega_r} \sin \omega_r t \qquad r = 1, 2, \ldots, n \tag{3.4.83}$$

where

$$q_r(0) = \mathbf{u}_r^T M\mathbf{x}_0 \tag{3.4.84a}$$
$$\dot{q}_r(0) = \mathbf{u}_r^T M\mathbf{v}_0 \tag{3.4.84b}$$

(for $r = 1, 2, \ldots, n$) are **initial modal displacements and velocities,**

respectively. The solution to both external forces and initial excitations is obtained by inserting Eqs. (3.4.83) into Eq. (3.4.80).

Systems with Proportional Damping When the system is damped, the response does not in general have the form of Eq. (3.4.80), and a more involved approach is necessary (Meirovitch, "Fundamentals of Vibration," McGraw-Hill). In the special case in which the damping matrix C is proportional to the mass matrix M or the stiffness matrix K, or is a linear combination of M and K, the preceding approach yields the modal equations

$$\ddot{q}_r(t) + 2\zeta_r\omega_r\dot{q}_r(t) + \omega_r^2 q_r(t) = Q_r(t) \qquad r = 1, 2, \ldots, n \tag{3.4.85}$$

where ζ_r are **modal damping factors.** Equations (3.4.85) have the solution

$$q_r(t) = \frac{1}{\omega_{dr}}\int_0^t Q_r(t-\tau)e^{-\zeta_r\omega_r\tau}\sin\omega_{dr}\tau\,d\tau + \frac{q_r(0)}{\sqrt{1-\zeta_r^2}}e^{-\zeta_r\omega_r t}\cos(\omega_{dr}t - \psi_r) + \frac{\dot{q}_r(0)}{\omega_{dr}}\sin\omega_{dr}t \qquad r = 1, 2, \ldots, n \tag{3.4.86}$$

in which

$$\omega_{dr} = \omega_r\sqrt{1-\zeta_r^2} \qquad r = 1, 2, \ldots, n \tag{3.4.87}$$

is the damped frequency in the rth mode and

$$\psi_r = \tan^{-1}\frac{\zeta_r}{\sqrt{1-\zeta_r^2}} \qquad r = 1, 2, \ldots, n \tag{3.4.88}$$

is a phase angle associated with the rth mode. The quantities $Q_r(t)$, $q_r(0)$, and $\dot{q}_r(0)$ remain as defined by Eqs. (3.4.82), (3.4.84a), and (3.4.84b), respectively.

DISTRIBUTED-PARAMETER SYSTEMS

Vibration of Rods, Shafts, and Strings The axial vibration of rods is described by the equation

$$-\frac{\partial}{\partial x}\left[EA(x)\frac{\partial u(x,t)}{\partial x}\right] + m(x)\frac{\partial^2 u(x,t)}{\partial t^2} = f(x,t) \qquad 0 < x < L \tag{3.4.89}$$

where $u(x, t)$ is the axial displacement, $f(x, t)$ the axial force per unit length, E the modulus of elasticity, $A(x)$ the cross-sectional area, and $m(x)$ the mass per unit length. The solution $u(x, t)$ is subject to one boundary condition at each end.

Before attempting to solve Eq. (3.4.89), consider the free vibration problem, $f(x, t) = 0$. The solution of the latter problem is harmonic and can be expressed as

$$u(x,t) = U(x)\cos(\omega t - \phi) \tag{3.4.90}$$

where $U(x)$ is the amplitude, ω the frequency, and ϕ an inconsequential phase angle. Inserting Eq. (3.4.90) into Eq. (3.4.89) with $f(x, t) = 0$ and dividing through by $\cos(\omega t - \phi)$, we conclude that $U(x)$ and ω must satisfy the *eigenvalue problem*

$$-\frac{d}{dx}\left[EA(x)\frac{dU(x)}{dx}\right] = \omega^2 m(x)U(x) \qquad 0 < x < L \tag{3.4.91}$$

where $U(x)$ must satisfy one boundary condition at each end. At a fixed end the displacement U must be zero and at a free end the axial force $EA\,dU/dx$ is zero.

Exact solutions of the eigenvalue problem are possible in only a few cases, mostly for uniform rods, in which case Eq. (3.4.91) reduces to

$$\frac{d^2U(x)}{dx^2} + \beta^2 U(x) = 0 \qquad \beta^2 = \frac{\omega^2 m}{EA} \qquad 0 < x < L \tag{3.4.92}$$

whose solution is

$$U(x) = A\sin\beta x + B\cos\beta x \tag{3.4.93}$$

where A and B are constants of integration, determined from specified boundary conditions. In the case of a **fixed-free** rod, the boundary conditions are

$$U(0) = 0 \tag{3.4.94a}$$

$$EA\left.\frac{dU}{dx}\right|_{x=L} = 0 \tag{3.4.94b}$$

Condition (3.4.94a) gives $B = 0$ and condition (3.4.94b) yields the **characteristic equation**

$$\cos\beta L = 0 \tag{3.4.95}$$

which has the infinity of solutions

$$\beta_r L = \frac{(2r-1)\pi}{2} \qquad r = 1, 2, \ldots \tag{3.4.96}$$

where β_r represent the *eigenvalues;* they are related to the *natural frequencies* ω_r by

$$\omega_r = \beta_r\sqrt{\frac{EA}{m}} = \frac{(2r-1)\pi}{2}\sqrt{\frac{EA}{mL^2}} \qquad r = 1, 2, \ldots \tag{3.4.97}$$

From Eq. (3.4.93), the **normal modes** are

$$U_r(x) = \sqrt{\frac{2}{mL}}\sin\frac{(2r-1)\pi x}{2L} \qquad r = 1, 2, \ldots \tag{3.4.98}$$

For a **fixed-fixed** rod, the natural frequencies and normal modes are

$$\omega_r = r\pi\sqrt{\frac{EA}{mL^2}} \qquad U_r(x) = \sqrt{\frac{2}{mL}}\sin\frac{r\pi x}{L} \qquad r = 1, 2, \ldots \tag{3.4.99}$$

and for a **free-free** rod they are

$$\omega_0 = 0 \qquad U_0 = \sqrt{\frac{1}{mL}} \tag{3.4.100a}$$

$$\omega_r = r\pi\sqrt{\frac{EA}{mL^2}} \qquad U_r(x) = \sqrt{\frac{2}{mL}}\cos\frac{r\pi x}{L} \qquad r = 1, 2, \ldots \tag{3.4.100b}$$

Note that U_0 represents a **rigid-body mode,** with zero natural frequency.

In every case the modes are orthogonal, satisfying the conditions

$$\int_0^L mU_s(x)U_r(x)\,dx = 0 \tag{3.4.101a}$$

$$-\int_0^L U_s(x)\frac{d}{dx}\left[EA\frac{dU_r(x)}{dx}\right]dx = 0 \tag{3.4.101b}$$

(for $r, s = 0, 1, 2, \ldots, r \neq s$) and have been normalized to satisfy the relations

$$\int_0^L mU_r^2(x)\,dx = 1 \tag{3.4.102a}$$

$$-\int_0^L U_r(x)\frac{d}{dx}\left[EA\frac{dU_r(x)}{dx}\right]dx = \omega_r^2 \tag{3.4.102b}$$

(for $r = 0, 1, 2, \ldots$). Note that the orthogonality of the normal modes extends to the rigid-body mode.

The response of the rod has the form

$$u(x,t) = \sum_{r=1}^{\infty} U_r(x)q_r(t) \tag{3.4.103}$$

Introducing Eq. (3.4.103) into Eq. (3.4.89), multiplying through by $U_s(x)$, integrating over the length of the rod, and using Eqs. (3.4.101) and (3.4.102) we obtain the **modal equations**

$$\ddot{q}_r(t) + \omega_r^2 q_r(t) = Q_r(t) \qquad r = 1, 2, \ldots \tag{3.4.104}$$

where

$$Q_r(t) = \int_0^L U_r(x)f(x,t)\,dx \qquad r = 1, 2, \ldots \tag{3.4.105}$$

Table 3.4.4 Analogous Quantities for Rods, Shafts, and Strings

	Rods	Shafts	Strings
Displacement	Axial—$u(x, t)$	Torsional—$\theta(x, t)$	Transverse—$w(x, t)$
Inertia (per unit length)	Mass—$m(x)$	Mass polar moment of inertia—$I(x)$	Mass—$\rho(x)$
Stiffness	Axial—$EA(x)$ E = Young's modulus $A(x)$ = cross-sectional area	Torsional—$GJ(x)$ G = shear modulus $J(x)$ = area polar moment of inertia	Tension—$T(x)$
Load (per unit length)	Force—$f(x, t)$	Moment—$m(x, t)$	Force—$f(x, t)$

are the **modal forces.** Equations (3.4.104) resemble Eqs. (3.4.81) entirely; their solution is given by Eqs. (3.4.83). The displacement of the rod is obtained by inserting Eqs. (3.4.83) into Eq. (3.4.103).

As an example, consider the response of a uniform fixed-free rod to the uniformly distributed impulsive force

$$f(x, t) = \hat{f}_0 \delta(t) \tag{3.4.106}$$

Inserting Eqs. (3.4.98) and (3.4.106) into Eq. (3.4.105), we obtain the modal forces

$$Q_r(t) = \sqrt{\frac{2}{mL}} \int_0^L \sin \frac{(2r-1)\pi x}{2L} \hat{f}_0 \delta(t)\, dx$$

$$= \frac{2}{(2r-1)\pi} \sqrt{\frac{2L}{m}} \hat{f}_0 \delta(t) \qquad r = 1, 2, \ldots \tag{3.4.107}$$

so that, from Eqs. (3.4.83), the modal displacements are

$$q_r(t) = \frac{1}{\omega_r} \frac{2}{(2r-1)\pi} \sqrt{\frac{2L}{m}} \hat{f}_0 \int_0^t \delta(t-\tau) \sin \omega_r \tau \, d\tau$$

$$= \left[\frac{2}{(2r-1)\pi} \right]^2 \sqrt{\frac{2L^3}{EA}} \hat{f}_0 \sin \frac{(2r-1)\pi}{2} \sqrt{\frac{EA}{mL^2}} t$$

$$r = 1, 2, \ldots \tag{3.4.108}$$

Finally, from Eq. (3.4.103), the response is

$$u(x, t) = \frac{8\hat{f}_0 L}{\pi^2} \sqrt{\frac{1}{mEA}} \sum_{r=1}^{\infty} \frac{1}{(2r-1)^2} \sin \frac{(2r-1)\pi x}{2L} \times \sin \frac{(2r-1)\pi}{2} \sqrt{\frac{EA}{mL^2}} t \tag{3.4.109}$$

The torsional vibration of shafts and the transverse vibration of strings are described by the same differential equation and boundary conditions as the axial vibration of rods, except that the nature of the displacement, inertia and stiffness parameters, and external excitations differs, as indicated in Table 3.4.4.

Bending Vibration of Beams The procedure for evaluating the response of beams in transverse vibration is similar to that for rods, the main difference arising in the stiffness term. The differential equation for beams in bending is

$$\frac{\partial^2}{\partial x^2} \left[EI(x) \frac{\partial^2 w(x, t)}{\partial x^2} \right] + m(x) \frac{\partial^2 w(x, t)}{\partial t^2} = f(x, t) \qquad 0 < x < L \tag{3.4.110}$$

in which $w(x, t)$ is the transverse displacement, $f(x, t)$ the force per unit length, $I(x)$ the cross-sectional area moment of inertia, and $m(x)$ the mass per unit length. The solution $w(x, t)$ must satisfy two boundary conditions at each end.

The eigenvalue problem is described by the differential equation

$$\frac{d^2}{dx^2} \left[EI(x) \frac{d^2 W(x)}{dx^2} \right] = \omega^2 m(x) W(x) \qquad 0 < x < L \tag{3.4.111}$$

and two boundary conditions at each end, depending on the type of support. Some possible boundary conditions are given in Table 3.4.5. The solution of the eigenvalue problem consists of the natural frequencies ω_r and natural modes $W_r(x)$ $(r = 1, 2, \ldots)$. The first five normalized natural frequencies of uniform beams with six different boundary conditions are listed in Table 3.4.6. The normal modes for the hinged-hinged beam are

$$W_r(x) = \sqrt{\frac{2}{mL}} \sin \frac{r\pi x}{L} \qquad r = 1, 2, \ldots \tag{3.4.112}$$

The normal modes for the remaining beam types are more involved and they involve both trigonometric and hyperbolic functions (Meirovitch, "Fundamentals of Vibrations"). The modes for every beam type are orthogonal and can be used to obtain the response $w(x, t)$ in the form of a series similar to Eq. (3.4.103).

Vibration of Membranes A **membrane** is a very thin sheet of material stretched over a two-dimensional domain enclosed by one or two nonintersecting boundaries. It can be regarded as the two-dimensional counterpart of the string. Like a string, it derives the ability to resist transverse displacements from tension, which acts in all directions in the plane of the membrane and at all its points. It is commonly assumed that the tension is uniform and does not change as the membrane deflects.

Table 3.4.6 Normalized Natural Frequencies for Various Beams

Beam type	$\omega_1\sqrt{mL^4/EI}$	$\omega_2\sqrt{mL^4/EI}$	$\omega_3\sqrt{mL^4/EI}$	$\omega_4\sqrt{mL^4/EI}$	$\omega_5\sqrt{mL^2/EI}$
Hinged-hinged	π^2	$4\pi^2$	$9\pi^2$	$16\pi^2$	$25\pi^2$
Clamped-free	1.875^2	4.694^2	7.855^2	10.996^2	14.137^2
Free-free	0	0	$(1.506\pi)^2$	$(2.500\pi)^2$	$(3.500\pi)^2$
Clamped—clamped	$(1.506\pi)^2$	$(2.500\pi)^2$	$(3.500\pi)^2$	$(4.500\pi)^2$	$(5.500\pi)^2$
Clamped-hinged	3.927^2	7.069^2	10.210^2	13.352^2	16.493^2
Hinged-free	0	3.927^2	7.069^2	10.210^2	13.352^2

The general procedure for calculating the response of membranes remains the same as for rods and beams, but there is one significant new factor, namely, the shape of the boundary, which dictates the type of coordinates to be used. For rectangular membranes cartesian coordinates must be used, and for circular membranes polar coordinates are indicated.

The differential equation for the transverse vibration of membranes is

$$-T\nabla^2 w + \rho\frac{\partial^2 w}{\partial t^2} = f \tag{3.4.113}$$

which must be satisfied at every interior point of the membrane, where w is the transverse displacement, f the transverse force per unit area, T the tension, and ρ the mass per unit area. Moreover, ∇^2 is the Laplacian operator, whose expression depends on the coordinates used. The solution w must satisfy one boundary condition at every boundary point. Using the established procedure, the eigenvalue problem is described by the differential equation

$$-T\nabla^2 W = \omega^2 \rho W \tag{3.4.114}$$

where W is the displacement amplitude; it must satisfy one boundary condition at every point of the boundary.

Consider a **rectangular membrane fixed** at $x = 0, a$ and $y = 0, b$, in which case the Laplacian operator in terms of the cartesian coordinates x and y has the form

$$\nabla^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \tag{3.4.115}$$

The boundary conditions are $W(0, y) = W(a, y) = W(x, 0) = W(x, b) = 0$. The natural frequencies are

$$\omega_{mn} = \pi\sqrt{\left[\left(\frac{m}{a}\right)^2 + \left(\frac{n}{b}\right)^2\right]\frac{T}{\rho}} \qquad m, n = 1, 2, \ldots \tag{3.4.116}$$

and the normal modes are

$$W_{mn}(x, y) = \frac{2}{\sqrt{\rho ab}}\sin\frac{m\pi x}{a}\sin\frac{n\pi y}{b} \qquad m, n = 1, 2, \ldots \tag{3.4.117}$$

The modes satisfy the orthogonality conditions

$$\int_0^a\int_0^b \rho W_{mn}(x, y)W_{rs}(x, y)\,dx\,dy = 0, \qquad m \neq r \text{ and/or } n \neq s \tag{3.4.118a}$$

$$-\int_0^a\int_0^b W_{mn}(x, y)T\nabla^2 W_{rs}(x, y)\,dx\,dy = 0, \qquad m \neq r \text{ and/or } n \neq s \tag{3.4.118b}$$

and have been normalized so that $\int_0^a\int_0^b \rho W_{mn}^2(x, y)\,dx\,dy = 1 (m, n = 1, 2, \ldots)$. Note that, because the problem is two-dimensional, it is necessary to identify the natural frequencies and modes by two subscripts. With this exception, the procedure for obtaining the response is the same as for rods and beams.

Next, consider a **uniform circular membrane fixed at** $r = a$. In this case, the Laplacian operator in terms of the polar coordinates r and θ is

$$\nabla^2 = \frac{\partial^2}{\partial r^2} + \frac{1}{r}\frac{\partial}{\partial r} + \frac{1}{r^2}\frac{\partial^2}{\partial\theta^2} \tag{3.4.119}$$

The natural modes for circular membranes are appreciably more involved than for rectangular membranes. They are products of Bessel functions of $\omega_{mn}r$ and trigonometric functions of $m\theta$, where $m = 0, 1, 2, \ldots$ and $n = 1, 2, \ldots$. The modes are given in Meirovitch, "Principles and Techniques of Vibrations," Prentice-Hall. Table 3.4.7 gives the normalized natural frequencies $\omega_{mn}^* = (\omega_{mn}/2\pi)\sqrt{\rho a^2/T}$ corresponding to $m = 0, 1, 2$ and $n = 1, 2, 3$. The modes satisfy the orthogonality relations

$$\int_0^a\int_0^{2\pi} \rho W_{mn}(r, \theta)W_{rs}(r, \theta)r\,dr\,d\theta = 0, \qquad m \neq r \text{ and/or } n \neq s \tag{3.4.120a}$$

Table 3.4.7 Circular Membrane Normalized Natural Frequencies $\omega_{mn}^* = (\omega_{mn}/2\pi)\sqrt{\rho a^2/T}$

	n		
m	1	2	3
0	0.3827	0.8786	1.3773
1	0.6099	1.1165	1.6192
2	0.8174	1.3397	1.8494

$$-\int_0^a\int_0^{2\pi} W_{mn}(r, \theta)T\nabla^2 W_{rs}(r, \theta)r\,dr\,d\theta = 0, \qquad m \neq r \text{ and/or } n \neq s \tag{3.4.120b}$$

The response of circular membranes is obtained in the usual manner.

Bending Vibration of Plates Consider **plates** whose behavior is governed by the elementary plate theory, which is based on the following assumptions: (1) deflections are small compared to the plate thickness; (2) the normal stresses in the direction transverse to the plate are negligible; (3) there is no force resultant on the cross-sectional area of a plate differential element: the middle plane of the plate does not undergo deformations and represents a neutral plane, and (4) any straight line normal to the middle plane remains so during bending. Under these assumptions, the differential equation for the bending vibration of plates is

$$D\nabla^4 w + m\frac{\partial^2 w}{\partial t^2} = f \tag{3.4.121}$$

and is to be satisfied at every interior point of the plate, where w is the transverse displacement, f the transverse force per unit area, m the mass per unit area, $D = Eh^3/12(1 - \nu^2)$ the plate flexural rigidity, E Young's modulus, h the plate thickness, and ν Poisson's ratio. Moreover, ∇^4 is the biharmonic operator. The solution w must satisfy two boundary conditions at every point of the boundary. The eigenvalue problem is defined by the differential equation

$$D\nabla^4 W = \omega^2 mW \tag{3.4.122}$$

and corresponding boundary conditions.

Consider a **rectangular plate simply supported** at $x = 0, a$ and $y = 0, b$. Because of the shape of the plate, we must use cartesian coordinates, in which case the biharmonic operator has the expression

$$\nabla^4 = \nabla^2\nabla^2 = \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}\right)\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}\right) = \frac{\partial^4}{\partial x^4} + 2\frac{\partial^4}{\partial x^2\partial y^2} + \frac{\partial^4}{\partial y^4} \tag{3.4.123}$$

Moreover, the boundary conditions are $W = 0$ and $\partial^2 W/\partial x^2 = 0$ for $x = 0, a$ and $W = 0$ and $\partial^2 W/\partial y^2 = 0$ for $y = 0, b$. The natural frequencies are

$$\omega_{mn} = \pi^2\left[\left(\frac{m}{a}\right)^2 + \left(\frac{n}{b}\right)^2\right]\sqrt{\frac{D}{m}} \qquad m, n = 1, 2, \ldots \tag{3.4.124}$$

and no confusion should arise because the same symbol is used for one of the subscripts and for the mass per unit area. The corresponding normal modes are

$$W_{mn}(x, y) = \frac{2}{\sqrt{mab}}\sin\frac{m\pi x}{n}\sin\frac{n\pi y}{b} \qquad m, n = 1, 2, \ldots \tag{3.4.125}$$

and they are recognized as being the same as for rectangular membranes fixed at all boundaries.

A **circular plate** requires use of polar coordinates, so that the biharmonic operator has the form

$$\nabla^4 = \nabla^2\nabla^2 = \left(\frac{\partial^2}{\partial r^2} + \frac{1}{r}\frac{\partial}{\partial r} + \frac{1}{r^2}\frac{\partial^2}{\partial\theta^2}\right)\left(\frac{\partial^2}{\partial r^2} + \frac{1}{r}\frac{\partial}{\partial r} + \frac{1}{r^2}\frac{\partial^2}{\partial\theta^2}\right) \tag{3.4.126}$$

Table 3.4.8 Circular Plate Normalized Natural Frequencies $\omega^*_{mn} = \omega_{mn}(a/\pi)^2\sqrt{m/D}$

	n		
m	1	2	3
0	1.015^2	2.007^2	3.000^2
1	1.468^2	2.483^2	3.490^2
2	1.879^2	2.992^2	4.000^2

Consider a **plate clamped** at $r = a$, in which case the boundary conditions are $W(r, \theta) = 0$ and $\partial W(r, \theta)/\partial r = 0$ at $r = a$. In addition, the solution must be finite at every interior point in the plate, and in particular at $r = 0$. The natural modes have involved expressions; they are given in Meirovitch, "Principles and Techniques of Vibrations," Prentice-Hall. Table 3.4.8 lists the normalized natural frequencies $\omega^*_{mn} = \omega_{mn}(a/\pi)^2\sqrt{m/D}$ corresponding to $m = 0, 1, 2$ and $n = 1, 2, 3$.

The natural modes of the plates are orthogonal and can be used to obtain the response to both initial and external excitations.

APPROXIMATE METHODS FOR DISTRIBUTED SYSTEMS

Rayleigh's Energy Method The eigenvalue problem contains vital information concerning vibrating systems, namely, the natural frequencies and modes. In the majority of practical cases, exact solutions to the eigenvalue problem for distributed systems are not possible, so that the interest lies in **approximate solutions.** This is often the case when the mass and stiffness are distributed nonuniformly and/or the boundary conditions cannot be satisfied, the latter in particular for two-dimensional systems with irregularly shaped boundaries.

When the objective is to estimate the lowest natural frequency, Rayleigh's energy method has few equals. As discussed earlier, free vibration of undamped systems is harmonic and can be expressed as

$$w(x, t) = W(x)\cos(\omega t - \phi) \tag{3.4.127}$$

where $W(x)$ is the displacement amplitude, ω the free vibration frequency, and ϕ an inconsequential phase angle. The kinetic energy represents an integral involving the velocity squared. Hence, using Eq. (3.4.127), the kinetic energy can be written in the form

$$T(t) = \frac{1}{2}\int_0^L m(x)\left[\frac{\partial w(x, t)}{\partial t}\right]^2 dx = \omega^2 T_{\text{ref}}\sin^2(\omega t - \phi) \tag{3.4.128}$$

where

$$T_{\text{ref}} = \frac{1}{2}\int_0^L m(x)W^2(x)\,dx \tag{3.4.129}$$

is called the **reference kinetic energy.** The form of the potential energy is system-dependent, but in general is an integral involving the square of the displacement and of its derivatives with respect to the spatial coordinates (see Table 3.4.9). It can be expressed as

$$V(t) = V_{\max}\cos^2(\omega t - \phi) \tag{3.4.130}$$

where $V_{\max}$ is the maximum potential energy, which can be obtained by simply replacing $w(x, t)$ by $W(x)$ in $V(t)$. Using the principle of conservation of energy in conjunction with Eqs. (3.4.128) and (3.4.130), we can write

$$E = T + V = T_{\max} + 0 = 0 + V_{\max} \tag{3.4.131}$$

in which

$$T_{\max} = \omega^2 T_{\text{ref}} \tag{3.4.132}$$

It follows that

$$\omega^2 = \frac{V_{\max}}{T_{\text{ref}}} \tag{3.4.133}$$

Equation (3.4.133) represents **Rayleigh's quotient,** which has the remarkable property that it has a minimum value for $W(x) = W_1(x)$, the minimum value being ω_1^2. Rayleigh's energy method amounts to selecting a trial function $W(x)$ reasonably close to the lowest natural mode $W_1(x)$, inserting this function into Rayleigh's quotient, and carrying out the indicated integrations. Then, ω^2 will be one order of magnitude closer to the lowest eigenvalue ω_1^2 than $W(x)$ is to $W_1(x)$, thus providing a good estimate ω of the lowest natural frequency ω_1. Quite often, the static deformation of the system acted on by loads proportional to the mass distribution is a good choice. In some cases, the lowest mode of a related simpler system can yield good results.

As an example, estimate the lowest natural frequency of a uniform bar in axial vibration with a mass M attached at $x = L$ (Fig. 3.4.26) for the three trial functions (1) $U(x) = x/L$; (2) $U(x) = (1 + M/mL)(x/L) - (x/L)^2/2$, representing the static deformation; and (3) $U(x) = \sin \pi x/2L$, representing the lowest mode of the bar without the mass M. The Rayleigh quotient for this bar is

$$\omega^2 = \frac{\displaystyle\int_0^L EA(x)[dU(x)/dx]^2\,dx}{\displaystyle\int_0^L m(x)U^2(x)\,dx + MU^2(L)} \tag{3.4.134}$$

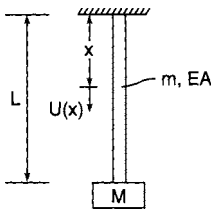

Fig. 3.4.26

The results are:

1. $$\omega^2 = \frac{\displaystyle\int_0^L EA(1/L)^2\,dx}{\displaystyle\int_0^L m(x/L)^2\,dx + M} = \frac{EA}{(M + mL/3)L}$$

2. $$\frac{\displaystyle\int_0^L EA(1 + M/mL - x/L)^2(1/L)^2\,dx}{\displaystyle\int_0^L m[(1 + M/mL)(x/L) - (x/L)^2/2]^2\,dx + M(1 + 2M/mL)^2/4}$$

$$= \frac{\left(\dfrac{M}{mL}\right)^2 + \dfrac{M}{mL} + \dfrac{1}{3}}{\dfrac{1}{3}\left(\dfrac{M}{mL}\right)^2 + \dfrac{5}{12}\dfrac{M}{mL} + \dfrac{2}{15} + \dfrac{M}{mL}\left(\dfrac{1}{2} + \dfrac{M}{mL}\right)^2}\frac{EA}{mL^2} \tag{3.4.135}$$

3. $$\omega^2 = \frac{\displaystyle\int_0^L EA\left(\frac{\pi}{2L}\right)^2\cos^2\frac{\pi x}{2L}\,dx}{\displaystyle\int_0^L m\sin^2\frac{\pi x}{2L}\,dx + M} = \frac{\pi^2}{8\left(\dfrac{1}{2} + \dfrac{M}{mL}\right)}\frac{EA}{mL^2}$$

Table 3.4.9 Potential Energy for Various Systems

System	Potential energy* $V(t)$
Rods (also shafts and strings)	$\frac{1}{2}\int_0^L EA(x)[\partial u(x, t)/\partial x]^2 dx$
Beams	$\frac{1}{2}\int_0^L EI(x)[\partial^2 w(x, t)/\partial x^2]^2 dx$
Beams with axial force	$\frac{1}{2}\int_0^L \{EI(x)[\partial^2 w(x, t)/\partial x^2]^2 + P(x)[\partial \omega(x, t)/\partial x]^2\}\,dx$
Membranes	$\frac{1}{2}\int_{\text{Area}} T\{[\partial w(x, y, t)/\partial x]^2 + [\partial w(x, y, t)/\partial y]^2\}\,dx\,dy$
Plates	$\frac{1}{2}\int_{\text{Area}} D\{\nabla^2 w(x, y, t)^2 + 2(1 - \nu)[\partial^2 w(x, y, t)/\partial x\,\partial y]^2 - [\partial^2 w(x, y, t)/\partial x^2][\partial^2 w(x, y, t)/\partial y^2]\}dx\,dy$

*If the distributed system has a spring at the boundary point a, then add a term $kw^2(a, t)/2$.

For comparison purposes, let $M = mL$, which yields the following estimates for the lowest natural frequency:

$$\begin{aligned} &1.\quad \omega = 0.8660\sqrt{\frac{EA}{mL^2}} \\ &2.\quad \omega = 0.8629\sqrt{\frac{EA}{mL^2}} \\ &3.\quad \omega = 0.9069\sqrt{\frac{EA}{mL^2}} \end{aligned} \tag{3.4.136}$$

The best estimate is the lowest one, which corresponds to case 2, with the trial function in the form of the static displacement. Note that the estimate obtained in case 1 is also quite good. It corresponds to the first case in Table 3.4.2, representing a mass-spring system in which the mass of the spring is included.

Rayleigh-Ritz Method **Rayleigh's quotient,** Eq. (3.4.133), corresponding to any trial function $W(x)$ is always larger than the lowest eigenvalue ω_1^2, and it takes the minimum value of ω_1^2 when $W(x)$ coincides with the lowest natural mode $W_1(x)$. However, this possibility must be ruled out by virtue of the assumption that W_1 is not available. The **Rayleigh-Ritz method** is a procedure for minimizing Rayleigh's quotient by means of a sequence of approximate solutions converging to the actual solution of the eigenvalue problem. The minimizing sequence has the form

$$\begin{aligned} &W(x) = a_1\phi_1(x) \\ &W(x) = a_1\phi_1(x) + a_2\phi_2(x) = \sum_{j=1}^{2} a_j\phi_j(x) \\ &\cdots \\ &W(x) = a_1\phi_1(x) + a_2\phi_2(x) + \cdots + a_n\phi_n(x) = \sum_{j=1}^{n} a_j\phi_j(x) \end{aligned} \tag{3.4.137}$$

where a_j are undetermined coefficients and $\phi_j(x)$ are suitable trial functions satisfying all, or at least the geometric boundary conditions. The coefficients $a_j (j = 1, 2, \ldots, n)$ are determined so that Rayleigh's quotient has a minimum. With Eqs. (3.4.137) inserted into Eq. (3.4.133), Rayleigh's quotient becomes

$$\Omega^2 = \frac{\sum_{i=1}^{n}\sum_{j=1}^{n} k_{ij}a_ia_j}{\sum_{i=1}^{n}\sum_{j=1}^{n} m_{ij}a_ia_j} \qquad n = 1, 2, \ldots \tag{3.4.138}$$

where $k_{ij} = k_{ji}$ and $m_{ij} = m_{ji}$ $(i, j = 1, 2, \ldots, n)$ are symmetric stiffness and mass coefficients whose nature depends on the potential energy and kinetic energy, respectively. The special case in which $n = 1$ represents Rayleigh's energy method. For $n \geq 2$, minimization of Rayleigh's quotient leads to the solution of the eigenvalue problem

$$\sum_{j=1}^{n} k_{ij}a_j = \Omega^2 \sum_{j=1}^{n} m_{ij}a_j \qquad i = 1, 2, \ldots, n; n = 2, 3, \ldots \tag{3.4.139}$$

Equations (3.4.139) can be written in the matrix form

$$K\mathbf{a} = \Omega^2 M\mathbf{a} \tag{3.4.140}$$

in which $K = [k_{ij}]$ is the symmetric stiffness matrix and $M = [m_{ij}]$ is the symmetric mass matrix. Equation (3.4.140) resembles the eigenvalue problem for multi-degree-of-freedom systems, Eq. (3.4.76), and its solutions possess the same properties. The eigenvalues Ω_r^2 provide approximations to the actual eigenvalues ω_r^2, and approach them from above as n increases. Moreover, the eigenvectors $\mathbf{a}_r = [a_{r1}\ a_{r2} \ldots a_{rn}]^T$ can be used to obtain the approximate natural modes by writing

$$W_r(x) = a_{r1}\phi_1(x) + a_{r2}\phi_2(x) + \cdots + a_{rn}\phi_n(x) = \sum_{j=1}^{n} a_{rj}\phi_j(x)$$
$$r = 1, 2, \ldots, n; n = 2, 3, \ldots \tag{3.4.141}$$

As an illustration, consider the same rod in axial vibration used to demonstrate Rayleigh's energy method. Insert Eqs. (3.4.137) with $W(x)$ replaced by $U(x)$ into the numerator and denominator of Eq. (3.4.134) to obtain

$$\int_0^L EA(x)\left[\frac{dU(x)}{dx}\right]^2 dx = \sum_{i=1}^{n}\sum_{j=1}^{n}\left[\int_0^L EA(x)\frac{d\phi_i(x)}{dx}\frac{d\phi_j(x)}{dx}dx\right]a_ia_j \tag{3.4.142a}$$

$$\int_0^L m(x)U^2(x)\,dx + MU^2(L) = \sum_{i=1}^{n}\sum_{j=1}^{n}\left[\int_0^L m(x)\phi_i(x)\phi_j(x)dx + M\phi_i(L)\phi_j(L)\right]a_ia_j \tag{3.4.142b}$$

so that the stiffness and mass coefficients are

$$k_{ij} = \int_0^L EA(x)\frac{d\phi_i(x)}{dx}\frac{d\phi_j(x)}{dx}dx \qquad i, j = 1, 2, \ldots, n \tag{3.4.143a}$$

$$m_{ij} = \int_0^L m(x)\phi_i(x)\phi_j(x)\,dx + M\phi_i(L)\phi_j(L) \qquad i, j = 1, 2, \ldots, n \tag{3.4.143b}$$

respectively. As trial functions, use

$$\phi_j(x) = (x/L)^j \qquad j = 1, 2, \ldots, n \tag{3.4.144}$$

which are zero at $x = 0$, thus satisfying the geometric boundary condition. Hence, the stiffness and mass coefficients are

$$k_{ij} = \frac{EAij}{L^{i+j}}\int_0^L x^{i-1}x^{j-1}dx = \frac{ij}{i+j-1}\frac{EA}{L} \qquad i, j = 1, 2, \ldots, n \tag{3.4.145a}$$

$$m_{ij} = \frac{m}{L^{i+j}}\int_0^L x^ix^j dx + M = \frac{mL}{i+j+1} + M \qquad i, j = 1, 2, \ldots, n \tag{3.4.145b}$$

so that the stiffness and mass matrices are

$$K = \frac{EA}{L}\begin{bmatrix} 1 & 1 & 1 & \cdots & 1 \\ 1 & 4/3 & 3/2 & \cdots & 2n/(n+1) \\ 1 & 3/2 & 9/5 & \cdots & 3n/(n+2) \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 1 & 2n/(n+1) & 3n/(n+2) & \cdots & n^2/(2n-1) \end{bmatrix} \tag{3.4.146a}$$

$$M = mL\begin{bmatrix} 1/3 & 1/4 & 1/5 & \cdots & 1/(n+2) \\ 1/4 & 1/5 & 1/6 & \cdots & 1/(n+3) \\ 1/5 & 1/6 & 1/7 & \cdots & 1/(n+4) \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 1/(n+2) & 1/(n+3) & 1/(n+4) & \cdots & 1/(2n+1) \end{bmatrix} + M\begin{bmatrix} 1 & 1 & 1 & \cdots & 1 \\ 1 & 1 & 1 & \cdots & 1 \\ 1 & 1 & 1 & \cdots & 1 \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 1 & 1 & 1 & \cdots & 1 \end{bmatrix} \tag{3.4.146b}$$

For comparison purposes, consider the case in which $M = mL$. Then, for $n = 2$, the eigenvalue problem is

$$\begin{bmatrix} 1 & 1 \\ 1 & 4/3 \end{bmatrix}\begin{bmatrix} a_1 \\ a_2 \end{bmatrix} = \lambda\begin{bmatrix} 4/3 & 5/4 \\ 5/4 & 6/5 \end{bmatrix}\begin{bmatrix} a_1 \\ a_2 \end{bmatrix}$$
$$\lambda = \Omega^2\frac{mL^2}{EA} \tag{3.4.147}$$

which has the solutions

$$\begin{aligned} \lambda_1 &= 0.7407 \qquad \mathbf{a}_1 = [1 \quad -0.1667]^T \\ \lambda_2 &= 12.0000 \qquad \mathbf{a}_2 = [1 \quad -1.0976]^T \end{aligned} \tag{3.4.148}$$

Hence, the computed natural frequencies and modes are

$$\Omega_1 = 0.8607\sqrt{\frac{EA}{mL^2}} \qquad U_1(x) = \frac{x}{L} - 0.1667\left(\frac{x}{L}\right)^2$$
$$\Omega_2 = 3.4641\sqrt{\frac{EA}{mL^2}} \qquad U_2(x) = \frac{x}{L} - 1.0976\left(\frac{x}{L}\right)^2 \tag{3.4.149}$$

Comparing Eqs. (3.4.149) with the estimates obtained by Rayleigh's energy method, Eqs. (3.4.136), note that the Rayleigh-Ritz method has produced a more accurate approximation for the lowest natural frequency. In addition, it has produced a first approximation for the second lowest natural frequency, as well as approximations for the two lowest modes, which Rayleigh's energy method is unable to produce. The approximate solutions can be improved by letting $n = 3, 4, \ldots$.

Finite Element Method In the Rayleigh-Ritz method, the trial functions extend over the entire domain of the system and tend to be complicated and difficult to work with. More importantly, they often cannot be produced, particularly for two-dimensional problems. Another version of the Rayleigh-Ritz method, the **finite element method,** does not suffer from these drawbacks. Indeed, the trial functions extending only over small subdomains, referred to as **finite elements,** are known low-degree polynomials and permit easy computer coding. As in the Rayleigh-Ritz method, a solution is assumed in the form of a linear combination of trial functions, known as **interpolation functions,** multiplied by undetermined coefficients. In the finite element method the coefficients have physical meaning, as they represent "nodal" displacements, where "nodes" are boundary points between finite elements. The computation of the stiffness and mass matrices is carried out for each of the elements separately and then the element stiffness and mass matrices are assembled into global stiffness and mass matrices. One disadvantage of the finite element method is that it requires a large number of degrees of freedom.

To illustrate the method, and for easy visualization, consider the transverse vibration of a string fixed at $x = 0$ and with a spring of stiffness K attached at $x = L$ (Fig. 3.4.27) and divide the length L into n elements of width h, so that $nh = L$. Denote the displacements of the nodal points x_e by a_e and assume that the string displacement is linear between any two nodal points. Figure 3.4.28 shows a typical element e.

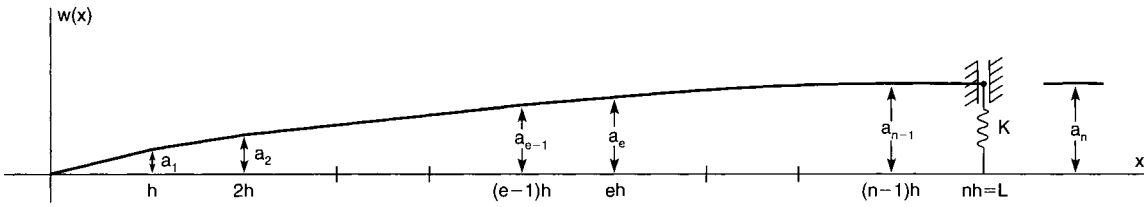

Fig. 3.4.27

The process can be simplified greatly by introducing the nondimensional local coordinate $\xi = j - x/h$. Then, considering the two linear interpolation functions

$$\phi_1(\xi) = \xi \qquad \phi_2(\xi) = 1 - \xi \tag{3.4.150}$$

the displacement at point ξ can be expressed as

$$\omega(\xi) = a_{e-1}\phi_1(\xi) + a_e\phi_2(\xi) \tag{3.4.151}$$

where a_{e-1} and a_e are the nodal displacements for element e. Using Eqs. (3.4.143) and changing variables from x to ξ, we can write the element stiffness and mass coefficients

$$k_{eij} = \frac{1}{h}\int_0^1 EA\,\frac{d\phi_i}{d\xi}\frac{d\phi_j}{d\xi}\,d\xi \qquad m_{eij} = h\int_0^1 m\phi_i\phi_j\,d\xi, \qquad i,j = 1,2 \tag{3.4.152}$$

Introducing Eq. (3.4.151) into Eqs. (3.4.152) and considering the boundary conditions, we obtain the element stiffness and mass matrices

$$K_1 = \frac{EA}{h} \qquad K_e = \frac{EA}{h}\begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} \qquad e = 2, 3, \ldots, n-1$$
$$K_n = \frac{EA}{h}\begin{bmatrix} 1 & -1 \\ -1 & Kh/EA \end{bmatrix} \qquad M_1 = \frac{hm}{3}$$
$$M_e = \frac{hm}{6}\begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix} \qquad e = 2, 3, \ldots, n \tag{3.4.153}$$

where K_1 and M_1 are really scalars, because the left end of the first element is fixed, so that the displacement is zero. Then, since the nodal

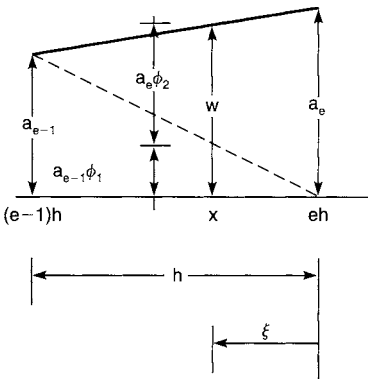

Fig. 3.4.28

displacement a_e is shared by elements e and $e+1$ ($e = 1, 2, \ldots, n-2$), the element stiffness and mass matrices can be assembled into the global stiffness and mass matrices

$$K = \frac{EA}{h}\begin{bmatrix} 2 & -1 & 0 & \cdots & 0 & 0 \\ -1 & 2 & -1 & \cdots & 0 & 0 \\ 0 & -1 & 2 & \cdots & 0 & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & 0 & \cdots & 2 & -1 \\ 0 & 0 & 0 & \cdots & -1 & Kh/EA \end{bmatrix} \tag{3.4.154}$$

$$M = \frac{hm}{6}\begin{bmatrix} 4 & 1 & 0 & \cdots & 0 & 0 \\ 1 & 4 & 1 & \cdots & 0 & 0 \\ 0 & 1 & 4 & \cdots & 0 & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & 0 & \cdots & 4 & 1 \\ 0 & 0 & 0 & \cdots & 1 & 2 \end{bmatrix}$$

For beams in bending, the displacements consist of one translation and one rotation per node; the interpolation functions are the Hermite cubics

$$\phi_1(\xi) = 3\xi^2 - 2\xi^3, \phi_2(\xi) = \xi^2 - \xi^3$$
$$\phi_3(\xi) = 1 - 3\xi^2 + 2\xi^3, \phi_4(\xi) = -\xi + 2\xi^2 - \xi^3 \quad (3.4.155)$$

and the element stiffness and mass coefficients are

$$k_{eij} = \frac{1}{h^3}\int_0^1 EI\frac{d^2\phi_i}{d\xi^2}\frac{d^2\phi_j}{d\xi^2}\,d\xi \qquad m_{eij} = h\int_0^1 m\phi_i\phi_j\,d\xi$$
$$i, j = 1, 2, 3, 4 \quad (3.4.156)$$

yielding typical element stiffness and mass matrices

$$K_e = \frac{EI}{h^3}\begin{bmatrix} 12 & 6 & -12 & 6 \\ 6 & 4 & -6 & 2 \\ -12 & -6 & 12 & -6 \\ 6 & 2 & -6 & 4 \end{bmatrix}$$
$$M_e = \frac{hm}{420}\begin{bmatrix} 156 & 22 & 54 & -13 \\ 22 & 4 & 13 & -3 \\ 54 & 13 & 156 & -22 \\ -13 & -3 & -22 & 4 \end{bmatrix} \quad (3.4.157)$$

The treatment of two-dimensional problems, such as for membranes and plates, is considerably more complex (see Meirovitch, "Principles and Techniques of Vibration," Prentice-Hall) than for one-dimensional problems.

The various steps involved in the finite element method lend themselves to ready computer programming. There are many computer codes available commercially; one widely used is NASTRAN.

VIBRATION-MEASURING INSTRUMENTS

Typical quantities to be measured include acceleration, velocity, displacement, frequency, damping, and stress. Vibration implies motion, so that there is a great deal of interest in transducers capable of measuring motion relative to the inertial space. The basic transducer of many vibration-measuring instruments is a mass-damper-spring enclosed in a case together with a device, generally electrical, for measuring the displacement of the mass relative to the case, as shown in Fig. 3.4.29. The equation for the displacement $z(t)$ of the mass relative to the case is

$$m\ddot{z}(t) + c\dot{z}(t) + kz(t) = -m\ddot{y}(t) \quad (3.4.158)$$

where $y(t)$ is the displacement of the case relative to the inertial space. If this displacement is harmonic, $y(t) = Y \sin \omega t$, then by analogy with Eq. (3.4.35) the response is

$$z(t) = Y\left(\frac{\omega}{\omega_n}\right)^2 |G(\omega)| \sin(\omega t - \phi)$$
$$= Z(\omega)\sin(\omega t - \phi) \quad (3.4.159)$$

so that the magnitude factor $Z(\omega)/Y = (\omega/\omega_n)^2\,|G(\omega)|$ is as plotted in Fig. 3.4.9 and the phase angle ϕ is as in Fig. 3.4.4. The plot $Z(\omega)/Y$ versus ω/ω_n is shown again in Fig. 3.4.30 on a scale more suited to our purposes.

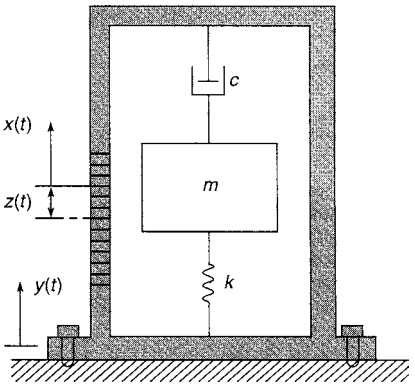

Fig. 3.4.29

Accelerometers are high-natural-frequency instruments. Their usefulness is limited to a frequency range well below resonance. Indeed, for small values of ω/ω_n, Eq. (3.4.159) yields the approximation

$$Z(\omega) \approx \frac{1}{\omega_n^2}\omega^2 Y \quad (3.4.160)$$

so that the signal amplitude is proportional to the amplitude of the acceleration of the case relative to the inertial space. For $\xi = 0.7$, the accelerometer can be used in the range $0 \le \omega/\omega_n \le 0.4$ with less than 1 percent error, and the range can be extended to $\omega/\omega_n \le 0.7$ if proper corrections, based on instrument calibration, are made.

Commonly used accelerometers are the compression-type piezoelectric accelerometers. They consist of a mass resting on a piezoelectric ceramic crystal, such as quartz, tourmaline, or ferroelectric ceramic, with the crystal acting both as spring and sensor. Piezoelectric actuators have negligible damping, so that their range must be smaller, such as $0 < \omega/\omega_n < 0.2$. In view of the fact, however, that the natural frequency is very high, about 30,000 Hz, this is a respectable range.

Displacement-Measuring Instruments These are low-natural-frequency devices and their usefulness is limited to a frequency range well above resonance. For $\omega/\omega_n \gg 1$, Eq. (3.4.159) yields the approximation

$$Z(\omega) \approx Y \quad (3.4.161)$$

so that the signal amplitude is proportional to the amplitude of the case displacement. Instruments with low natural frequency compared to the excitation frequency are known as **seismometers.** They are commonly used to measure ground motions, such as those caused by earthquakes or underground nuclear explosions. The requirement of low natural frequency dictates that the mass, referred to as **seismic mass,** be very large and the spring very soft, so that essentially the mass remains

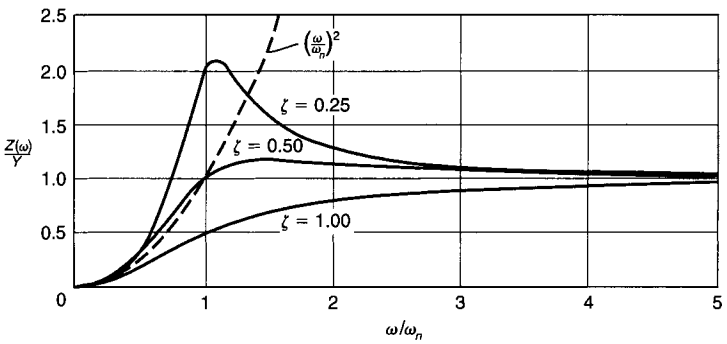

Fig. 3.4.30

stationary in an inertial space while the case attached to the ground moves relative to the mass.

Seismometers tend to be considerably larger in size than accelerometers. If a large-size instrument is undesirable, or even if size is not an issue, displacements in harmonic motion, as well as velocities, can be obtained from accelerometer signals by means of electronic integrators.

Some other transducers, not mass-damper-spring transducers, are as follows (Harris, "Shock and Vibration Handbook," 3d ed., McGraw-Hill):

Differential-transformer pickups: They consist of a core of magnetic material attached to the vibrating structure, a primary coil, and two secondary coils. As the core moves, both the inductance and induced voltage of one secondary coil increase while those of the other decrease. The output voltage is proportional to the displacement over a wide range. Such pickups are used for very low frequencies, up to 60 Hz.

Strain gages: They consist of a grid of fine wires which exhibit a change in electrical resistance proportional to the strain experienced. Their flimsiness requires that strain gages be either mounted on or bonded to some carrier material.

4.1 THERMODYNAMICS

by Peter E. Liley

NOTE: References are placed throughout the text for the reader's convenience. (No material is presented relating to the calibration of thermometers at fixed points, etc. Specific details of the measurement of temperature, pressure, etc. are found in Benedict, "Fundamentals of Temperature, Pressure and Flow Measurements," 3d ed. Measurement of other properties is reviewed in Maglic et al., "Compendium of Thermophysical Property Measurement Methods," vol. 1, Plenum Press. The periodical *Metrologia* presents latest developments, particularly for work of a definitive caliber.)

Thermodynamic properties of a variety of other specific materials are listed also in Secs. 4.2, 6.1, and 9.8.

THERMOMETER SCALES

Let F and C denote the readings on the Fahrenheit and Celsius (or centigrade) scales, respectively, for the same temperature. Then

$$C = \frac{5}{9}(F - 32) \qquad F = \frac{9}{5}C + 32$$

If the pressure readings of a constant-volume hydrogen thermometer are extrapolated to zero pressure, it is found that the corresponding temperature is −273.15°C, or −459.67°F. An **absolute temperature scale** was formerly used on which zero corresponding with zero pressure on the hydrogen thermometer. The basis now used is to define and give a numerical value to the temperature at a single point, the triple point of water, defined as 0.01°C. The scales are:

Kelvins (K) = degrees Celsius + 273.15
Degrees Rankine (°R) = degrees Fahrenheit + 459.67

EXPANSION OF BODIES BY HEAT

Coefficients of Expansion The **coefficient of linear expansion** a' of a solid is defined as the increment of length in a unit of length for a rise in temperature of 1 deg. Likewise, the **coefficient of cubical expansion** a''' of a solid, liquid, or gas is the increment of volume of a unit volume for a rise of temperature of 1 deg. Denoting these coefficients by a' and a''', respectively, we have

$$a' = \frac{1}{l}\frac{dl}{dt} \qquad a''' = \frac{1}{V}\frac{dV}{dt}$$

in which l denotes length, V volume, and t temperature. For homogeneous solids $a''' = 3a'$, and the **coefficient of area expansion** $a'' = 2a'$.

The coefficients of expansion are, in general, dependent upon the temperature, but for ordinary ranges of temperature, constant mean values may be taken. If lengths, areas, and volumes at 32°F (0°C) are taken as standard, then these magnitudes at other temperatures t_1 and t_2 are related as follows:

$$\frac{l_1}{l_2} = \frac{1 + a't_1}{1 + a't_2} \qquad \frac{A_1}{A_2} = \frac{1 + a''t_1}{1 + a''t_2} \qquad \frac{V_1}{V_2} = \frac{1 + a'''t_1}{1 + a'''t_2}$$

Since for solids and liquids the expansion is small, the preceding formulas for these bodies become approximately

$$l_2 - l_1 = a'l_1(t_2 - t_1)$$
$$A_2 - A_1 = a''A_1(t_2 - t_1)$$
$$V_2 - V_1 = a'''V_1(t_2 - t_1)$$

The coefficients of cubical expansion for different gases at ordinary temperatures are about the same. From 0 to 212°F and at atmospheric pressure, the values multiplied by 1,000 are as follows: for NH_3, 2.11; CO, 2.04; CO_2, 2.07; H_2, 2.03; NO, 2.07. For an ideal gas, the coefficient at any temperature is the reciprocal of the (absolute) temperature. (See also Table 6.1.10.)

UNITS OF FORCE AND MASS

Force mass, length, and time are related by Newton's second law of motion, which may be expressed as

$$F \sim ma$$

In order to write this as an equality, a constant must be introduced which has magnitude and dimensions. For convenience, in the fps system, the constant may be designated as $1/g_c$. Thus,

$$F = \frac{ma}{g_c}$$

Since this equation must be homogeneous insofar as the dimensions are concerned, the units for g_c are $mL/(t^2F)$. Consider a 1-lb mass, lbm, in the earth's gravitational field, where the acceleration is 32.1740 ft/s^2. The force exerted on the pound mass will be defined as the pound force, lbf. This system of units gives for g_c the following magnitude and dimensions:

$$1 \text{ lbf} = \frac{(1 \text{ lbm})(32.174 \text{ ft/s}^2)}{g_c}$$

hence

$$g_c = 32.174 \text{ lbm·ft/(lbf·s}^2)$$

Note that g_c may be used with other units, in which case the numerical value changes. The numerical value of g_c for four systems of units is

$$g_c = 32.174 \frac{\text{lbm·ft}}{\text{lbf·s}^2} = 1 \frac{\text{slug·ft}}{\text{lbf·s}^2} = 1 \frac{\text{lbm·ft}}{\text{pdl·s}^2} = 1 \frac{\text{g·cm}}{\text{dyn·s}^2}$$

In SI, the constant is chosen to be unity and $F(\text{N}) = m(\text{kg})a(\text{m/s}^2)$. There are four possible constants, and all have been used. (See Blackman, "SI Units in Engineering," Macmillan.)

Consider now the relationship which involves weight, a gravitational force, and mass by applying the basic equation for a body of fixed mass acted upon by a gravitational force g and no other forces. The acceleration of the mass caused by the gravitational force is the acceleration due to gravity g.

Substituting gives the relationship between weight and mass

$$w = \frac{mg}{g_c}$$

If the gravitational acceleration is constant, the weight and mass are in a fixed proportion to each other; hence for accounting purposes in mass balances they can be used interchangeably. This is not possible if g is a variable.

We may now write the relation between mass m and weight w as

$$w = m\frac{g}{g_c}$$

The constant g_c is used throughout the following paragraphs. (An extensive table of conversion factors from customary units to SI units is found in Sec. 1.)

The SI unit of pressure is the newton per square metre. It is a very small pressure, as normal atmospheric pressure is 1.01325×10^5 N/m^2. While some use has been made of the pressure expressed in kN/m^2 or kPa (1 Pa = 1 N/m^2) and in MN/m^2 or MPa, the general techni-

cal usage now seems to favor the bar $= 10^5$ N/m$^2 = 10^5$ Pa so that 1 atm = 1.01325 bar. For many approximate calculations the atmosphere and the bar can be equated.

Many representative accounts of the measurement of low and high pressure have appeared. (See, for example, Lawrance, *Chem. Eng. Progr.,* **50,** 1954, p. 155; Leck, "Pressure Measurement in Vacuum Systems," Inst. Phys., London, 1957; Peggs, "High Pressure Measurement Techniques," Appl. Sci. Publishers, Barking, Essex.)

MEASUREMENT OF HEAT

Units of Heat Many units of heat have been dependent on the experimentally determined properties of some substance. To eliminate experimental variations, the unit of heat may be defined in terms of fundamental units. The International Steam Table Conference (London, 1929) defines the Steam Table (IT) calorie as 1/860 of a watthour. One British thermal unit (Btu) is defined as 251.996 IT cal, 778.26 ft · lb.

Previously, the Btu was defined as the heat necessary to raise one pound of water one degree Fahrenheit at some arbitrarily chosen temperature level. Similarly, the calorie was defined as the heat required to heat one gram of water one degree Celsius at 15°C (or at 17.5°C). These units are roughly the same in value as those mentioned above. In SI, the **joule** is the heat unit, and the newton-metre the work unit of energy. The two are equal, so that 1 J = 1 N · m; that is, in SI, the mechanical equivalent of heat is unity.

Heat Capacity and Specific Heat The **heat capacity** of a material is the amount of heat transferred to raise a unit mass of a material 1 deg in temperature. The ratio of the amount of heat transferred to raise unit mass of a material 1 deg to that required to raise unit mass of water 1 deg at some specified temperature is the **specific heat** of the material. For most engineering purposes, heat capacities may be assumed numerically equal to specific heats. Two heat capacities are generally used, that at constant pressure c_p and that at constant volume c_v. For unit mass, the instantaneous heat capacities are defined as

$$\left(\frac{\partial h}{\partial t}\right)_p = c_p \qquad \left(\frac{\partial u}{\partial t}\right)_v = c_v$$

Over a range in temperature, the mean heat capacities are given by

$$c_{pm} = \frac{1}{t_2 - t_1}\int_{t1}^{t2} c_p\,dt \qquad c_{vm} = \frac{1}{t_2 - t_1}\int_{t1}^{t2} c_v\,dt$$

Denoting by c the heat capacity, the heat required to raise the temperature of m lb of a substance from t_1 to t_2 is $Q = mc(t_2 - t_1)$, provided c is a constant.

In general, c varies with the temperature, though for moderate temperature ranges a constant mean value may be taken. If. however. c is taken as varable, $Q = m\int_{t1}^{t2} c\,dt$. The *mean* heat capacity from 0 to t deg is given by $c_m = \frac{1}{t}\int_0^t c\,dt$. If $c = a_1 + a_2t + a_3t^2 + \cdots$

$$c_m = a_1 + \tfrac{1}{2}a_2t + \tfrac{1}{3}a_3t^2 + \cdots$$

Data for the specific heat of some solids, liquids, and gases are found in Tables 4.2.22 and 4.2.27.

Specific Heat of Solids For eleraents near room temperature, the specific heat may be approximated by the rule of Dulong and Petit, that the specific heat at constant volume approaches 3*R*. At lower temperatures, Debye's theory leads to the equation

$$\frac{C_v}{R} = 3\left(\frac{T}{\Theta}\right)\int_0^{\Theta_{\max}T}\left(\frac{\Theta}{T}\right)^4 \frac{\exp(\Theta/T)}{[\exp(\Theta/T) - 1]^2}\,d\left(\frac{\Theta}{T}\right)$$

commonly known as Debye's function. Figure 4.1.1 shows the variation of c_v/R with T/Θ, as predicted from the equation above. The principal difficulties in using the Debye equation arise from (1) the difficulty in finding unique values of Θ for any given material and (2) the need to consider other contributions to the specific heat. For further references on the Debye equation, see Harrison and Neighbours. *U.S. Naval Postgraduate Lab. Rept. 49,* Dec. 1964; Overton and Hancock, *Naval Research Lab. Rept. 5502,* 1960; Hilsenrath and Zeigler, *NBS Monograph 49,* 1962. For a thorough discussion of electronic, lattice, and magnetic contributions to specific heat, see Gopal, "Specific Heats at Low Temperatures," Plenum Press, New York. See also Table 6.1.11.

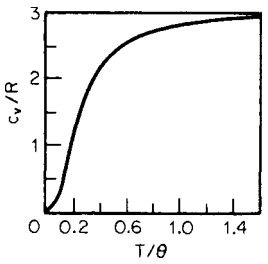

Fig. 4.1.1

For solid compounds at about room temperature, Kopp's approximation is often useful. This states that the specific heat of a solid compound at room temperature is equal to the sum of the specific heats of the atoms forming the compound.

SPECIFIC HEAT OF LIQUIDS

No general theory of any simple practical utility seems to exist for the specific heat of liquids. In "Thermophysical Properties of Refrigerants," ASHRAE, Atlanta, 1976, the interpolation device was a polynomial in temperature, usually up to T^3.

SPECIFIC HEAT OF GASES

The following table summarizes results of kinetic theory for specific heats of gases:

Gas Type	c_p/R	c_v/R	c_p/c_v
Monatomic	5/2	3/2	5/3
Diatomic	7/2	5/2	7/5
n degrees of freedom	$(n + 2)/2$	$n/2$	$1 + 2/n$

Determination of the effective number of degrees of freedom limits extending this method to more comlex gases.

Properties of gases are, usually, most readily correlated on the mol basis. A **pound mol** is the mass in pounds equal to the molecular weight. Thus 1 pound mol of oxygen is 32 lb. At the same pressure and temperature, the volume of 1 mol is the same for all perfect gases, i.e., following the gas laws. Experimental findings led Avogadro (1776–1856) to formulate the microscopic hypothesis now known as **Avogadro's principle,** which states that 1 mol of any perfect gas contains the same number of molecules. The number is known as the **Avogadro number** and is equal to

$$N = 6.02214 \times 10^{26}\ \text{molecules/(kg·mol)}$$
$$= 2.73160 \times 10^{26}\ \text{molecules/(lb·mol)}$$

For perfect gases, $Mc_p - Mc_v = MR = 1.987$.

$$c_i = R/(k - 1) \qquad c_p = Rk(k - 1)$$

Passut and Danner [*Ind. Eng. Chem. Process Design & Dev.* (**11,** 1972, p. 543)] developed a set of thermodynamically consistent polynomials for estimating ideal gas enthalpy, entropy, and heat capacity, fittings being given for 89 compounds. The same journal reported 2 years later an extension of the work to another 57 compounds, by Huang and Daubert. Fittings of a cubic-in-temperature polynomial for 408 hydrocarbons and related compounds in the ideal gas state were reported by Thinh et al. in *Hydrocarhon Processing,* Jan. 1971. pp. 98–104. On p. 153 of a later issue (Aug. 1976), they claimed that the function $C_p = A + B\exp(-c/T^n)$ fitted for 221 hydrocarbons: graphite

and hydrogen gave a more accurate fit. A cubic polynomial in temperature was also fitted for more than 700 compounds from 273 to 1,000 K by Seres et al. in *Acta Phys. Chem.,* Univ. Szegediensis (Hungary), **23,** 1977, pp. 433–468. A 1975 formula of Wilhoit was fitted for 62 substances by A. Harmens in *Proc. Conf. Chemical Thermodynamic Data on Fluids,* IPC Sci. Tech. Press, Guildford, U.K., pp. 112–120. A cubic polynomial fitting for 435 substances appeared in *J. Chem. Eng., Peking*(**2,** 1979, pp. 109–132). The reader is reminded that specific heat at constant pressure values can readily be calculated from tabulated enthalpy-temperature tables, for any physical state. Table 4.2.22 gives values for liquids and gases, while Tables 4.2.27 to 4.2.29 provide similar information for selected solids.

SPECIFIC HEAT OF MIXTURES

If w_1 lb of a substance at temperature t_1 and with specific heat c_1 is mixed with w_2 lb of a second substance at temperature t_2 and with specific heat c_2, provided chemical reaction, heat evolution, or heat absorption does not occur, the specific heat of the mixture is

$$c_m = (w_1c_1 + w_2c_2)/(w_1 + w_2)$$

and the temperature of the mixture is

$$t_m = (w_1c_1t_1 + w_2c_2t_2)/(w_1c_1 + w_2c_2)$$

In general, $t_m = \Sigma wct/\Sigma wc$.

To raise the temperature of w_1 lb of a substance having a specific heat c_1 from t_1 to t_m, the weight w_2 of a second substance required is

$$w_2 = w_1c_1(t_m - t_1)/c_2(t_2 - t_m)$$

SPECIFIC HEAT OF SOLUTIONS

For aqueous solutions of salts, the specific heat may be estimated by assuming the specific heat of the solution equal to that of the water alone. Thus, for a 20 percent by weight solution of sodium chloride in water, the specific heat would be approximately 0.8.

Although approximate calculations of mixture properties often consist simply of multiplying the mole fraction of each constituent by the property of each constituent, more accurate calculations are possible. (See "Technical Data Book—Petroleum Refining" API, Washington, DC, 1984; Daubert, "Chemical Engineering Thermodynamics," McGraw-Hill; "The Properties of Gases and Liquids," 3d ed., McGraw-Hill; Perry, "Chemical Engineers Handbook," McGraw-Hill; Walas, "Phase Equilibria in Chemical Engineering," Butterworth.)

LATENT HEAT

For pure substances, the heat effects accompanying changes in state at constant pressure are known as latent effects, because no temperature change is evident. Heat of fusion, vaporization, sublimation, and change in crystal form are exarnples.

The values for the heat of fusion and latent heat of vaporization are presented in Tables 4.2.21 and 4.2.28.

GENERAL PRINCIPLES OF THERMODYNAMICS

Notation

B = availability (by definition, $B = H - T_oS$)
c_p = specific heat at constant pressure
c_v = specific heat at constant volume
E, e = total energy associated with system
g = local acceleration of gravity, ft/s^2
g_c = a dimensional constant
H, h = enthalpy, Btu (by definition $h = u + pv$)
J = mechanical equivalent of heat = 778.26 ft · lb/Btu = 4.1861 J/cal
$k = c_p/c_v$
m = mass of substance under consideration, lbm
M = molecular weight
p = absolute pressure, lb/ft^2
Q, q = quantity of heat absorbed by system from surroundings, Btu
R = ideal gas constant
R_u = universal gas constant
S, s = entropy
t = temperature, °F
$T = t + 459.69$ = absolute temperature = °R
T_0 = sink or discard temperature
U, u = internal energy
$\bar{v}$ = linear velocity
v = volume
V = total volume
w = weight of substance under consideration, lb
W = external work performed on surroundings during change of state, ft · lb
$Y = \left(\frac{p_1}{p_2}\right)^{(k-1)k} - 1$
z = distance above or below chosen datum
g = free energy (by definition, $g = h - Ts$)
f = Helmholtz free energy (by definition, $f = u - Ts$)
ϵ = exergy

In thermodynamics, unless otherwise noted, the convention followed is that the change in any property $\psi = \Delta\psi$ = final value − initial value = $\psi_2 - \psi_1$.

In this notation, small letters usually denote magnitudes referred to a unit mass of the substance, capital letters corresponding magnitudes referred to m units of mass. Thus, v denotes the volume of 1 lb, and $V = mv$, the volume of m lb. Similarly, $U = mu$, $S = ms$, etc. Subscripts are used to indicate different states; thus, p_1, v_1, T_1, u_1, s_1 refer to state 1; p_2, v_2, T_2, u_2, s_2 refer to state 2; Q_{12} is used to denote the heat transferred during the change from state 1 to state 2, and W_{12} denotes the external work done during the same change.

Thermodynamics is the study which deals with energy, the various concepts and laws describing the conversion of one form of energy to another, and the various systems employed to effect the conversions. Thermodynamics deals in general with systems in equilibrium. By means of its fundamental concepts and basic laws, the behavior of an engineering system may be described when the various variables are altered. Thermodynamics covers a very broad field and includes many systems, for example, those dealing with chemical, thermal, mechanical, and electrical force fields and potentials. The quantity of matter within a prescribed boundary under consideration is called the **system,** and everything external to the system is spoken of as the **surroundings.** With a **closed system** there is no interchange of matter between system and surroundings; with an **open system** there is such an interchange. Any change that the system may undergo is known as a **process.** Any process or series of processes in which the system returns to its original condition or state is called a **cycle.**

Heat is energy **in transit** from one mass to another because of a temperature difference between the two. Whenever a force of any kind acts through a distance, **work** is done. Like heat, work is also energy in transit. Work is to be differentiated from the capacity of a quantity of energy to do work.

The two fundamental and general laws of thermodynamics are: (1) energy may be neither created nor destroyed, (2) it is impossible to bring about any change or series of changes the sole net result of which is transfer of energy as heat from a low to a high temperature; in other words, heat will not of itself flow from low to high temperatures.

The **first law of thermodynamics,** one of the very important laws of nature, is the law of conservation of energy. Although the law has been stated in a variety of ways, all have essentially the same meaning. The following are examples of typical statements: Whenever energy is transformed from one form to another, energy is always conserved; energy can neither be created nor destroyed; the sum total of all energy remains constant. The energy conservation hypothesis was stated by a number of investigators; however, experimental evidence was not available until the famous work of J. P. Joule. Transformation of matter

into energy ($E = mc^2$), as in nuclear reactions, is ignored; within the realm of thermodynamics discussed here, mass is conserved.

It has long been the custom to designate the law of conservation of energy, the first law of thermodynamics, when it is used in the analysis of engineering systems involving heat transfer and work. Statements of the first law may be written as follows: Heat and work are mutually convertible; or, since energy can neither be created nor destroyed, the total energy associated with an energy conversion remains constant.

Before the first law may be applied to the analysis of engineering systems, it is necessary to express it in some form of expression. Thus it may be stated for an **open system** as

$$\left[\begin{array}{l}\text{Net amount of}\\ \text{energy added to}\\ \text{system as heat}\\ \text{and all forms}\\ \text{of work}\end{array}\right] + \left[\begin{array}{l}\text{stored}\\ \text{energy}\\ \text{of mass}\\ \text{entering}\\ \text{system}\end{array}\right] - \left[\begin{array}{l}\text{stored}\\ \text{energy}\\ \text{of mass}\\ \text{leaving}\\ \text{system}\end{array}\right] = \left[\begin{array}{l}\text{net in-}\\ \text{crease}\\ \text{in stored}\\ \text{energy of}\\ \text{system}\end{array}\right]$$

For an open system with fluid entering only at section 1 and leaving only at section 2 and with no electrical, magnetic, or surface-tension effects, this equation may be written as

$$Q + W + \int\left(h_1 + \frac{v_1^2}{2g_c} + \frac{gz_1}{g_c}\right)\delta m_1 - \int\left(h_2 + \frac{v_2^2}{2g_c} + \frac{gz_2}{g_c}\right)\delta m_2 = U_f - U_i + \frac{m_f v_f^2 - m_i v_i^2}{2g_c} + \frac{g}{g_c}(m_f z_f - m_i z_i)$$

Note that the same sign is given to both heat and work transfers. Heat and work added to the system are given a positive sign; heat lost and work output are given a negative sign. The subscripts i and f refer to entire systems before and after the process occurs, and δm refers to a differential quantity of matter.

It must be remembered that all terms in the first-law equation must be expressed in the same units.

For a **closed stationary system,** the first-law expression reduces to

$$Q + W = U_2 - U_1$$

For an **open system** fixed in position but undergoing **steady flow,** e.g., a turbine or reciprocating steam engine, for a mass flow rate of m is

$$\dot{Q} + \dot{W} = \dot{m}\left[(h_2 - h_1) + \frac{v_2^2 - v_1^2}{2g_c} + \frac{8}{g_c}(z_2 - z_1)\right]$$

In a **steady-flow** process, the mass rate of flow into the apparatus is equal to the mass rate of flow out; in addition, at any point in the apparatus, the conditions are unchanging with time.

This condition is usually called the **continuity equation** and is written as

$$\dot{m} = \frac{dm}{dt} = \frac{A\bar{v}}{v} = \frac{A_1\bar{v}}{v_1} = \frac{A_2\bar{v}_2}{v_2}$$

where mass flow rate $\dot{m}$ is related to volume flow rate $\dot{V}$ by $\dot{V} = \dot{m}v$ and A is the cross-sectional area.

Since for many processes the last two terms are often negligible, they will be omitted for simplicity except when such omission would introduce appreciable error.

Work done in overcoming a fluid pressure is measured by $W = -\int p\,dv$, where p is the pressure *effectively* applied to the surroundings for doing work and dv represents the change in volume of the system.

Reversible and Irreversible Processes A **reversible** process is one in which both the system and the surroundings may be returned to their original states. After an **irreversible** process, this is not possible. No process involving friction or an unbalanced potential can be reversible. No loss in ability to do work is suffered because of a reversible process, but there is always a loss in ability to do work because of an irreversible process. All actual processes are irreversible. Any series of reversible processes that starts and finishes with the system in the same state is called a **reversible cycle.**

Steady-Flow Processes With **steady flow,** the conditions at any point in an apparatus through which a fluid is flowing do not change progressively with time. Steady-flow processes involving only mechanical effects are equivalent to similar nonflow processes occurring between two weightless frictionless diaphragms or pistons moving at constant pressure with the system as a whole in motion. Under these circumstances, the total work done by or on a unit amount of fluid is made up of that done on the two diaphragms $p_2v_2 - p_1v_1$ and that done on the rest of the surroundings $-\int p\,dv - p_2v_2 + p_1v_1$. Differentiating, $-p\,dv - d(p)v = v\,dp$. The net, useful flow work done on the surroundings is $\int v\,dp$. This is often called the shaft work. The net, useful or shaft work differs from the total work by $p_2v_2 - p_1v_1$. The first-law equation may be written to indicate this result for a unit mass flow rate as

$$q + W_{\text{net}} = u_2 - u_1 + p_2v_2 - p_1v_1 + \frac{1}{2g_c}(\bar{v}_2^2 - \bar{v}_1^2) + \frac{g}{g_c}(z_2 - z_1)$$

or, since by definition

$$u + pv = h$$

$$q + W_{\text{net}} = h_2 - h_1 + \frac{1}{2g_c}(\bar{v}_2^2 - \bar{v}_1^2) + \frac{g}{g_c}(z_2 - z_1)$$

If all net work effects are mechanical,

$$q + \int v\,dp = h_2 - h_1 + \frac{1}{2g_c}(\bar{v}_2^2 - \bar{v}_1^2) + \frac{g}{g_c}(z_2 - z_1)$$

Since in evaluating $\int v\,dp$ the pressure is that *effectively* applied to the surroundings, the integration cannot usually be performed except for reversible processes.

If a fluid is passed adiabatically through a conduit (i.e., without heat exchange with the conduit), without doing any net or useful work, and if velocity and potential effects are negligible, $h_2 = h_1$. A process of the kind indicated is the Joule-Thomson flow, and the ratio $(\partial T/\partial p)_h$ for such a flow is the Joule-Thomson coefficient.

If a fluid is passed through a nonadiabatic conduit without doing any net or useful work and if velocity and potential effects are negligible, $q = h_2 - h_1$. This equation is important in the calculation of heat balances on flow apparatus, e.g., condensers, heat exchangers, and coolers.

In many engineering processes the movement of materials is not independent of time; hence the steady-flow equations do not apply. For example, the process of oxygen discharging from a storage bottle represents a transient condition. The pressure within the bottle changes as the amount of oxygen in the tank decreases. The analysis of some transient processes is very complex; however, in order to show the general approach, a simple case will be considered.

The quantity of material flowing into and out of the engineering system in Fig. 4.1.2 varies with time. The amount of work and the heat transfer crossing the system boundary are likewise dependent upon time. According to the law of conservation of mass, the rate of change of mass within the system is equal to the rate of mass flow into and out

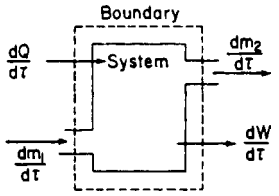

Fig. 4.1.2 Variable-flow system.

of the system. Hence, in terms of mass flow rates,

$$\frac{dm_s}{d\tau} = \frac{dm_1}{d\tau} - \frac{dm_2}{d\tau}$$

For a finite period of time, this relation may be expressed as

$$\Delta m_s = \Delta m_1 - \Delta m_2$$

The first law may be written as follows:

$$\frac{dU_s}{d\tau} = \frac{dQ}{d\tau} + \frac{dW}{d\tau} + \left(h_1 + \frac{\bar{v}_1^2}{2g_c} + \frac{g}{g_c} z_1\right)\frac{dm_1}{d\tau} - \left(h_2 + \frac{\bar{v}_2^2}{2g_c} + \frac{g}{g_c} z_2\right)\frac{dm_2}{d\tau}$$

Under non-steady-flow conditions the variables h, $\bar{v}$, z may change with time as well as flow rate, in which case the solution is very involved.

If steady-flow conditions prevail, then ΔU_s is equal to 0 and the integrands are independent of time, in which case the above equation reduces to the familiar steady-flow relation.

The **second law of thermodynamics** is a statement that conversion of heat to work is limited by the temperature at which conversion occurs. It may be shown that:

1. No cycle can be more efficient than a reversible cycle operating between given temperature limits.
2. The efficiency of all reversible cycles absorbing heat only at a single constant higher temperature T_1 and rejecting heat only at a single constant lower temperature T_2 must be the same.
3. For all such cycles, the efficiency is

$$\eta = \frac{W}{Q_1} = \frac{T_1 - T_2}{T_1}$$

This is usually called the **Carnot cycle efficiency.** By the first law $W = Q_1 - Q_2$,

$$(Q_1 - Q_2)/Q_1 = (T_1 - T_2)/T_1$$

By algebraic rearrangement,

$$Q_1/T_1 = Q_2/T_2$$

Clapeyron Equation

$$\frac{dp}{dT} = \frac{Q}{TV_{12}}$$

This important relation is useful in calculations relating to constant-pressure evaporation of pure substances. In that case the equation may be written

$$v_{fg} = \frac{h_{fg}}{T\,(dp/dT)}$$

where v_{fg} and h_{fg} are defined on p. 4-14.

ENTROPY

For reversible cyclical processes in which the temperature varies during heat absorption and rejection, i.e., for any *reversible cycle,* $\int (dQ/T) = 0$. Consequently, for any *reversible process,* $\int (dQ/T)$ is not a function of the particular *reversible path* followed. This integral is called the entropy change, or $\int_1^2 (dQ_{\text{rev}}/T) = S_2 - S_1 = S_{12}$. The entropy of a substance is dependent only on its state or condition. Mathematically, dS is a complete or perfect differential and S is a point function in contrast with Q and W which are path functions. For any reversible process, the change in entropy of the system and surroundings is zero, whereas for any irreversible process, the net entropy change is positive.

All actual processes are irreversible and therefore occur with a decrease in the amount of energy available for doing work, i.e., with an increase in unavailable energy. The increase in unavailable energy is the product of two factors, T_0 the lowest available temperature for heat discard (practically always the temperature of the atmosphere) and the net change in entropy. The increase in unavailable energy is $T_0\,\Delta S_{\text{net}}$. Any process that occurs of itself (any **spontaneous process**) will proceed in such a direction as to result in a net increase in entropy. This is an important concept in the application of thermodynamics to chemical processes.

Three important **potentials** used in the Maxwell relations are:

1. The familiar potential, known as **enthalpy,**

$$h = u + pv$$

2. The **free energy** or the **Helmholtz function** is defined by the following relation:

$$f = u - Ts$$

3. The **free enthalpy** or the **Gibbs function** is defined by

$$g = h - Ts = f + pv = u + pv - Ts$$

The names used for these potentials have not gained universal acceptance. In particular, the name **free energy** is used for g in many textbooks on chemical thermodynamics. One should be very cautious when referring to different books or technical papers and should verify by definition, rather than rely on the name of the potential.

Availability of a system or quantity of energy is defined as $g = h - T_0 s$. In this equation, all quantities except T_0 refer to the system irrespective of the state of the surroundings. T_0 is the lowest temperature available for heat discard. The preceding definition assumes the absence of velocity, potential, and similar effects. When these are not negligible, proper allowance must be made, for example, $g = h - T_0 s + \bar{v}^2/(2g_c) + (g/g_c)z$. By substitution of $Q = T_0(S_2 - S_1)$ in the appropriate first-law expressions, it may be shown that for any steady-flow process, or for any constant-pressure nonflow process, decrease in availability is equal to the maximum possible (reversible) net work effect with sink for heat discard at T_0.

The availability function g is of particular value in the thermodynamic analysis of changes occurring in the stages of a turbine and is of general utility in determining thermodynamic efficiencies, i.e., the ratio of actual work performed during a process to that which theoretically should have been performed.

EXERGY

In the following, the general concept of exergy is explained, equations for a few simple processes are given, and three sets of references are added. The first is for information on the basics, the second lists thermodynamic texts, and the final lists references to the exergy of specific topics.

Exergy is a term first suggested by Rant.[13] An alternative term is *availability,* but exergy is now the preferred usage. Exergy is the maximum useful work obtainable from a system and its surroundings.

For a system exchanging heat Q with a reservoir whose temperature T may vary, the exergy is

$$\epsilon = Q - T_0 \int \left(\frac{dQ}{T}\right)$$

where the subscript 0 refers to the surroundings. For a system with enthalpy h and entropy s the exergy is

$$\epsilon = (h + \text{kinetic energy} + \text{potential energy}) - [h_0 + T_0(s - s_0)].$$

The loss of exergy in a system is called the *irreversibility* I, where $I = \epsilon_{\text{in}} - \epsilon_{\text{out}} - \text{useful work}$.[1,24] The useful work is the total work minus the work done against the atmosphere. As $H = U + PV$, we define an exergy function $\phi = U + P_0V - T_0S$, $\Delta\epsilon = \phi_2 - \phi_1$.

The stream exergy is the exergy transported by unit incoming mass. Neglecting kinetic and potential energies and using the Darrieus function[1,24] $b = h - T_0 s$, we see that the stream exergy is $b - b_0$. The irreversibility of the process is $I = T_0 \Sigma \Delta s$, where Δs is for all systems including the atmosphere. This is the Guoy-Stodola equation.[3, 15] (See also Refs. 24 and 25.) This is also called the loss of availability. If $T = T_0$ and $V = V_0$, then $\epsilon = A - A_0$, where $A = U - TS$. If $T = T_0$ and $P = P_0$, then $\epsilon = G - G_0$, where $G = H - TS$.

One example of exergy change is the heat transfer between two identical solid blocks, each of mass m and constant specific heat c. Block A is initially at temperature T_a and block B at T_b. The surrounding atmosphere is at P_0, T_0. Finally, the two temperatures become equal. The change in exergy is

$$\Delta\epsilon = -mc\,T_0 \ln\left[\frac{(T_a + T_b)^2}{4T_aT_b}\right]$$

for $T_a \neq T_b$, $\Delta\epsilon < 0$. The irreversibility I is $-\Delta\epsilon$. The exchange of heat between systems at different temperatures is irreversible, and hence there is a destruction of exergy. In a reversible process the loss in exergy is exactly equal to the useful work done. If the process is irreversible, the loss in exergy exceeds the useful work done.

The exergy of a vacuum of volume V in an atmosphere at P_0, T_0 is P_0V while that of an ideal gas at P, V, T_0 in an atmosphere at P_0, T_0 is

$$P_0V\left\{1 - \left(\frac{P}{P_0}\right)\left[1 - \ln\left(\frac{P}{P_0}\right)\right]\right\}$$

If air from an atmosphere at P_0, T_0 slowly flows into an initially exhausted insulted tank of volume V until the pressure becomes P_0, the irreversibility of the process is

$$I = \left(\frac{P_0V}{k-1}\right)\ln k$$

where $k = c_p/c_v$.

The Gibbs function is of particular importance in processes where chemical changes occur. For reversible isothermal steady-flow processes, or for reversible constant-pressure isothermal nonflow processes, change in free energy is equal to net work.

Helmholtz free energy, $f = u - Ts$, is equal to the work during a constant-volume isothermal reversible nonflow process.

All these functions g and f are point functions, and like E, h, and s their differentials are complete or perfect.

PERFECT DIFFERENTIALS. MAXWELL RELATIONS

If z is some function of x and y, in general

$$dz = \left(\frac{\partial z}{\partial x}\right)_y dx + \left(\frac{\partial z}{\partial y}\right)_x dy$$

Substituting M for $(\partial z/\partial x)_y$ and N for $(\partial z/\partial y)_x$,

$$dz = M\,dx + N\,dy$$

But $\dfrac{\partial}{\partial y}\left(\dfrac{\partial z}{\partial x}\right) = \dfrac{\partial}{\partial x}\left(\dfrac{\partial z}{\partial y}\right)$ or $\dfrac{\partial M}{\partial y} = \dfrac{\partial N}{\partial x}$. This is Euler's criterion for integrability. A perfect differential has the characteristics of dz stated above. Many important thermodynamic relations may be derived from the appropriate point function by the use of this relation; see Table 4.1.1.

From the third column of the bottom half of the table, by equating various of the terms which are equal, one may obtain

$$\left(\frac{\partial u}{\partial s}\right)_v = \left(\frac{\partial h}{\partial s}\right)_p \qquad \left(\frac{\partial u}{\partial v}\right)_s = \left(\frac{\partial f}{\partial v}\right)_T$$

$$\left(\frac{\partial h}{\partial p}\right)_s = \left(\frac{\partial g}{\partial p}\right)_T \qquad \left(\frac{\partial g}{\partial T}\right)_p = \left(\frac{\partial f}{\partial T}\right)_v$$

By mathematical manipulation of equations previously given, the following important relations may be formulated:

$$c_v = \left(\frac{\partial q}{\partial T}\right)_v = T\left(\frac{\partial s}{\partial T}\right)_v = \left(\frac{\partial u}{\partial T}\right)_v$$

$$c_p = \left(\frac{\partial q}{\partial T}\right)_p = T\left(\frac{\partial s}{\partial T}\right)_p = \left(\frac{\partial h}{\partial T}\right)_p$$

$$c_p - c_v = T\left(\frac{\partial v}{\partial T}\right)_p\left(\frac{\partial p}{\partial T}\right)_v$$

$$\left(\frac{\partial c_v}{\partial v}\right)_T = T\left(\frac{\partial^2 p}{\partial T^2}\right)_v \qquad \left(\frac{\partial c_p}{\partial T^2}\right)_p = -T\left(\frac{\partial^2 v}{\partial T^2}\right)_p$$

Table 4.1.1 Maxwell Relations

Function	Differential	Maxwell relation
$\Delta u = q + W$	$du = T\,ds - p\,dv$	$\left(\frac{\partial T}{\partial v}\right)_s = -\left(\frac{\partial p}{\partial s}\right)_v$
$h = u + pv$	$dh = T\,ds + v\,dp$	$\left(\frac{\partial T}{\partial p}\right)_s = \left(\frac{\partial v}{\partial s}\right)_p$
$f = u - Ts$	$df = -s\,dT - p\,dv$	$\left(\frac{\partial s}{\partial v}\right)_T = \left(\frac{\partial p}{\partial T}\right)_v$
$g = h - Ts$	$dg = -s\,dT + v\,dp$	$\left(\frac{\partial s}{\partial p}\right)_T = -\left(\frac{\partial v}{\partial T}\right)_p$

By holding certain variables constant, a second set of relations is obtained:

Differential	Independent variable held constant	Relation
$du = T\,ds - p\,dv$	s	$\left(\frac{\partial u}{\partial v}\right)_s = -p$
	v	$\left(\frac{\partial u}{\partial s}\right)_v = T$
$dh = T\,ds + v\,dp$	s	$\left(\frac{\partial h}{\partial p}\right)_s = v$
	p	$\left(\frac{\partial h}{\partial s}\right)_p = T$
$df = -s\,dT - p\,dv$	T	$\left(\frac{\partial f}{\partial v}\right)_T = -p$
	v	$\left(\frac{\partial f}{\partial T}\right)_v = -s$
$dg = -s\,dT + v\,dp$	T	$\left(\frac{\partial g}{\partial p}\right)_T = v$
	p	$\left(\frac{\partial g}{\partial T}\right)_p = -s$

Relations involving q, u, h, and s:

$$dq = c_v\,dT + T\left(\frac{\partial p}{\partial T}\right)_v dv = c_p\,dT - T\left(\frac{\partial v}{\partial T}\right)_p dp$$

$$du = c_v\,dT + \left[T\left(\frac{\partial p}{\partial T}\right)_v - p\right]dv$$

$$dh = c_p\,dT - \left[T\left(\frac{\partial v}{\partial T}\right)_p - v\right]dp$$

$$ds = c_v\frac{dT}{T} + \left(\frac{\partial p}{\partial T}\right)_v dv = c_p\frac{dT}{T} - \left(\frac{v}{\partial T}\right)_p dp$$

Since $q + W = du$ and $h = u + pv$, for reversible processes,

$$du = T\,ds - p\,dv \qquad \text{and} \qquad dh = du + p\,dv + v\,dp$$

it follows that

$$v = T\left(\frac{\partial s}{\partial p}\right)_T + \left(\frac{\partial h}{\partial p}\right)_T$$

But from the Maxwell relations,

$$\left(\frac{\partial v}{\partial T}\right)_p = -\left(\frac{\partial s}{\partial p}\right)_T$$

Therefore,

$$\left(\frac{\partial h}{\partial p}\right)_T = v - T\left(\frac{\partial v}{\partial T}\right)_p$$

Similarly,

$$\left(\frac{\partial u}{\partial v}\right)_T = -\left[p - T\left(\frac{\partial p}{\partial T}\right)_v\right]$$

These last two equations give in terms of p, v, and T the necessary relations that must hold for any system, however complex. An equation in p, v, and T for the properties of a substance is called an equation of state. These two equations applicable to any substance or system are known as **thermodynamic equations of state.**

Presentation of Thermal Properties Before the laws of thermodynamics can be applied and quantitative results obtained in the analysis of an engineering system, it is necessary to have available the properties of the system, some of which are temperature, pressure, internal energy entropy, and enthalpy. In general, the property of a pure substance under equilibrium conditions may be expressed as a function of two other properties. This is based on the assumption that certain effects, such as gravitational and magnetic, are not important for the condition under investigation. The various properties of a pure substance under equilibrium conditions may be expressed by an equation of state, which in general form follows:

$$p = f(T, v)$$

In this relation the pressure is shown to be a function of both the temperature and the specific volume. Many special forms of equations of state are used in the analysis of engineering systems. Plots of the properties of various pure substances are very useful in studies dealing with thermodynamics. Two-dimensional plots, such as $p - v$, $p - h$, $p - T$, $T - s$, etc., show phase relations and are important in the analysis of cycles.

The constants in the equations of state are usually based on experimental data. The properties may be presented in many different ways, some of which are:

1. As equations of state, e.g., the perfect gas laws and the van der Waals equation.
2. As charts or graphs.
3. As tables.
4. As approximations which may be useful when more reliable data are not available.

IDEAL GAS LAWS

At low pressures and high enough temperatures, in the absence of chemical reaction, all gases approach a condition such that their *P-V-T* properties may be expressed by the simple relation

$$pv = RT$$

If v is expressed as volume per unit weight, the value of the constant R will be different for different gases. If v is expressed as the volume of one molecular weight of gas, then R_u is the same for all gases in any chosen system of units. Hence $R = R_u/M$.

In general, for any amount of gas, the ideal gas equation becomes

$$pV = nMRT = nR_uT = \frac{m}{M}R_uT$$

where V is now the total gas volume, n is the number of moles of gas in the volume V, M is the molecular weight, and $R_u = MR$ the universal gas constant. An alternative ideal gas equation of state is $pv = R_uT/M$. It is different from the preceding in the use of specific volume v rather than total volume V.

For all ideal gases, $R_u = MR$ in lb · ft is 1,546. One pound mol of any perfect gas occupies a volume of 359 ft^3 at 32°F and 1 atm.

For many engineering purposes, use of the gas laws is permissible up to pressures of 100 to 200 lb/in^2 if the absolute temperatures are at least twice the critical temperatures. Below the critical temperature, errors introduced by use of the gas laws may usually be neglected up to 15 lb/in^2 pressure although errors of 5 percent are often met when dealing with saturated vapors.

The **van der Waals equation of state,** $p = BT/(v - b) - a/v^2$, is a modification of the ideal gas law which is sometimes useful at high pressures. The quantities B, a, and b are constants.

Many empirical or semiempirical equations of state have been proposed to represent the real variation of pressure with volume and temperature. The Benedict-Webb-Rubin equation is among them; see Perry, "Chemical Engineers Handbook," 8th ed., McGraw-Hill. Computer programs have been devised for the purpose; see Deutsch, "Microcomputer Programs for Chemical Engineers," McGraw-Hill. For computer programs and output for steam and other fluids, including air tables, see Irvine and Liley, "Steam and Gas Tables with Computer Programs," Academic Press.

Approximate *P-V-T* Relations For many gases, *P-V-T* data are not available. An approximation useful under such circumstances is based on the observation of van der Waals that in terms of reduced properties most gases approximate a common **reduced equation of state.** The reduced quantities are the actual ones divided by the corresponding critical quantities, e.g., the reduced temperature $T_R = T_{\text{actual}}/T_{\text{critical}}$, the reduced volume $v_R = v_{\text{actual}}/v_{\text{critical}}$, the reduced pressure $p_R = p_{\text{actual}}/p_{\text{critical}}$. The gas laws may be made to apply to any nonperfect gas by the introduction of a correction factor

$$pV = ZNR_uT$$

When the gas laws apply, $Z = 1$ and on a molal basis $Z = pV/(R_uT)$. If on a plot of Z versus p_R lines of constant T_R are drawn, for different substances these are found to fall in narrow bands. Single T_R lines may be drawn to represent approximately the various bands. This has been done in Fig. 4.1.3. To use the chart, only the critical pressure and temperature of the gas need be known.

EXAMPLE. Find the volume of 1 lb of steam at 5,500 psia and 1200°F (by steam tables, $v = 0.1516$ ft³/lb).

For water, critical temperature = 705.4°F; critical pressure = 3,206.4 psia; reduced temp = 1660/1165 = 1.43; reduced pressure = 5,500/3,206.4 = 1.72; μ (see Fig. 4.1.3) = 0.83, $v = 0.83\ (1{,}546)(1{,}660)/(18)(5{,}500)(144) = 0.149$ ft³. Error = 100(0.152–0.149)/0.152 = 1.7 percent. If the gas laws had been used, the error would have been 17 percent.

No entirely satisfactory method for calculation for gaseous mixtures has been developed, but the use of average critical constants as proposed by Kay (*Ind. Eng. Chem.,* **28,** 1936, p. 1014) is easy and gives satisfactory results under conditions considerably removed from the critical. He assumes the gaseous mixture can be treated as if it were a single pure gas with a pseudocritical pressure and temperature estimated by a method of molar averaging.

$$(T_c)_{\text{mixture}} = (T_c)_a y_a + (T_c)_b y_b + (T_c)_c y_c + \cdots$$
$$(p_c)_{\text{mixture}} = (p_c)_a y_a + (p_c)_b y_b + (p_c)_c y_c + \cdots$$

where $(T_c)_a$ is the critical temperature of pure a, etc.; $(p_c)_a$ is the critical pressure of pure a, etc.; and y_a is the mole fraction of a, etc. For a gaseous mixture made up of gases, a, b, c, etc., the pseudocritical constants having been determined, the gaseous mixture is handled on the μ charts as if it were a single pure gas.

IDEAL GAS MIXTURES

Many of the fluids involved in engineering systems are physical mixtures of the permanent gases or one or more of these with superheated or saturated vapors. For example, normal atmospheric air is a mixture of oxygen and nitrogen with traces of other gases, plus superheated or saturated water vapor, or at times saturated vapor and liquid. If the properties of each constituent of a mixture would have to be considered individually during an analysis of a system, the procedures would be very complex. Experience has demonstrated that a mixture of gases may be regarded as an equivalent gas, the properties of which depend upon the kind and proportion of each of the constituents. The general relations applicable to a mixture of perfect gases will be presented. Let V denote the total volume of the mixture, $m_1, m_2, m_3, \ldots$ the masses of the constituent gases, $R_1, R_2, R_3, \ldots$ the corresponding gas constants, and R_m the constant for the mixture. The **partial pressures** of the constituents, i.e., the pressures that the constituents would have if occupying the total volume V, are $p_1 = m_1R_1T/V$, $p_2 = m_2R_2T/V$, etc.

According to Dalton's law, the **total pressure p of the mixture** is the sum of the partial pressures; i.e., $p = p_1 + p_2 + p_3 + \cdots$. Let $m = m_1 + m_2 + m_3 + \cdots$ denote the total mass of the mixture; then $pV = mR_mT$ and $R_m = \Sigma(m_iR_i)/m$. Also $p_1/p = m_1R_1/(mR_m)$, $p_2/p = m_2R_2/(mR_m)$, etc.

Let $V_1, V_2, V_3 + \ldots$ denote the volumes that would be occupied by the constituents at pressure p and temperature T (these are given by the volume composition of the gas). Then $V = V_1 + V_2 + V_3 + \cdots$ and the apparent molecular weight m_m of the mixture is $m_m = \Sigma(m_iV_i)/V$. Then $R_m = 1{,}546/m_m$. The subscript i denotes an individual constituent.

Volume of 1 lb at 32°F and atm pressure $= 359/m_m$.

Mass of 1 ft³ at 32°F and atm pressure $= 0.002788m_m$.

The specific **heats of the mixture** are, respectively,

$$c_p = \Sigma(m_ic_{pi})/m \qquad c_v = \Sigma(m_ic_{vi})/m$$

Internal Energy, Enthalpy, and Entropy of an Ideal Gas If an ideal gas with constant specific heats changes from an initial state p_1, V_1, T_1 to a final state p_2, V_2, T_2, the following equations hold:

$$u_2 - u_1 = mc_v(T_2 - T_1) = (p_2v_2 - p_1v_1)(k - 1)$$

$$h_2 - h_1 = mc_p(T_2 - T_1) = k\frac{(p_2v_2 - p_1v_1)}{k - 1}$$

$$s_2 - s_1 = m\left(c_v \ln\frac{T_2}{T_1} + R\ln\frac{v_2}{v_1}\right)$$

$$= m\left(c_p \ln\frac{T_2}{T_1} - R\ln\frac{p_2}{p_1}\right) = m\left(c_p \ln\frac{v_2}{v_1} + c_v \ln\frac{p_2}{p_1}\right)$$

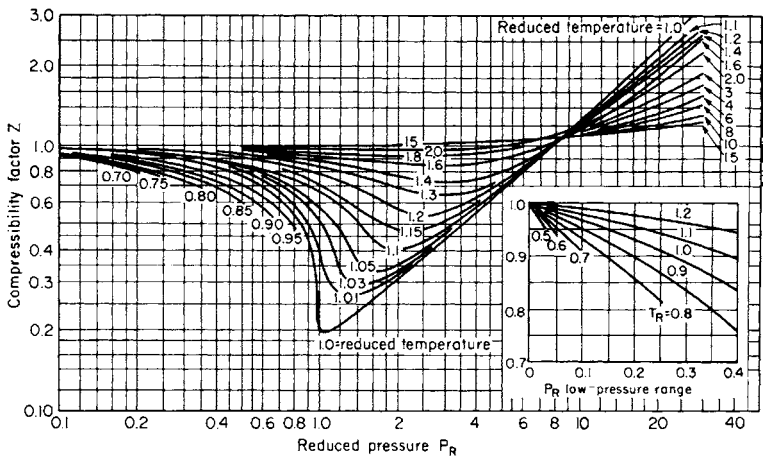

Fig. 4.1.3 Compressibility factors for gases and vapors. *(From Hougen and Watson, "Chemical Process Principles," Wiley.)*

In general, the energy per unit mass is $u = c_v T + u_0$, the enthalpy is $h = c_p T + h_0$, and the entropy is $s = c_v \ln T + R \ln v + s_0 = c_p \ln T - R \ln p + s_0' = c_p \ln v + c_p \ln p = s_0''$.

The two fundamental equations for ideal gases are

$$dq = c_v\,dT + p\,dv \qquad dq = c_p\,dT - v\,dp$$

SPECIAL CHANGES OF STATE FOR IDEAL GASES

(Specific heats assumed constant)

In the following formulas, the subscripts 1 and 2 refer to the initial and final states, respectively.

1. *Constant volume:* $p_2/p_1 = T_2/T_1$.

$$Q_{12} = U_2 - U_1 = mc_v(t_2 - t_1) = V(p_2 - p_1)/(k - 1)$$
$$W_{12} = 0 \qquad s_2 - s_1 = mc_v \ln (T_2/T_1)$$

2. *Constant pressure:* $V_2/V_1 = T_2/T_1$.

$$W_{12} = -p(V_2 - V_1) = -mR(t_2 - t_1)$$
$$Q_{12} = mc_p(t_2 - t_1) = kW_{12}/(k - 1)$$
$$s_2 - s_1 = mc_p \ln (T_2/T_1)$$

3. *Isothermal (constant temperature):* $p_2/p_1 = V_1/V_2$.

$$U_2 - U_1 = 0 \qquad W_{12} = -mRT \ln (V_2/V_1) = -p_1V_1 \ln (V_2/V_1)$$
$$Q_{12} = -W_{12} \qquad s_2 - s_1 = Q_{12}/T = mR \ln (V_2/V_1)$$

4. *Reversible adiabatic, isentropic:* $p_1V_1^k = p_2V_2^k$.

$$T_2/T_1 = (V_1/V_2)^{k-1} = (p_2/p_1)^{(k-1)/k}$$
$$W_{12} = U_1 - U_2 = mc_v(t_1 - t_2)$$
$$Q_{12} = 0 \qquad s_2 - s_1 = 0$$
$$W_{12} = (p_2V_2 - p_1V_1)/(k - 1)$$
$$= -p_1V_1[(p_2/p_1)^{(k-1)/k} - 1]/(k - 1)$$

5. *Polytropic:* This name is given to the change of state which is represented by the equation $pV^n = \text{const}$. A polytropic curve usually represents actual expansion and compression curves in motors and air compressors for pressures up to a few hundred pounds. By giving n different values and assuming specific heats constant, the preceding changes may be made special cases of the polytropic change, thus,

For $n = 1$,	$pv = \text{const}$	isothermal
$n = k$,	$pv^k = \text{const}$	isentropic
$n = 0$,	$p = \text{const}$	constant pressure
$n = \infty$,	$v = \text{const}$	constant volume

For a polytropic change of an ideal gas (for which c_v is constant), the specific heat is given by the relation $c_n = c_v(n - k)(n - 1)$; hence for $1 < n < k$, c_n is negative. This is approximately the case in air compression up to a few hundred pounds pressure. The following are the principal formulas:

$$p_1V_1^n = p_2V_2^n$$
$$T_2/T_1 = (V_1/V_2)^{n-1} = (p_2/p_1)^{(n-1)/n}$$
$$W_{12} = (p_2V_2 - p_1V_1)/(n - 1)$$
$$= -p_1V_1[(p_2/p_1)^{(n-1)/n} - 1]/(n - 1)$$
$$Q_{12} = mc_n(t_2 - t_1)$$
$$W_{12} : U_2 - U_1 : Q_{12} = k - 1 : 1 - n : k - n$$

The quantity $(p_2/p_1)^{(k-1)/k} - 1$ occurs frequently in calculations for perfect gases.

Determination of Exponent *n* If two representative points (p_1, V_1 and p_2, V_2) be chosen, then

$$n = (\log p_1 - \log p_2)/(\log V_2 - \log V_1)$$

Several pairs of points should be used to test the constancy of n.

Changes of State with Variable Specific Heat In case of a considerable range of temperature, the assumption of constant specific heat is not permissible, and the equations referring to changes of state must be suitably modified. (This statement does not apply to inert or monatomic gases.) Experiments on the specific heat of various gases show that the specific heat may sometimes be taken as a linear function of the temperature: thus, $c_v = a + bT$; $c_p = a' + b'T$. In that case, the following expressions apply for the change of internal energy and entropy, respectively:

$$U_2 - U_1 = m[a(T_2 - T_1 + 0.5b(T_2^2 - T_1^2)]$$
$$S_2 - S_1 = m[a \ln (T_2/T_1) + b(T_2 - T_1) + R \ln (V_2/V_1)]$$

and for an isentropic change,

$$W_{12} = U_2 - U_1$$
$$R \ln (V_1/V_2) = a \ln (T_2/T_1) + b(T_2 - T_1)$$

GRAPHICAL REPRESENTATION

The change of state of a substance may be shown graphically by taking any two of the six variables p, V, T, S, U, H as independent coordinates and drawing a curve to represent the successive values of these two variables as the change proceeds. While any pair may be chosen, there are three systems of graphical representation that are specially useful.

1. p and V. The curve (Fig. 4.1.4) represents the simultaneous values of p and V during the change (reversible) from state 1 to state 2. The

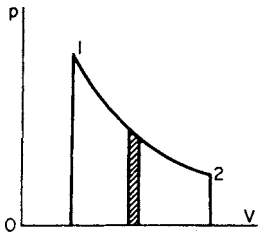

Fig. 4.1.4

area between the curve and the axis OV is given by the integral $\int_{v_1}^{v_2} p\,dV$ and therefore represents the external work W_{12} done by the gas during the change. The area included by a closed cycle represents the work of the cycle (as in the indicator diagram of the steam engine).

2. T and S (Fig. 4.1.5). The absolute temperature T is taken as the ordinate, the entropy S as the abscissa. The area between the curve of change of state and the S axis is given by the integral $\int_{S_1}^{S_2} T\,dS$, and it therefore represents the heat Q_{12} absorbed by the substance from external sources provided there are no irreversible effects. On the T-S diagram, an isothermal is a straight line, as AB, parallel to the S axis; a *reversible* adiabatic is a straight line, as CD, parallel to the T axis.

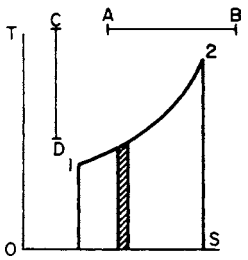

Fig. 4.1.5

In the case of internal generation of heat through friction, as in steam turbines, the increase of entropy is given by $\int_{T_1}^{T_2} (dQ'/T)$ and the area under the curve represents the heat Q' thus generated. In this case, an adiabatic is *not* a straight line parallel to the T axis.

3. *H* and *S*. In the system of representation devised by Dr. Mollier, the enthalpy *H* is taken as the ordinate and the entropy *S* as the abscissa. If on this diagram (Fig. 4.1.6) a line of constant pressure, as 12, be drawn, the heat absorbed during the change at consiant pressure is given by $Q_{12} = H_2 - H_1$, and this is represented by the line segment 23. The **Mollier diagram** is specially useful in problems that involve the flow of fluids, throttling, and the action of steam in turbines.

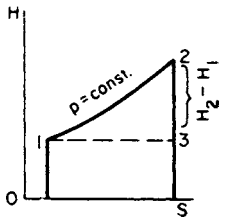

Fig. 4.1.6

IDEAL CYCLES WITH PERFECT GASES

Gases are used as heat mediums in several important types of machines. In air compressors, air engines, and air refrigerating machines, atmospheric air is the medium. In the internal-combustion engine, the medium is a mixture of products of combustion. Engines using gases are operated in certain well-defined cycles, which are described below. In the analyses given, ideal conditions that cannot be attained by actual motors are assumed. However, conclusions derived from such analyses are usually approximately valid for the modified actual cycle.

In the following, the subscripts 1, 2, 3, etc., refer to corresponding points shown in the figures. The work of the cycle is denoted by *W* and the net heat absorbed by *Q*.

Carnot Cycle The Carnot cycle (Fig. 4.1.7) is of historic interest. It consists of two isothermals and two isentropics. The heat absorbed

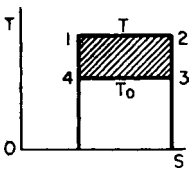

Fig. 4.1.7 Carnot cycle.

along the upper isothermal 12 is $Q_{12} = mRT \ln(V_2/V_1)$, and the heat transformed into work, represented by the cycle area, is $W = Q_{12}(1 - T_0/T)$.

$$W = -mR(T - T_0)\ln\left(\frac{V_2}{V_1}\right)$$

If the cycle is traversed in the reverse sense, $Q_{43} = mRT_0 \ln (V_3/V_4)$ is the heat absorbed from the cold body (brine), and the ratio $Q_{43} : (W) = T_0 : (T - T_0)$ is the **coefficient of performance** of the refrigerating machine.

Leff (*Amer. J. Phys.,* **55,** no. 7, 1987, pp. 602–610) showed that the **thermal efficiency** of a heat engine producing the maximum possible work per cycle consistent with its operating temperature range resulted in efficiencies equal to or well approximated by $\eta = 1 - \sqrt{T_c/T_h}$, where c = cold and h = hot, as found by Curzon and Ahlborn (*Amer. J. Phys.,* **43,** no. 1, 1975, pp. 22–24) for maximum power output. If the work output per cycle is kept fixed, the thermal efficiency can be increased by operating the heat engine at less than maximum work output per cycle, the limit being an engine of infinite size having a Carnot efficiency. Leff's paper considers Otto, Brayton-Joule, Diesel, and Atkinson cycles. Figure 4.1.8 illustrates the difference between maximum power and maximum efficiency. Detailed discussion of **finite time thermodynamics** appears in Sieniutcyz and Salamon, "Finite Time Thermodynamics and Thermoeconomies," *Advan. Thermo.,* **4,** 306 pp., 1990, Taylor & Francis, London.

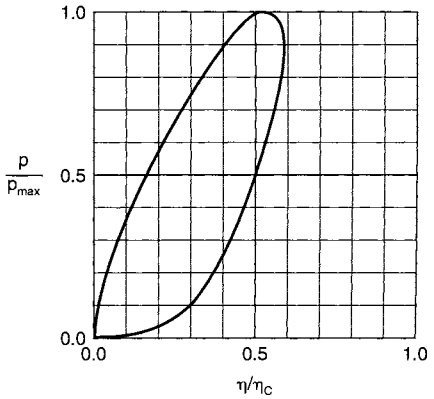

Fig. 4.1.8 Ratio of actual power to maximum power as a function of ratio of actual thermal efficiency to Carnot efficiency.

Finite time thermodynamics is a term applied to the consideration that, for any finite energy transfer, a finite time must occur. A common statement in the literature is that the analysis started from the work of Curzon and Ahlborn (*Amer. J. Phys.,* **43,** 1975, pp. 22–24). According to Bejan (*Amer. J. Phys.,* **62,** no. 1, Jan. 1994, pp. 11–12), this statement is not true, and the original analysis was by Novikov (*At. Energy,* **3,** 1957, p. 409, and *Nucl. Energy,* pt. II, **7,** 1958, pp. 125–148). Wu (*Energy Convsn. Mgmt.,* **34,** no. 12, 1993, pp. 1239–1247) discusses the *endoreversible Carnot heat engine* being one in which all the losses are associated with the transfer of heat to and from the engine, there being no internal losses within the engine itself and refers to Wu and Kiang (*Trans. J. Eng. Gas Turbines & Power,* **113,** 1991, p. 501) for a detailed literature survey.

Otto and Diesel Cycles The ideal cycles usually employed for internal-combustion engines may be classified in two groups: (1) explosive—Otto (the fluid is introduced in gaseous form), (2) nonexplosive—Diesel, Joule (the fluid is introduced in liquid form).

Otto Cycle (Fig. 4.1.9 for pressure-volume plane, Fig. 4.1.10 for temperature-entropy plane) Isentropic compression 12 is followed by ignition and rapid heating at constant volume 23. This is followed by isentropic expansion, 34. Assuming constant specific heats the following relations hold:

$$\frac{T_2}{T_1} = \frac{T_3}{T_4} = \left(\frac{p_2}{p_1}\right)^{k-1/k} = \left(\frac{p_3}{p_4}\right)^{k-1/k} = \left(\frac{V_1}{V_2}\right)^{k-1}$$

$$Q_{23} = mc_v(T_1 - T_2)$$

$$W = Q_{23}[1 - (T_1/T_2)] = mc_v(T_3 - T_4 - T_2 + T_1)$$

$$\text{Efficiency} = 1 - \frac{T_1}{T_2} = 1 - \left(\frac{V_2}{V_1}\right)^{k-1} = 1 - \left(\frac{p_1}{p_2}\right)^{(k-1)/k}$$

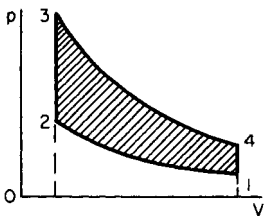

Fig. 4.1.9 Otto cycle.

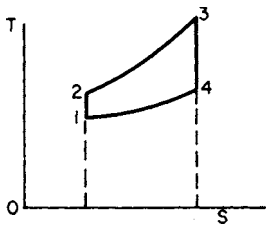

Fig. 4.1.10 Otto cycle.

If the compression and expansion curves are polytropics with the same value of n, replace k by n in the first relation above. In this case,

$$W = [(p_3V_3 - p_4V_4) - (p_2V_2 - p_1V_1)]/(n - 1)$$
$$= mR(T_3 - T_4 - T_2 + T_1)/(n - 1)$$

The **mean effective pressure** of the diagram is given by

$$p_m = ap_1(p_3/p_2 - 1)$$

where a has the values given in the following table.

	$p_2/p_1 = 3$	4	5	6	8	10	12	14	16
($n = 1.4$)	$a = 1.70$	1.94	2.13	2.31	2.62	2.88	3.10	3.31	3.50
($n = 1.3$)	$a = 1.69$	1.92	2.11	2.28	2.57	2.81	3.03	3.22	3.39
($n = 1.2$)	$a = 1.68$	1.90	2.08	2.25	2.51	2.74	2.94	3.12	3.27

A later paper by Wu and Blank (*Energy Convsn. Mgmt.,* **34,** no. 12, 1993, pp. 1255–1269) considered optimization of the endoreversible Otto cycle with respect to both power and mean effective pressure.

Diesel Cycle In the diesel oil engine, air is compressed to a high pressure. Fuel is then injected into the air, which is at a temperature above the ignition point, and it burns at nearly constant pressure (23, in Fig. 4.1.11). Isentropic expansion of the products of combustion is followed by exhaust and suction of fresh air, as in the Otto cycle.

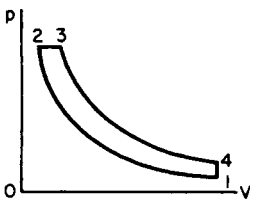

Fig. 4.1.11 Diesel cycle.

The work obtained is

$$W = m[c_p(T_3 - T_2) - c_v(T_4 - T_1)]$$

and the efficiency of the ideal cycle is

$$1 - [(T_4 - T_1)/k(T_3 - T_2)]$$

The **Joule cycle,** also called the **Brayton cycle** (Fig. 4.1.12), consists of two isentropics and two constant-pressure lines. The following relations hold:

$$V_3/V_2 = V_4/V_1 = T_3/T_2 = T_4/T_1$$
$$\frac{T_2}{T_1} = \frac{T_3}{T_4} = \left(\frac{V_1}{V_2}\right)^{k-1} = \left(\frac{V_4}{V_3}\right)^{k-1} = \left(\frac{p_2}{p_1}\right)^{k-1/k}$$
$$W = mc_p(T_3 - T_2 - T_4 + T_1)$$
$$\text{Efficiency} = W/Q_{23} = 1 - T_1/T_2$$

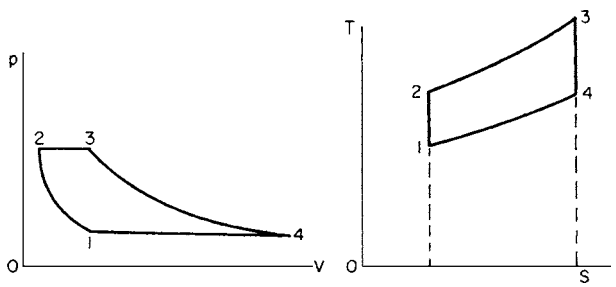

Fig. 4.1.12 Joule or Brayton cycle.

The Joule cycle has assumed renewed importance as a basis for analysis of gas turbine operation.

For additional information on internal combustion engines, see Campbell, "Thermodynamic Analysis of Internal Combustion Engines," Wiley; Taylor, "The Internal Combustion Engine in Theory and Practice," MIT Press. New designs for internal-combustion engines were reviewed by Wallace (*Sci. Progr., Oxford,* **75,** 1991, pp. 15–32).

Stirling Cycle The Stirling engine may be visualized as a cylinder with a piston at each end. Between the pistons is a regenerator. The cylinder is assumed to be insulated except for a contact with a hot reservoir at one end and a contact with a cold reservoir at the other end.

Starting with state 1, Fig. 4.1.13, heat from the hot reservoir is added to the gas at T_H (or $T_H - dT$). During the reversible isothermal process, the left piston moves outward, doing work as the system volume increases and the pressure falls. Both pistons are then moved to the right at the same rate to keep the system volume constant (process 2–3). No heat transfer occurs with either reservoir. As the gas passes through the regenerator, heat is transferred from the gas to the regenerator, causing the gas temperature to fall to T_L by the time the gas leaves the right end of the regenerator. For this heat-transfer process to be reversible, the temperature of the regenerator at each point must equal the gas temperature at that point. Hence there is a temperature gradient through the regenerator from T_H at the left end to T_L at the right end. No work is accomplished during this process. During the path 3–4, heat is removed from the gas at T_L (or $T_L + dT$) to the reservoir at T_L. To hold the gas temperature constant, the right piston is moved inward—doing work on the gas with a resulting increase in pressure. During process 4–1, both pistons are moved to the left at the same rate to keep the system volume constant. The pistons are closer together during this process than they were during process 2–3, since $V_4 = V_1 < V_2 = V_3$. No heat is transferred to either reservoir. As the gas passes back through the re-generator, the energy stored in the regenerator during 2–3 is returned to the gas. The gas emerges from the left end of the regenerator at the tempe rature T_H. No work is performed during this process since the volume remains constant. Thus the cycle is completed and is externally reversible. The system exchanges a net amount of heat with only the two energy reservoirs T_H and T_L. Two types of Stirling engines are shown in Fig. 4.1.14. Extensive research-and-development effort has been devoted to the Stirling engines for future use as prime movers in space power systems operating on solar energy. (See also Sec. 9.6.)

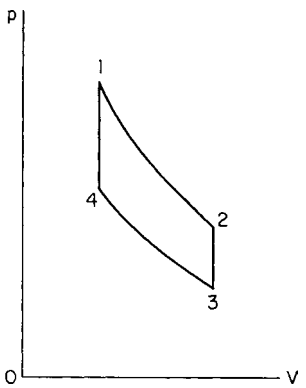

Fig. 4.1.13 Stirling cycle.

More information can be found in Meijer, *De Ingenieur,* **81,** nos. 18 and 19, 1969; Reader and Hooper, "Stirling Engines," Spon, London; Sternlicht, *Chem. Tech.,* **13,** 1983, pp. 28–36; Walker, "Stirling Engines," Oxford Univ. Press.

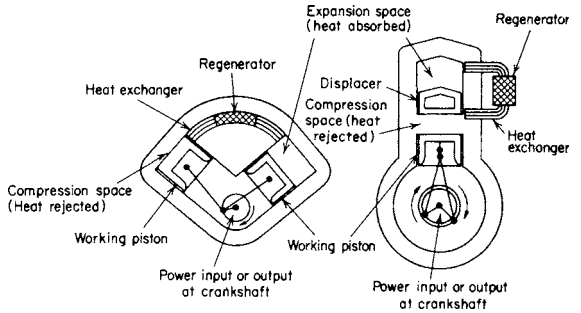

Fig. 4.1.14 Two main types of Stirling engine: (1) left, double-cylinder two piston; (2) right, single-cylinder, piston plus displacer. Each has two variable-volume working spaces filled with the working fluid—one for expansion and one for compression of the gas. Spaces are at different temperatures—the extreme temperatures of the working cycle—and are connected by a duct, which holds the regenerators and heat exchangers. (*Intl. Science and Technology,* May 1962.)

AIR COMPRESSION

It is assumed that the compressor works under ideal reversible conditions without clearance and without friction losses and that the changes are over ranges where the gas laws are applicable. Where the gas laws cannot be used, analysis in terms of Z charts is convenient. If the compression from p_1 to p_2 (Fig. 4.1.15) follows the law $pV^n = \text{const}$, the work represented by the indicator diagram is

$$W = n(p_2V_2 - p_1V_1)/(n-1)$$
$$= np_1V_1[(p_2/p_1)^{(n-1)/n} - 1]/(n-1)$$

The temperature at the end of compression is given by $T_2/T_1 = (p_2/p_1)^{(n-1)/n}$. The work W is smaller the smaller the value on n, and the purpose of the water jackets is to reduce n from the isentropic value 1.4. Under usual working conditions, n is about 1.3.

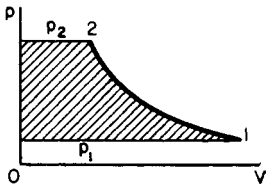

Fig. 4.1.15 Air compressor cycle.

When the pressure p_2 is high, it is advantageous to divide the process into two or more stages and cool the air between the cylinders. The saving effected is best shown on the T-S plane (Fig. 4.1.16). With single-stage compression, 12 represents the compression from p_1 to p_2, and if the constant-pressure line 23 is drawn cutting the isothermal through point 1 in point 3, the area $1'1233'$ represents the work W. When two stages are used, 14 represents the compression from p_1 to an intermediate pressure p', 45 cooling at constant pressure in the intercooler between the cylinders, and 56 the compression in the second stage. The area under 14563 represents the work of the two stages and the area 2456 the saving effected by compounding. This saving is a maximum when $T_4 = T_6$, and this is the case when the intermediate pressure p' is given by $p' = \sqrt{p_1p_2}$ (see Sec. 14.3).

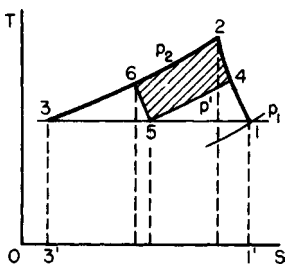

Fig. 4.1.16 Air compressor cycle

The total work in two-stage compression is

$$np_1V_1[(p'/p_1)^{(n-1)/n} + (p_2/p')^{(n-1)/n} - 2]/(n-1)$$

Gas Turbine The Brayton cycle, also called the Joule or constant pressure cycle, employs an air engine, a compressor, and a combustion chamber. Air enters the compressor wherein the pressure is increased. Fuel burning in the combustion chamber raises the temperature of the compressed air under constant-pressure conditions. The resulting high-temperature gases are then introduced to the engine where they expand and perform work. The excess work of the engine over that required to compress the air is available for operating other devices, such as a generator.

Basically, the simple gas-turbine cycle is the same as the Brayton cycle, except that the air compressor and engine are replaced by an axial flow compressor and gas turbine. Air is compressed in the compressor, after which it enters a combustion chamber where the temperature is increased while the pressure remain constant. The resulting high-temperature air then enters the turbine, thereby performing work.

Boyce ("Gas Turbine Engineering Handbook," Gulf) gives numerous examples of ideal and actual gas-turbine cycles. The graphs in this source as well as in a review by Dharmadhikari (*Chemical Engineer* (*London*), Feb. 1989, pp. 16–20) show the same relation between work output and thermal efficiency as the general graph of Gordon (*Amer. J. Phys.,* **59,** no. 6, 1991, pp. 551–555). MacDonald (ASME Paper 89-GT-103, Toronto Gas Turbine Exposition, 1989) describes the increasing use of heat exchangers in gas-turbine plants and reviews the use of recuperators (i.e., regenerators) (in *Heat Recovery Systs. & CHP.* **10,** no. 1, 1990, pp. 1–30). Gas turbines as the topping cycle with steam in the bottoming cycle were described by Huang (ASME Paper 91-GT-186 and *J. Eng. Gas Turbines & Power,* **112,** Jan. 1990, pp. 117–121) and by Cerri (*Trans. ASME,* **109,** Jan. 1987, pp. 46–54). The use of steam injection in gas-turbine cycles has received renewed attention; see, e.g., Consonni (45th Congr. Nat. Assoc. Termotechnica Ital., **IIID,** 1990, pp. 49–60), Ediss (City Univ. London Conf. Paper, Nov. 1991), Lundberg (*ASME Cogen-Turbo IGTI,* **6,** 1991, pp. 9–18). Fraize and Kinney (*J. Eng. Power,* **101,** 1979, pp. 217–227), and Larson and Williams (*J. Eng. Gas Turbines & Power,* **109,** Jan. 1987, pp. 55–63).

Analysis of closed-cycle gas-turbine plant for maximum and zero power output and for maximum efficiency was made by Woods et al. (*Proc. Inst. Mech. Eng.,* **205A,** 1991, pp. 59–66). See also pp. 287–291 and ibid., **206A,** 1992, pp. 283–288. A series of papers by Najjar appeared in *Int. J. M. E. Educ.* (**15,** no. 4, 1987, pp. 267–286); *High Temp. Technol.* (**8,** no. 4, 1990, pp. 283–289); *Heat Recovery Systems & CHP* (**6,** no. 4, 1986, pp. 323–334). For more detailed information regarding the actual gas-turbine cycles see Sec. 9.

VAPORS

General Characteristics of Vapors Let a gas be compressed at constant temperature; then, provided this temperature does not exceed a certain critical value, the gas begins to liquefy at a definite pressure, which depends upon the temperature. At the beginning of liquefaction, a unit mass of gas will also have a definite volume v_g, depending on the temperature. In Fig. 4.1.17, AB represents the compression and the

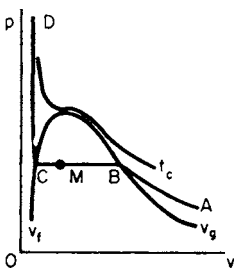

Fig. 4.1.17

point B gives the **saturation** pressure and volume. If the compression is continued, the pressure remains constant with the temperature, as indicated by BC, until at C the substance is in the liquid state with the volume v_f.

The curves v_f and v_g giving the volumes for various temperatures at the end and beginning of liquefaction, respectively, may be called the **limit curves.** A point B on curve v_g represents the state of **saturated vapor;** a point C on the curve v_f represents the saturated liquid state; and a point M between B and C represents a mixture of vapor and liquid of which the part $x = MC/BC$ is vapor and the part $1 - x = BM/BC$ is liquid. The ratio x is called the **quality of the mixture.** The region between the curves v_f and v_g is thus the region of liquid and vapor mixtures. The region to the right of curve v_g is the region of **superheated vapor.** The curve v_g dividing these regions represents the so-called **saturated vapor.**

For saturated vapor, saturated liquid, or a mixture of vapor and liquid, the pressure is a function of the temperature only, and the volume of the mixture depends upon the temperature and quality x. That is, $p = f(t)$, $v = F(t, x)$.

For the vapor in the superheated state, the volume depends on pressure and temperature [$v = F(p, t)$], and these may be varied independently.

Critical State If the temperature of the gas lies above a definite temperature t_c called the **critical temperature,** the gas cannot be liquefied by compression alone. The saturation pressure corresponding to t_c is the **critical pressure** and is denoted by p_c. At the critical states, the limit curves v_f and v_g merge; hence for temperatures above t_c, it is impossible to have a mixture of vapor and liquid. Table 4.2.21 gives the critical data for various gases; also the boiling temperature t_b corresponding to atmospheric pressure. Study of the critical region is becoming a specialized topic. NBS Misc. Publ. 273, 1966, contains 33 papers on phenomena near critical points. The ASME symposia on thermophysical properties proceedings contain numerous papers on the subject.

Vapor Pressures At a specified temperature, a pure liquid can exist in equilibrium contact with its vapor at but one pressure, its vapor pressure. A plot of these pressures against the corresponding temperatures is known as a vapor pressure curve. As noted by Martin, "Thermodynamic and Transport Properties of Gases, Liquids and Solids," ASME, New York, p. 112, the true shape of a log vapor pressure versus reciprocal absolute temperature curve is an S shape. But if the curvature (often slight) is neglected, the equation of the curve becomes $\ln P = A + B/T$. In terms of any two pairs of values (P_1, T_1), (P_2, T_2), $A = (T_2 \ln P_2 - T_1 \ln P_1)/(T_2 - T_1)$ and $B = T_1T_2/(T_2 - T_1) \ln (P_1/P_2)$. (Note that B is always negative.) Once the values of A and B have been determined, the equation can be used to determine P_3 at $T = T_3$ or T_3 at $P = P_3$. Algebraically, A and B can be eliminated to yield $\ln (P_3/P_1) = [T_2(T_3 - T_1)/T_3(T_2 - T_1)] \ln (P_2/P_1)$, and at any temperature T the slope of the vapor pressure curve is $dP/dT = (1/T^2)[T_1T_2/(T_1 - T_2)] \ln (P_2/P_1)$.

A classic survey of equations for estimating vapor pressures was given by Miller in *Ind. Eng. Chem.,* **56,** 1964, pp. 46–57. The comprehensive tables of Stull in *Ind. Eng. Chem.,* **39,** 1947, pp. 517–550, are useful though slightly dated. Table 4.2.24 gives T(K) for various P(bar) for 50 substances; P(bar) tables for various T(K) for 16 elements are given in Table 4.2.29. Boublik et al., "The Vapor Pressure of Pure Substances," Elsevier, presents an extensive collection of data.

THERMAL PROPERTIES OF SATURATED VAPORS AND OF VAPOR AND LIQUID MIXTURES

Notation

v_f, v_g = specific volume of 1 lb of saturated liquid and vapor, respectively
c_f, c_g = specific heat of saturated liquid and vapor, respectively
h_f, h_g = specific enthalpy of saturated liquid and vapor, respectively
u_f, u_g = specific internal energy of saturated liquid and vapor, respectively
s_f, s_g = specific entropy of saturated liquid and vapor, respectively
$v_{fg} = vg - v_f$ = increase of volume during vaporization
$h_{fg} = h_g - h_f$ = heat of vaporization, or heat required to vaporize a unit mass of liquid at constant pressure and temperature

Note that r may be used for h_{fg} when several heats of vaporization (as r_1, r_2, r_3, etc.) are under consideration.

$u_{fh} = u - u_f$ = increase of internal energy during vaporization
$s_{fg} = s_g - s_f = h_{fg}/T$ = increase of entropy during vaporization
pv_{fg} = work performed during vaporization

The energy equation applied to the vaporization process is

$$h_{fg} = u_{fg} + pv_{fg}$$

The properties of a unit mass of a mixture of liquid and vapor of quality x are given by the following expressions:

$$\begin{aligned} v &= v_f + xv_{fg} \\ h &= h_f + xh_{fg} \\ u &= u_f + xu_{fg} \\ s &= s_f + xs_{fg} \end{aligned}$$

Any property ψ can be expressed as a function of the property of the saturated liquid, ψ_f, that of the saturated vapor, ψ_g, and the quality x by three entirely equivalent equations:

$$\begin{aligned} \psi &= (1 - x)\psi_f + x\psi_g \\ &= \psi_f + x\psi_{fg} \\ &= \psi_g - (1 - x)\psi_{fg} \end{aligned}$$

where $\psi_{fg} = \psi_g - \psi_f$. Tables of superheated vapor usually give values of v, h, and s per unit mass. If not tabulated, the internal energy u per unit mass can be found from the equation

$$u = h - pv$$

CHARTS FOR SATURATED AND SUPERHEATED VAPORS

Certain properties of vapor mixtures and superheated vapors may be shown graphically by means of charts. Such charts show the behavior of vapors and have a practical application in the solution of certain problems.

Temperature-Entropy Chart Figures 4.2.10 and 4.2.11 show the temperature-entropy chart for water vapor. The liquid curve is obtained by plotting corresponding values of T and s_f, and the saturation curve by plotting values of T and s_g. The values are taken from Tables 4.2.17 to 4.2.20. The two curves merge into each other at the critical temperature $T = 1{,}165.4°\text{R}$ (647 K). Between these two curves, constant pressure lines are also lines of constant temperature; but at the saturation curve the constant pressure lines show a sharp break with rising temperature. The constant quality lines $x = 0.2, 0.4$, etc., are equally spaced between the liquid and saturation curves.

Figure 4.2.1 is a temperature-entropy chart for air.

Enthalpy-Entropy Chart (Mollier Chart) In this chart, the enthalpy h is taken as the ordinate and the entropy s as the abscissa.

Enthalpy–Log Pressure Chart Previously, a chart with coordinates of enthalpy and pressure was termed a pressure-enthalpy chart. In this edition these charts are called enthalpy–log pressure charts, to more correctly identify the scale plotted for pressure. This follows modern usage. Charts with pressure per se as a coordinate have a greatly different scale and appearance.

For examples of the enthalpy–log-pressure chart, see Sec. 4.2. For enthalpy–log-pressure charts for various fluids, see "Engineering Data Book," 9th ed., Gas Processors Suppliers Assoc., Tulsa, OK; Reynolds, "Thermodynamic Properties in SI," Mech. Eng. Stanford Univ. Publication.

The energy-temperature diagram reported by Bucher (*Amer. J. Phys.,* **54,** 1986, pp. 850–851) for reversible cycles and by Wallingford (*Amer. J. Phys.,* **57,** 1989, pp. 379–381) for irreversible cycles was claimed by

Bejan (*Amer. J. Phys.,* **62,** no. 1, Jan. 1994, pp. 11–12) to have been first reported at an earlier date (Bejan, *Mech. Eng. News,* May 1977, pp. 26–28).

CHANGES OF STATE. SUPERHEATED VAPORS AND MIXTURES OF LIQUID AND VAPOR

Isothermal In the only important cases, the fluid is a mixture of liquid and vapor in both initial and final states.

$$t = \text{const} \qquad p = \text{const}$$
$$x_1, x_2 = \text{initial and final qualities}$$
$$Q_{12} = mh_{fg}(x_2 - x_1)$$
$$W_{12} = mpv_{fg}(x_2 - x_1)$$
$$U_2 - U_1 = mu_{fg}(x_2 - x_1)$$
$$S_2 - S_1 = Q_{12}/T$$

Constant Pressure If the fluid is a mixture at the beginning and end of the change, the constant pressure change is also isothermal. If the initial state is in the mixture region and the final state is that of a superheated vapor, the following are the equations for Q_{12}, etc. Let h_2, u_2, v_2, and s_2 be the properties of 1 lb of superheated vapor in the final state 2; then

$$Q_{12} = m(h_2 - h_1)$$
$$U_2 - U_1 = m(u_2 - u_1)$$
$$S_2 - S_1 = m(s_2 - s_1)$$
$$W_{12} = -mp(v_2 - v_1)$$
$$h_1 = h_{f1} + x_1 h_{fg1}$$
$$u_1 = u_{f1} + x_1 u_{fg1}$$
$$s = s_{f1} + x_1 s_{fg1}$$
$$v_1 = v_{f1} + x_1 v_{fg1}$$

Constant Volume Since v_f the liquid volume is nearly constant,

$$x_1 v_{fg1} = x_2 v_{fg2}$$
$$x_2 = x_1 v_{fg1}/v_{fg2} \quad \text{or} \quad x_2 = x_1 v_{g1}/v_{g2} \quad \text{approx}$$
$$Q_{12} = U_2 - U_1 = m(u_2 - u_1) \qquad W_{12} = 0$$

Isentropic $s = \text{const}$. If the fluid is a mixture in the initial and final states,

$$s_{f1} + x_1 s_{fg1} = s_{f2} + x_2 s_{fg2}$$

If the initial state is that of superheated vapor,

$$s_1 + s_{f2} + x_2 s_{fg2}$$

in which s_1 is read from the table of superheated vapor. The final value x_2 is determined from one of these equations, and the final internal energy u_2 is then

$$u_{f2} + x_2 u_{fg2} \qquad Q_{12} = 0 \qquad W_{12} = U_2 - U_1 = m(u_2 - u_1)$$

For water vapor, the relation between p and v during an isentropic change may be represented approximately by the equation $pv^n = \text{constant}$. The exponent n is not constant, but varies with the initial quality and initial pressure, as shown in Table 4.1.2.

The isentropic expansion of superheated steam is fairly represented by $pv^n = \text{const}$, with $n = 1.315$.

The volume at the end of expansion (or compression) is $V_2 = V_1(p_1/p_2)^{1/n}$, and the external work is

$$W_{12} = (p_2V_2 - p_1V_1)/(n - 1)$$
$$= -p_1V_1[1 - (p_2/p_1)^{(n-1)/n}]/(n - 1)$$

If the initial state is in the region of superheat and final state in the mixture region, two values of n must be used: $n = 1.315$ for the expansion to the state of saturation, and the appropriate value from the first row of Table 4.1.2 for the expansion of the mixture.

MIXTURES OF AIR AND WATER VAPOR

Atmospheric Humidity The atmosphere is a mixture of air and water vapor. Dalton's law of partial pressures (for the mixture) and the ideal gas law (for each constituent) may safely be assumed to apply. The **total pressure** p_t (barometric pressure) is the sum of the **vapor pressure** p_v and the **air pressure** p_a.

The temperature of the atmosphere, as indicated by an ordinary thermometer, is the **dry-bulb temperature** t_d. If the atmosphere is cooled under constant total pressure, the partial pressures remain constant until a temperature is reached at which condensation of vapor begins. This temperature is the **dew point** t_c (condensation temperature) and is the saturation temperature, or boiling point, corresponding to the actual vapor pressure p_v. If a thermometer bulb is covered with absorbent material, e.g., linen, wet with distilled water and exposed to the atmosphere, evaporation will cool the water and the thermometer bulb to the **wet-bulb temperature** t_w. This is the temperature given by a psychrometer. The wet-bulb temperature lies between the dry-bulb temperature and the dew point. These three temperatures are distinct except for a saturated atmosphere, for which they are identical. For each of these temperatures, there is a corresponding vapor pressure. The actual vapor pressure p_v corresponds with the dew point t_c. The vapor pressures p_d and p_w, corresponding with t_d and t_w, do not represent pressures actually appearing in the atmosphere but are used in computations.

Relative humidity r is the ratio of the actual vapor pressure to the pressure of saturated vapor at the prevailing dry-bulb temperature $r = p_v/p_d$. Within the limits of usual accuracy, this equals the ratio of actual vapor density to the density of saturated vapor at dry-bulb temperature, $r = p_v/p_d$. It is to be noted that relative humidity is a property of the vapor alone; it has nothing to do with the fact that the vapor is mixed with air. It is a method of expressing the departure of the vapor from saturation. (See "ASHRAE Handbook" for information on industrial applications of relative humidity.)

Molal humidity f is the mass of water vapor in mols per 1 mol of air. The laws of Dalton and Avogadro state that the molal composition of a mixture is proportional to the distribution of partial pressures. or $f = p_v/p_a = p_v/(p_t - P_v)$.

Specific humidity (humidity ratio) W is the mass of water vapor (pounds or grains) per pound of dry air. Mass in pounds equals mass in moles multiplied by the molecular weight. The molecular weight of water is 18, and the equivalent molecular weight of air is 28.97. The ratio 28.97/18 = 1.608, or 1.61 with ample accuracy. Thus $W = f/1.61$.

Air density ρ_a is the pounds of air in one cubic foot. **Vapor density** ρ_v is the pounds of vapor in one cubic foot. **Mixture density** ρ_m is the sum of these, i.e., the pounds of air plus vapor in one cubic foot.

Table 4.1.2 Values of *n* (Water Vapor)

Initial quality	Initial pressure, psia											
	20	40	60	80	100	120	140	160	180	200	220	240
1.00	1.131	1.132	1.133	1.134	1.136	1.137	1.138	1.139	1.141	1.142	1.143	1.145
0.95	1.127	1.128	1.129	1.130	1.131	1.131	1.132	1.133	1.134	1.135	1.136	1.137
0.90	1.123	1.123	1.124	1.124	1.125	1.125	1.126	1.126	1.127	1.127	1.128	1.129
0.85	1.119	1.119	1.119	1.119	1.120	1.120	1.120	1.120	1.120	1.120	1.120	1.121
0.80	1.115	1.115	1.114	1.114	1.114	1.114	1.113	1.113	1.113	1.113	1.112	1.112
0.75	1.111	1.110	1.110	1.109	1.109	1.108	1.107	1.106	1.106	1.105	1.104	1.104

Notation The subscripts a, v, m, and f apply to air, vapor, mixture, and liquid water, respectively. The subscripts d and w apply to conditions pertaining to the dry- and wet-bulb temperature, respectively.

HUMIDITY MEASUREMENTS

Many methods are in use: (1) the **dew point** method measures the temperature at which condensation begins; water-vapor pressure can then be found from steam tables. Dew point apparatus can either cool a surface or compress and expand moist air. (2) **Hygrometers** measure relative humidity, often by using the change in dimensions of a hygroscopic material such as human hair, wood, or paper; these instruments are simple and inexpensive but require frequent calibration. The electrical resistance of an electrolytic film can also be used as an indication of relative humidity. (3) The wet- and dry-bulb **psychrometer** is widely used. Humidity measurements of air flowing in ducts can be made with psychrometers that use mercury-in-glass thermometers, thermocouples, or resistance thermometers. Humidity measurements of still air can be made with sling psychrometers as aspiration psychrometers. Psychrometric wet-bulb temperatures must be corrected to obtain thermodynamic wet-bulb temperatures, or there must be adequate air motion past the wet-bulb thermometer, 800 to 900 ft/min (with duct walls at air temperature), to ensure a proper balance between radiation and convection. (4) **Chemical analysis** by the use of desiccants such as sulfuric acid, phosphorus pentoxide, lithium chloride, or silica gel can be used as primary standards of humidity measurement.

The following equations give various properties in terms of pressure in inches Hg and temperature in degrees Fahrenheit.

Relative humidity: $r = p_v/p_d$
Specific humidity: $W = p_v/1.61(p_t - p_v)$ lb/lb dry air

Volume of mixture per pound of dry air:

$$v_a = \frac{1}{\rho_a} = 0.754(t_d + 460)/(p_t - rp_d) \quad \text{ft}^3$$

Volume of mixture per pound of mixture:

$$v_m = \frac{1}{\rho m} = v_a/(1 + W) \quad \text{ft}^3$$

The **enthalpy** of a mixture of dry air and steam, when each constituent is assumed to be an ideal gas, in Btu per pound of dry air, is the sum of the enthalpy of 1 lb of dry air and the enthalpy of the W lb of steam mixed with that air. The specific enthalpy of dry air (above 0°F) is $h_a = 0.240t_d$ (up to 130°F, the specific heat of dry air is 0.240; at higher temperatures, it is larger). The specific enthalpy of low-pressure steam (saturated or superheated) is nearly independent of the vapor pvessure and depends only on t_d. An empirical equation for the specific enthalpy of low-pressure steam for the range of temperatures from −40 to 250°F is

$$h_v = 1{,}062 + 0.44t_d \quad \text{Btu/lb}$$

The enthalpy of a mixture of air and steam is

$$h_m = 0.240t_d + W(1{,}062 + 0.44t_d)$$

The specific heat of a mixture of dry air and steam per pound of dry air may be called **humid specific heat** and is $0.240 + 0.44W$ Btu/lb dry air. For a steady-flow process without change of specific humidity, heat transfers per pound of dry air may be computed as the product of humid specific heat and change in dry-bulb temperature.

Thermodynamic Wet-Bulb Temperature (Temperature of Adiabatic Saturation) The thermodynamic wet-bulb temperature t^* is an important property of state of mixtures of dry air and superheated steam; it is the temperature at which water (or ice), by evaporating into a mixture of air and steam, will bring the mixture to saturation at the same temperature in a steady-flow process in the absence of external heat transfer. For a mixture of dry air and saturated steam only, $t^* = t_d$; where $r < 1$, $t^* < t_d$. By writing energy and mass balances for the process of adiabatic saturation with water supplied at t^*, the following equation may be derived:

$$W = W^* - \frac{(0.240 + 0.44W^*)(t_d - t^*)}{1{,}094 + 0.44t_d - t^*}$$

where W^* = specific humidity for saturation at the total pressure of p_t.

The enthalpy of a mixture of dry air and **saturated** steam at the total pressure p_t and thermodynamic wet-bulb temperature t^* exceeds the enthalpy of a mixture of dry air and **superheated** steam at the same p_t and t^* for

$$h_m^* = h_m + (W^* - W)h_f^*$$

A property of the mixture that remains constant for constant p_t and t^* has been called the Σ **function,** for

$$\Sigma^* = h_m^* - W^*h_f^* = \Sigma = h_m - Wh_f^*$$

EXAMPLE. A mixture of dry air and **saturated** steam; $p_t = 24$ inHg; $t_d = 76$°F. Partial pressure of water vapor from tables:

$$p_v = p_d = 0.905 \text{ inHg}$$

Partial pressure of dry air: $p_a = p_t - p_v = 23.095$ inHg.
Specific humidity:

$$W = 0.905/1.61(23.095) = 0.0243 \text{ lb/lb dry air}$$

Volume of mixture per pound of dry air:

$$v_a = 0.754(536)/23.095 = 17.5 \text{ ft}^3$$

Volume of mixture per pound of mixture:

$$v_m = 17.5/1.0243 = 17.1 \text{ ft}^3$$

Enthalpy of mixture:

$$h_m = 0.240(76) + 0.0243(1{,}095) = 44.85 \text{ Btu/lb dry air}$$

EXAMPLE. A mixture of dry air and **superheated** steam; $p_t = 24$ inHg; $t_d = 76$°F; $t_w = t^* = 62$°F.
Pressure of saturated steam at $t^* = 0.560$ inHg (from tables):

$$W^* = 0.560/1.61(23.44) = 0.01484 \text{ lb/lb dry air}$$

Specific humidity:

$$W = 0.01484 - \frac{0.2465(14)}{1{,}065.4} = 0.0116 \text{ lb/lb dry air}$$

Partial pressure of water vapor:

$$0.0116 = p_v/[1.61(24 - p_v)] \quad \text{and} \quad p_v = 0.44 \text{ inHg}$$

Relative humidity: $r = 0.44/0.905 = 0.486$.
Volume of mixture per pound of dry air:

$$v_a = 0.754(536)/23.56 = 17.2 \text{ ft}^3$$

Volume of mixture per pound of mixture:

$$v_m = 17.2/1.0116 = 17.0 \text{ ft}^3$$

Enthalpy of mixture:

$$h_m = 0.240(76) + 0.0116(1{,}095) = 30.95 \text{ Btu/lb dry air}$$

PSYCHROMETRIC CHARTS

For occasional use, algebraic equations are less confusing and more reliable; for frequent use, a **psychrometric chart** may be preferable. A disadvantage of charts is that each applies for only one value of barometric pressure, usually 760 mm or 30 inHg. Correction to other barometric readings is not simple. The equations have the advantage that the actual barometric pressure is taken into account. The equations are often more convenient for equal accuracy or more accurate for equal convenience.

Psychrometric charts are usually plotted, as indicated by Fig. 4.1.18, with dry-bulb temperature as abscissa and specific humidity as ordinate. Since the specific humidity is determined by the vapor pressure and the barometric pressure (which is constant for a given chart), and is nearly proportional to the vapor pressure, a second ordinate scale, departing slightly from uniform graduations, will give the vapor pressure. The

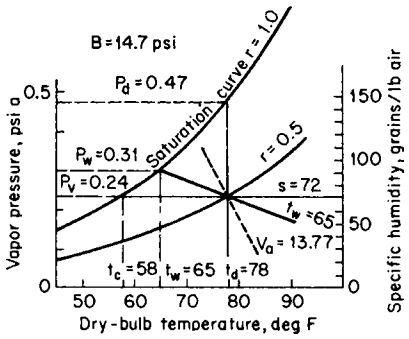

Fig. 4.1.18 Skeleton humidity chart.

saturation curve ($r = 1.0$) gives the specific humidity and vapor pressure for a mixture of air and saturated vapor. Similar curves below it give results for various values of relative humidity. Inclined lines of one set carry fixed values of the wet-bulb temperature, and those of another set carry fixed values of v_a, cubic feet per pound of air. Many charts carry additional scales of enthalpy or Σ function.

Any two values will locate the point representing the state of the atmosphere, and the desired values can be read directly.

Psychrometric charts at different temperatures and barometric pressures are useful in solving problems that fall outside the normal range indicated in Fig. 4.1.18. A collection ("trial set") of 17 different psychro-metric charts in both USCS and SI units, for low, normal, and high temperatures, at sea level and at four elevations above sea level, is available from the Carrier Corp., Syracuse, NY.

AIR CONDITIONING

Air-conditioning processes alter the temperature and specific humidity of the atmosphere. The weight of dry air remains constant and consequently computations are best based upon 1 lb of dry air.

Liquid water may enter or leave the apparatus. Its weight m_f lb of air is often merely the difference between the specific humidities of the entering and leaving atmospheres. Its specific enthalpy at the observed or assumed temperature of supply or removal t_f is

$$h_f = t_f - 32 \text{ Btu/lb of liquid}$$

Because most air conditioning involves steady-flow processes, thermal results are computed by the steady flow equation, written for 1 lb of air. Using subscript 1 for entering atmosphere and liquid water, and for heat supplied; and 2 for departing atmosphere and water, and for heat abstracted; the equation becomes (in the absence of work)

$$h_{m1} + m_{f1}h_{f1} + q_1 = h_{m2} + m_{f2}h_{f2} + q_2 \qquad \text{Btu/lb air}$$

Either or both values of m_f or q may be zero.

In terms of the sigma function, the steady-flow equation becomes

$$\Sigma_1 + W_1(t_{w1} + 32) + m_{f1}h_{f1} + q_1 = \Sigma_2 + W_2(t_{w2} - 32) + m_{f2}h_{f2} + q_2 \qquad \text{Btu/lb air}$$

Unit processes involved in air conditioning include heating and cooling an atmosphere above its dew point, cooling below the dew point, adiabatic saturation, and mixing of two atmospheres. These, in various sequences, make it possible to start with any given atmosphere and produce an atmosphere of any required characteristics.

Heating and cooling above the dew point entail no condensation of vapor. Barometric pressure and composition being unaltered, partial pressures remain constant. The process is represented in Fig. 4.1.19.

EXAMPLE. Initial conditions: $p_t = 28$ inHg; $t_a = 60°F$; $t_w = 50°F$; $p_v = 0.26$ inHg; $V = 1{,}200$ ft^3.

Final conditions: $t_d = 82°F$.

Initial computed values: $r = 0.50$; $W = 0.0058$ lb vapor/lb air; $\rho_a = 0.0707$ lb air/ft^3; $m_a = V \times \rho_a = 1{,}200 \times 0.0707 = 84.9$ lb air; $h_m = 20.7$ Btu/lb air.

Final computed values: p_v, W, and m_a unaltered; $r = 0.24$; $\rho_a = 0.0679$ lb air/ft^3; $V = m_a/p_a = 84.9/0.0679 = 1{,}250$ ft^3; $h_m = 26.1$ Btu/lb air.

Heat added: $q = h_{m2} - h_{m1} = 26.1 - 20.7 = 5.4$ Btu/lb air; $Q = q \times m_a = 5.4 \times 84.9 = 458$ Btu.

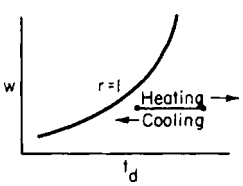

Fig. 4.1.19

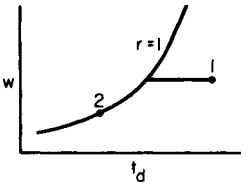

Fig. 4.1.20

Cooling below the dew point, and **dehumidification,** entails condensation of vapor; the final atmosphere will be saturated, liquid will appear (see Fig. 4.1.20).

EXAMPLE. Initial conditions: $p_t = 29$ inHg; $t_d = 75°F$; $t_w = 65°F$; $V = 1{,}500$ ft^3.

Final condition: $t_d = 45°F$.

Initial computed values: $W = 0.0113$ lb vapor/lb air; $\rho_a = 0.0706$ lb air/ft^3; $m_a = 1{,}500 \times 0.0706 = 106.0$ lb air; $h_m = 30.4$ Btu/lb air; $t_c = 60°F$.

Final computed values: $t_d = 45°F$; $p_v = 0.30$ inHg; $r = 1.0$; $W = 0.0065$ lb vapor/lb air; $\rho_a = 0.0754$ lb air/ft^3; $V = 106.0/0.0754 = 1{,}406$ ft^3; $h_m = 17.8$ Btu/lb air.

Liquid formed: $m_f = W_1 - W_2 = 0.0113 - 0.0065 = 0.0048$ lb liqud/lb air; $h_f = 50 - 32 = 18$ Btu/lb liquid (assuming that the liquid is drained out at an average temperature $t_f = 50°F$).

Heat abstracted: $q = h_{m1} - h_{m2} - m_f h_f = 30.4 - 17.8 - 0.0048 \times 18 = 12.5$ Btu/lb air; $Q = q \times m_a = 12.5 \times 106.0 = 1{,}325$ Btu.

Dehumidification may be accomplished in a **surface cooler,** in which the air passes over tubes cooled by brine or refrigerant flowing through them. The solution of this type of problem is most easily handled on the chart (see Fig. 4.1.21). Locate the point representing the state of the entering atmosphere, and draw a straight line to a point on the saturation curve ($r = 1.0$) at the temperature of the cooling surface. The final state of the issuing atmosphere is approximated by a point on this line whose position on the line is determined by the heat abstracted by the cooling medium. This depends upon the extent of surface and the coefficient of heat transfer.

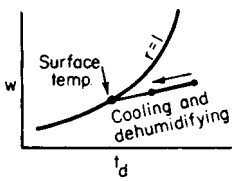

Fig. 4.1.21

Adiabatic saturation (humidification) may be conducted in a spray chamber through which atmosphere flows. A large excess of water is recirculated through spray nozzles, and evaporation is made up by a suitable water supply. After the process has been operating for some time, the water in the spray chamber will have been cooled to the temperature of adiabatic saturation, which differs from the wet-bulb temperature only because of radiation and velocity errors that affect the wet-bulb thermometer. No heat is added or abstracted; the process is adiabatic. The heat of vaporization for the water that is evaporated is supplied by the cooling of the air passing through the chamber. The wet-bulb temperature of the atmosphere is constant throughout the chamber (Fig. 4.1.22). If the chamber is sufficiently large, the issuing atmosphere will be saturated at the wet-bulb temperature of the entering atmosphere; i.e., as the atmosphere passes through the chamber, t_w remains constant, t_d is reduced from its initial value to t_w. In a chamber of commercial size, the action may terminate somewhat short of this,

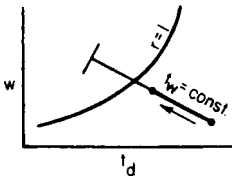

Fig. 4.1.22

the precise endpoint being determined by the duration and effectiveness of contact between air and spray water. In any case, the weight of water evaporated equals the increase in the specific humidity of the atmosphere.

EXAMPLE. Initial conditions $p_t = 30$ inHg; $t_d = 78°F$; $t_w = 55°F$; $r = 0.20$; $W = 28$ grains vapor/lb air.
Final conditions: $t_d = t_w = 55°F$; $r = 1.0$; $W = 64$ grains vapor/lb air.
Water evaporated: $W_2 - W_1 = 64 - 28 = 36$ grains water/lb air

The design of the spray chamber to produce this result is necessarily based upon experience with like apparatus previously built.

In practice, the spray chamber is preceded and followed by heating coils, the first to warm the entering atmosphere to the desired value of t_w, determined by the prescribed final specific humidity, the second to warm the issuing atmosphere to the desired temperature, and simultaneously to reduce its relative humidity to the desired value.

The **spray chamber** that is used for adiabatic saturation (humidification) in winter may be used for dehumidification in summer by supplying the spray nozzles with refrigerated water instead of recirculated water. In this case, the issuing atmosphere will be saturated at the temperature of the spray water, which will be held at the desired dew point. Subsequent heating of the atmosphere to an acceptable temperature will simultaneously reduce the relative humidity to the desired value.

Mixing Two Atmospheres In recirculating ventilation systems, two atmospheres (1 and 2) are mixed to form a third (3). The state of the final atmosphere is readily found graphically on the psychrometric chart (see Fig. 4.1.23). Locate the points 1 and 2 representing the states of the initial atmospheres. Connect these points by a straight line. Locate a point that divides this line into segments inversely proportional to the weights of air in the respective atmospheres. The division point represents the state of the final mixture, so long as it falls below the saturation curve ($r = 1$). If the final point falls above the saturation curve, as in Fig. 4.1.24, condensation will ensue, and the true final point 4 is found

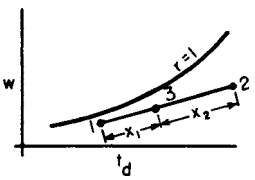

Fig. 4.1.23

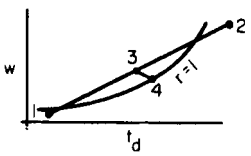

Fig. 4.1.24

by drawing a line from the apparent point 3, parallel to the lines of constant wet-bulb temperature, to its intersection with the saturation curve. From all the points involved, readings of specific humidity may be taken, including point 3 when it falls above the saturation curve, and in this case the difference between W_3 and W_4 will be the weight of condensate, pounds per pounds air.

If the chart is sectional and the two points do not fall in the same section, or in any case in which it is preferred, the same method may be carried out arithmetically.

For adiabatic mixing in a steady-flow process of two masses of "moist" air, each at the total pressure of p_t,

$$m_{a3} = m_{a1} + m_{a2}$$

In the absence of condensation,

and
$$m_{a3}W_3 = m_{a1}W_1 + m_{a2}W_2$$
$$m_{a3}h_{m3} = m_{a1}h_{m1} + m_{a2}h_{m2}$$

When condensation occurs, assume that the condensate is removed at the final temperature t_4 and that the final mixture consists of dry air and saturated water vapor at this same temperature. The weight of condensate is

$$m_c = m_{a1}W_1 + m_{a2}W_2 - m_{a3}W_4$$

where W_4 is the specific humidity for saturation at temperature t_4 and total pressure p_t. Also

$$m_{a1}h_{m1} + m_{a2}h_{m2} = m_{a2}h_{m4} + m_c h_{f4}$$

In the case of condensation, a trial solution is necessary to find the temperature t_4 that will satisfy these relations.

EXAMPLE. Two thousand ft³ of air per min at $t_{d1} = 80°F$ and $t_{w1} = 65°F$ are mixed in an adiabatic, steady-flow process with 1,000 ft³ of air per min at $t_{d2} = 95°F$ and $t_{w2} = 75°F$; the total pressure of each mixture is 29 inHg.
By computation, $m_{a1} = 140$ lb dry air/min; $W_1 = 0.010$ lb/lb dry air; $m_{a2} = 67.6$ lb dry air/min; $W_2 = 0.0146$ lb/lb dry air.
$m_{a3} = 207.6$ lb dry air/min.
$W_3 = 0.0116$ lb/lb dry air.
$h_{m1} = 30.3$ Btu/lb dry air and $h_{m2} = 38.9$ Btu/lb dry air.
$h_{m3} = 33.1$ Btu/lb dry air.
$t_{d3} = 84.9°F$.

EXAMPLE. Fifteen hundred ft³ of air per min at $t_{d1} = 0°F$ and $r_1 = 0.8$ are mixed in an adiabatic, steady-flow process with 1,000 ft³ of air per min at $t_{d2} = 100°F$ and $r_2 = 0.9$; the total pressure of each mixture is 30 inHg.
By computation, $m_{a1} = 129.6$ lb of dry air/min; $W_1 = 0.000626$ lb/lb dry air; $m_{a2} = 66.9$ lb of dry air/min; $W_2 = 0.03824$ lb/lb dry air; $h_{m1} = 0.09$ Btu/lb dry air; $h_{m2} = 66.29$ Btu/lb dry air.
The three equations that must be satisfied by a choice of the terminal temperature, $t_4 = t_{d4} = t_{w4}$, are

$$m_c = 2.64 - 196.5W_4$$
$$4551 = 196.5h_{m4} + m_c h_{f4}$$
$$W_4 = p_{v4}/1.61(30 - p_{v4}) \qquad \text{for } r_4 = 1$$

The value of t_4 that satisfies these equations is 55°F; condensation amounts to 0.84 lb/min.

The **cooling tower** is a chamber in which outdoor atmosphere flows through a spray of entering hot water, which is to be cooled. The temperature of the water is reduced in part by the warming of the air, and in greater part by the evaporation of a portion of the water. The atmosphere enters at given conditions and emerges at a higher temperature and usually saturated ($r = 1$). It is commonly possible to cool the water below the temperature of the entering air, often to about halfway between t_d and t_w. The volume of atmosphere per pound of entering water and the weight of water evaporated are to be computed.

EXAMPLE. A cooling tower is to receive water at 120°F and atmosphere at $t_d = 90$, $t_w = 80$, whence $p_v = 0.92$, $W = 0.0196$ lb vapor/lb air, $\rho_a = 0.0702$ lb air/ft³, and $h_m = 43.2$. The water is to be cooled to 85°F. What volume of atmosphere must be passed through the tower, and what weight of water will be lost by evaporation?
The issuing atmosphere will be assumed to be saturated at 115°F. Then $t_d = 115°F$, $p_v = 3.0$ inHg, $W = 0.0690$ lb vapor/lb air, $\rho_a = 0.0623$ lb air/ft³, and/$h_m = 104.4$ Btu/lb air.
The two unknowns are the weight of air to be passed through the tower and the weight of water to be evaporated. The two equations are the water-weight balance and the enthalpy balance (the steady-flow equation for zero heat transfer to or from outside). Assume that 1 lb water enters, of which x lb are evaporated. The water-weight balance $1 + m_a W_1 = 1 - x + m_a W_2$ becomes $x = m_a(W_2 - W_1) = m_a(0.0690 - 0.0196) = 0.0494m_a$. The enthalpy balance $1 \times (120 - 32) + m_a h_{m1} = (1 - x)(85 - 32) + m_a h_{m2}$ becomes $88 + 43.2m_a = 53(1 - x) + 104.4m_a$; whence $53x = 53 - 88 + m_a(104.4 - 43.2) = -35 + 61.2m_a$.
Solving these simultaneous equations, $x = 0.0295$ lb water evaporated per pound of water entering and $m_a = 0.597$ lb air per pound water entering.

In an **evaporative condenser,** vapor is condensed within tubes that are cooled by the evaporation of water flowing over the outside of the tubes; the water evaporates into the atmosphere. The computation of results is similar to that for the cooling tower.

REFRIGERATION

Vapor Compression Machines The essential parts of a vapor-compression system are the same as in the system using air, except that the expansion cylinder is replaced by an expansion value through which the liquefied medium flows from the high-pressure condensing coils to the low-pressure brine coils. The cycle of operation is best shown on the *T-S* plane (Fig. 4.1.25). The point *B* represents the state of the refrigerating medium leaving the brine coils and entering the compressor. Usually in this state the fluid is nearly dry saturated vapor; i.e., point *B* is near the saturation curve S_g. *BC* represents the assumed reversible adiabatic compression, during which the fluid is usually superheated. In the state *C*, the superheated vapor passes into the cooling coils and is cooled at constant pressure, as indicated by *CD*, and then condensed at temperature T_2, as shown by *DE*. The liquid now flows through the expansion valve into the brine coils. This is a throttling process, and the final-state point *A* is located on the T_1-line in such a position as to make the enthalpy for state *A* (= area $OHGAA_1$) equal to the enthalpy at *E* (= area $OHEE_1$). The mixture of liquid and vapor now absorbs heat from the brine and vaporizes, as indicated by *AB*.

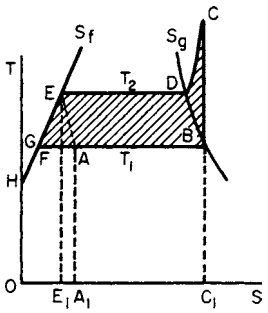

Fig. 4.1.25 Vapor compression refrigeration cycle.

The **heat absorbed from the brine,** represented by area A_1ABC_1, is

$$Q_1 = h_b - h_a = h_b - h_e$$

The **heat rejected to the cooling water,** represented by area C_1CDEE_1, is

$$Q_2 = h_c - h_e = c_p(T_c - T_d) + r_2 \qquad \text{approx}$$

where r_2 denotes the enthalpy of vaporization at the upper temperature T_2, and c_p the specific heat of the superheated vapor. The **work** that must be **supplied per pound of fluid circulated** is $W = Q_2 - Q_1 = h_c - h_b$. The ratio $Q_1/W = (h_b - h_e)/(h_c - h_b)$ is sometimes called the **coefficient of performance.**

If Q denotes the heat to be absorbed from the brine per hour, then the **quantity of fluid circulated per hour** is $m = Q/(h_b - h_a)$; or, if *B* is taken on the saturation curve, $m = Q/(h_{g1} - h_{f2})$.

The work per hour is $W = m(h_c - h_{g1}) = Q(h_c - h_{g1})/(h_{g1} - h_{f2})$ ft · lb, and the **horsepower required** is $H = Q(h_c - h_{g1})/2544(h_{g1} - h_{f2})$. The (U.S.) ton of refrigeration represents a cooling rate of 200 Btu/min, which is closely equivalent to that of 50 kcal/min, 210 kJ/min, or 3.5 kW. (Extensive tables of refrigerant properties are found in the "ASHRAE Handbook.")

If v_{g1} is the volume of the saturated vapor at the temperature T_1 in the brine coils, and n the number of working strokes per minute, the **displacement volume** of the **compressor cylinder** is $V = mv_{g1}/(60n)$.

The work necessary for operating a refrigerator, although usually supplied through the compressor, may be supplied in other ways. Thus in **absorption refrigerators** (see Secs. 12 and 19) an absorbent, usually water, absorbs the refrigerant, usually ammonia. The water, by its affinity for the ammonia, has, in a thermodynamic sense, ability to do work. Having absorbed the ammonia and thereby lost its ability to do work, the water may have its work capacity restored by passing the ammonia-water solution through a rectifying column from which water and ammonia emerge. With operation under a suitable pressure, the ammonia is condensed to a liquid. This, in turn, may be evaporated, yielding refrigeration, the ammonia vapors being once again absorbed in the water. Thermodynamically the analysis for these absorption cycles is similar to that for compression cycles. See Wood, "Applications of Thermodynamics," 2d ed., Addison-Wesley, for an in-depth discussion of the absorption refrigeration cycle.

Other papers on absorption refrigeration or **heat pump systems** include Chen, *Heat Recovery Systs. & CHP,* **30,** 1988, pp. 37–51; Narodoslawsky et al., *Heat Recovery Systs. & CHP,* **8,** no. 5, 1988, pp. 459–468, and **8,** no. 3, 1988, pp. 221–233; Egrican, **8,** no. 6, 1988, pp. 549–558; and for the aqua ammonia system, Ataer and Goguy, *Int. J. Refrig.,* **14,** Mar. 1991, pp. 86–92. Kalina (*J. Eng. Gas Turbines & Power,* **106,** 1984, pp. 737–742) proposed a new cycle using an ammonia-water solution as a bottoming cycle system. The proper selection of the composition and parameters of the working fluid was stated to be critical in the cycle design. Absorption replaces condensation of the working fluid after expansion in the turbine. Special care is also needed to regulate pressure drops between turbine stages. Chuang et al. [*AES (A.S.M.E.),* **10,** no. 3, 1989, pp. 73–77] evaluated exergy changes in the cycle while Kouremenos and Rogdaikis [*AES (A.S.M.E.),* **19,** 1990, pp. 13–19] developed a computer code for use with *h-s* and *T-s* diagrams. For heat pumps using **binary mixtures** see Hihara and Sato, *ASME/JSME Thermal Eng. Proc.,* **3,** 1991, p. 297. For **supercritical heat pump** cycles see, e.g., Angelino and Invernizzi, *Int. J. Refrig.,* **17,** no. 8, 1991; pp. 543–554.

An analysis of industrial gas separation to yield minimum overall cost, i.e., taking into account both energy and capital cost, for the processes of distillation, absorption, adsorption, and membranes was given by Haselden, *Gas Separation & Purification,* **3,** Dec. 1989, pp. 209–216. Analysis of the thermodynamic regenerator cycle with compressed-gas throttling, called the **Linde cycle,** was made by Lavrenchenko, *Cryogenics,* **33,** no. 11, 1993, pp. 1040–1045.

Orifice pulse tube refrigerators are receiving more attention. Kittel (*Cryogenics,* **32,** no. 9, 1992, pp. 843–844) examines their thermodynamic efficiency and refers to Radebaugh (*Adv. Cryog. Eng.,* **35B,** 1990, pp. 1192–1205) for a review of these devices.

de Rossi et al. (*Proc Mtg. IIR-IIF Comm.* B1, Tel Aviv, 1990) gave an interactive computer code for refrigerant thermodynamic properties which was evaluated for 20 different refrigerants in vapor compression and a reversed Rankine cycle (*Appl. Energy,* **38,** 1991, pp. 163–180). The evaluation included an exergy analysis. A similar publication was *AES (A.S.M.E.),* **3,** no. 2, 1987, pp. 23–31. Other papers include Kumar et al. (*Heat Recovery Systems & CHP,* **9,** no. 2, 1989, pp. 151–157), Alefeld (*Int. J. Refrig.,* **10,** Nov. 1987, pp. 331–341), and Nikolaidis and Probert (*Appl. Energy,* **43,** 1992, pp. 201–220).

The problem of deciding which refrigerants will be used in the future is complex. Although recommendations exist as to the phasing out of existing substances, one cannot predict the extent to which the recommendations will be followed. The blends proposed by seveial manufacturers have yet to receive extensive testing. One must bear in mind that in addition to the thermodynamic suitability considerations of material compatibility, ozone depletion potential, etc. have to be taken into account. According to Dr. McLinden of the National Institute of Standards and Technology, Boulder, CO (private communication, March 1995), R 11, R 12, R 22, R 123, R 134a as well as ammonia (R 717) and propane/isobutane (R 290/R 600a) blends are likely to be important for many years. The presentation of the tables in Sec. 4.2 has been revised to include some of these plus a few other compounds used in ternary blends. The best single source for further information is the "ASHRAE Handbook—Fundamentals," 1993 or latest edition.

STEAM CYCLES

Rankine Cycle The ideal Rankine cycle is generally employed by engineers as a standard of reference for comparing the performance of actual steam engines and steam turbines. Figure 4.1.26 shows this cycle on the *T-S* and *p-V* planes. *AB* represents the heating of the water in the boiler, BC represents evaporation (and superheating if there is any), *CD*

the assumed isentropic expansion in the engine cylinder, and *DA* condensation in the condenser.

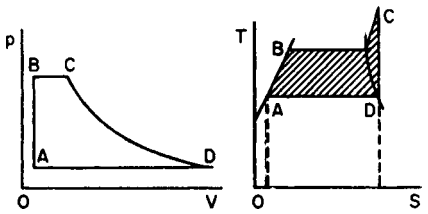

Fig. 4.1.26 Rankine cycle.

Let h_a, h_b, h_c, h_d represent the enthalpy per unit mass of steam in the four states *A*, *B*, *C*, and *D*, respectively. Then the energy transformed into work, represented by the area *ABCD,* is $h_c - h_d$ (enthalpies in Btu/lbm).

The energy expended on the fluid is $h_c - h_a$, hence the **Rankine cycle efficiency** is $e_t = (h_c - h_d)/(h_c - h_a)$.

The **steam consumption** of the ideal Rankine engine in pounds per horsepower-hour is $N_r = 2{,}544/(h_c - h_d)$. Expressed in pounds per kilowatthour, the steam consumption of the ideal Rankine cycle is $3{,}412.7/(h_c - h_d)$.

The performance of an engine is frequently stated in terms of the heat used per horsepower-hour. For the ideal Rankine engine, this is

$$Q_r = 2{,}544/e_t = 2{,}544(h_c - h_a)/(h_c - h_d)$$

Efficiency of the Actual Engine Let Q denote the heat transformed into work per pound of steam by the actual engine; then if Q_1 is the heat furnished by the boiler per pound of steam, the **thermal efficiency of the engine** is $e_t = Q/Q_1$.

The efficiency thus defined is misleading, as it takes no account of the conditions of boiler and condenser pressure, superheat, or quality of steam. It is customary therefore to define the efficiency as the ratio Q/Q_a, where Q_a is the **available heat,** or the heat that could be transformed under ideal conditions. For steam engines and turbines, the Rankine cycle is usually taken as the ideal, and the quantity $Q/Q_a = Q(h_c - h_d)$ is called the **engine efficiency.** For engines and turbines, this efficiency ranges from 0.50 to 0.85. The engine efficiency e may also be expressed in terms of steam consumed; thus, if N_a is the steam consumption of the actual engine and N_r is the steam consumption of the ideal Rankine engine under similar conditions, then $e = N_r/N_a$.

EXAMPLE. Suppose the boiler pressure to be 180 psia, superheat 150°F, and the condenser pressure 3 in of mercury. From the steam tables or diagiarn, the following values are found: $h_c = 1{,}283.3$, $h_d = 942$, $h_a = 82.99$. The available heat is $Q_a = 1{,}283.3 - 942 = 341.3$ Btu, and the thermodynamic efficiency of the cycle is $341.3/(1{,}283.3 - 82.99) = 0.284$. The steam consumption per horsepower-hour is $2{,}544/341.3 = 7.46$ lb, and the heat used per horsepower-hour is $2{,}544/0.284 = 8{,}960$ Btu. If an actual engine working under the same conditions has a steam consumption of 11.4 lb/(hp · h), its efficiency is $7.46/11.4 = 0.655$, and its heat consumption per horsepower-hour is $8{,}960/0.655 = 13{,}680$ Btu.

Reheating Cycle Let the steam after expansion from p_1 to an intermediate pressure p_2 (*cd*, Fig. 4.1.27) be reheated at constant pressure p_2, as indicated by *de*. Then follows the isentropic expansion to pressure p_3, represented by e_f.

The energy absorbed by 1 lb of steain is $h_c - h_a$ from the boiler, and $h_e - h_d$ from the reheating. The work done, neglecting the energy required to operate the boiler feed pump, etc., is $h_c - h_d + h_e - h_f$. Hence the efficiency of the cycle is

$$e_t = \frac{h_c - h_d + h_e - h_f}{h_c - h_a + h_e - h_d}$$

Bleeding Cycle In the **regenerative** or bleeding cycle, steam is drawn from the turbine at one or more stages and used to heat the feed water. Figure 4.1.28 shows a diagrammatic arrangement for bleeding at one stage. Entering the turbine is $1 + w$ lb of steam at p_1, t_1, and enthalpy h_1. At the bleeding point w lb at p_2, t_2, h_2 enters the feedwater heater. The remaining 1 lb passes through the turbine and condenser and enters the feedwater heater as water at temperature t_3. Let t' denote the temperature of the water leaving the heater, and h' the correspond-

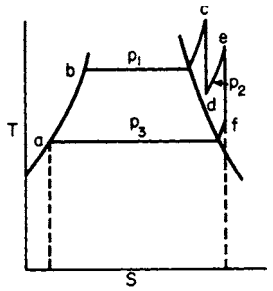

Fig. 4.1.27 Reheating cycle.

ing enthalpy of the liquid. Then the equation for the interchange of heat in the heater is

$$w(h_2 - h') = h' - h_{f3}$$

The work done by the bled steam is $w(h_1 - h_2)$ and that by the 1 lb of steam going completely through the turbine is $h_1 - h_3$. Total work = $w(h_1 - h_2) + (h_1 - h_3)$ if work to the pumps is neglected. The heat supplied between feedwater heater and turbine is $(1 + w)(h_1 - h')$. Hence the ideal efficiency of the cycle is

$$e_t = \frac{w(h_1 - h_2) + h_1 - h_3}{(1 + w)(h - h')}$$

A **computer program** which is claimed to model the thermodynamic performance of any steam power system has been described by Thelen and Somerton [*AES, (A.S.M.E.),* **33,** 1994, pp. 167–175], extending an earlier analysis.

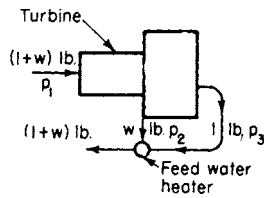

Fig. 4.1.28 Regenerative feedwater heating.

The use of selected fluid mixtures in Rankine cycles was proposed by Radermacher (*Int. J. Ht. Fluid Flow,* **10,** no. 2, June 1989, p. 90). Lee and Kim (*Energy Convsn. Mgmt.,* **33,** no. 1, 1992, pp. 59–67) describe the finite time optimization of a modified Rankine heat engine. For a steam Wankel engine see Badr et al. (*Appl. Energy,* **40,** 1991, pp. 157–190).

Heat from **nuclear reactors** can be used for heating services or, through thermodynamic cycles, for power purposes. The reactor coolant transfers the heat generated by fission so as to be used directly, or through an intermediate heat-exchange system, avoiding radioactive contamination. Steam is the preferred thermodynamic fluid in practice so that the Rankine-cycle performance standards with regenerative and reheat variations prevail. Adaptation of gas-turbine cycles, using various gases, can be expected as allowable reactor temperatures are raised.

Many engineers and scientists are actively engaged in research dealing with the location, production, utilization, transmission, storage, and distribution of new forms of energy. Examples are the study of the energy released in the fusion of hydrogen nuclei and research in solar energy. Considerable effort is being expended in studying the feasibility of combining the gas turbine with a steam-generating plant. The possibility

of efficiency improvement over the steam cycle is due to higher inlet temperatures associated with the gas turbine. Significant advances are predicted in the near future in expanding our energy sources and reserves.

THERMODYNAMICS OF FLOW OF COMPRESSIBLE FLUIDS

Important examples of the flow of compressible fluids are the following: (1) the flow of air and steam through orifices and short tubes or nozzles, as in the steam turbine, (2) the flow of compressed air, steam, and illuminating gas in long mains, (3) the flow of low-pressure gases, as furnace gases in ducts and chimneys or air in ventilating ducts, and (4) the flow of gases in moving channels, as in the centrifugal fan.

Notation

Let A = area of section, ft^2
C = empirically determined coefficient of discharge
D = inside diameter of pipe, ft
$d = 12D$ = inside diameter of pipe, in
F_{12} = energy expended in overcoming internal and external friction between sections A_1 and A_2
F' = energy used in overcoming friction, ft · lb/lb of fluid flowing
f = friction factor $= 4f'$
g = 32.2 = local acceleration of gravity, ft/s^2
g_c = a dimensional constant
h = enthalpy, Btu/lb
J = 778.3 ft · lb/Btu
$k = c_p/c_v$
L = equivalent length of pipe, ft
m = mass of fluid flowing past a given section per s, lb
μ = viscosity, cP
P = pressure, lb/in^2 abs
ΔP = differential pressure across nozzle, lb/in^2
p = pressure of fluid at given section, lb/ft^2 abs
p_m = critical flow pressure
Q_{12} = heat entering the flowing fluid between sections A_1 and A_2
q = volume of fluid flowing past section, ft^3/min
R = ideal gas constant
ρ = density, lb/ft^3
T = temperature, °R
$\bar{v}$ = mean velocity at the given section, ft/s
v = specific volume
w = weight of fluid power flowing past a given section per s, lb
z = height from center of gravity of flow to fixed base level, ft

The cross sections of the tube or channel are denoted by A_1, A_2, etc. (Fig. 4.1.29), and the various magnitudes pertaining to these sections are denoted by corresponding subscripts. Thus, at section A_1, the velocity, specific volume, and pressure are, respectively, $\bar{v}_1$, v_1, p_1; at section A_2, they are $\bar{v}_2$, v_2, p_2.

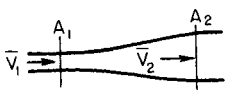

Fig. 4.1.29

Fundamental Equations In the interpretation of fluid-flow phenomena, three fundamental equations are of importance.

1. The continuity equation, or material balance,

$$\frac{A_1\bar{v}_1}{v_1} = \frac{A_2\bar{v}_2}{v_2} \quad \text{or} \quad \frac{dv}{v} = \frac{dA}{A} + \frac{d\bar{v}}{\bar{v}}$$

2. The first law of energy balance for steady flow,

$$q = (h_2 - h_1) + \frac{\bar{v}_2^2 - \bar{v}_1^2}{2g_c} + \frac{g}{g_c}(z_2 - z_1)$$

3. The available energy balance for a steady-flow process, based on unit weight, is

$$v\,dp + \frac{\bar{v}\,d\bar{v}}{g} + dF + dz = 0$$

In the process here discussed, no net external or shaft work is performed.

For most actual processes, the third equation cannot be integrated because the actual path is not known. Usually, adiabatic flow is assumed, but occasionally the assumption of isothermal conditions may be more nearly correct.

For **adiabatic flow of imcompressible fluids,** the last equation above can be written in the more familiar form known as Bernoulli's equation:

$$(p_2 - p_1)/\rho + (\bar{v}_2^2 - \bar{v}_1^2)/2 + g/g_c(z_2 - z_1) = 0$$

Flow through Orifices and Nozzles As a compressible fluid passes through a nozzle, drop in pressure and simultaneous increase in velocity result. By assuming the type of flow, e.g., adiabatic, it is possible to calculate from the properties of the fluid the required area for the cross section of the nozzle at any point in order that the flowing fluid may just fill the provided space. From this calculation, it is found that for all compressible fluids the nozzle form must first be converging but eventually, if the pressure drops sufficiently, a place is reached where to accommodate the increased volume due to the expansion the nozzle must become diverging in form. The smallest cross section of the nozzle is called the throat, and the pressure at the throat is the **critical flow pressure** (not to be confused with the critical pressure). If the nozzle is cut off at the throat with no diverging section and the pressure at the discharge end is progressively decreased, with fixed inlet pressure, the amount of fluid passing increases until the discharge pressure equals the critical, but further decrease in discharge pressure does not result in increased flow. This is not true for thin plate orifices. For any particular gas, the ratio of critical to inlet pressure is approximately constant. For gases, $p_m/p_1 = 0.53$ approx; for saturated steam the ratio is about 0.575; and for moderately superheated steam it is about 0.55.

Formulas for Orifice Computations The general fundamental relation is given by the energy balance $(\bar{v}_2^2 - \bar{v}_1^2)/(2g_c) = -h_{12}$. Referring to Fig. 4.1.30, let section 2 be taken at the orifice, section 3 is somewhat

Fig. 4.1.30

beyond the orifice on the downstream side, and section 1 is before the orifice on the upstream side. Then

$$\bar{v}_2 = C\sqrt{2g_c(h_1 - h_2)} \Big/ \sqrt{1 - \left(\frac{A_2}{A_1}\right)^2\left(\frac{v_1}{v_2}\right)^2}$$

The coefficient of discharge C is discussed in Secs. 3 and 16. The volume of gas passing is $\bar{v}_2A_2$ ft^3/s, and the quantity is $\bar{v}_2A_2p$. For ideal gases, assuming reversible adiabatic expansion through the orifice,

$$\bar{v}_2 = C\frac{\sqrt{2g_cp_1\bar{v}_1\dfrac{k}{k-1}\left[1 - \left(\dfrac{p_2}{p_1}\right)^{(k-1)/k}\right]}}{\sqrt{1 - \left(\dfrac{A_2}{A_1}\right)^2\left(\dfrac{p_2}{p_1}\right)^{2/k}}}$$

$$m = CA_2p_2\frac{\sqrt{\dfrac{2g_c}{RT_1}\dfrac{k}{k-1}\left(\dfrac{p_1}{p_2}\right)^{(k-1)/k}\left[\left(\dfrac{p_1}{p_2}\right)^{(k-1)/k} - 1\right]}}{\sqrt{1 - \left(\dfrac{A_2}{A_1}\right)^2\left(\dfrac{p_2}{p_1}\right)^{2/k}}}$$

Often $\bar{v}_1$ is small compared with $\bar{v}_2$, and under these conditions the denominators in the preceding equations become approximately equal

Table 4.1.3 Values for Y'

	$k = 1.40$					$k = 1.35$					$k = 1.30$

If the velocity of approach is zero (as with a nozzle taking in air from the outside), d_1 is infinite and d_n/d_1 is zero.

to unity. For air, assuming $R = 53.3$, $k = 1.3937$, and $\bar{v}_1$ negligible,

$$m = 2.05CA_2p_2\sqrt{(1/T_1)(p_1/p_2)^{0.283}[(p_1/p_2)^{0.283} - 1]}$$

Although the preceding formulas are generally applicable under the assumed conditions, it must be remembered that irrespective of the value of p_3, p_2 cannot become less than p_m. When p_3 is less than p_m, the flow rate becomes independent of the downstream pressure; for ideal gases,

$$m = CA_2p_1\sqrt{\frac{g_c}{RT_1}k\left(\frac{2}{k+1}\right)^{(k+1)(k-1)}}$$

or for air

$$m = 0.53Cp_1\frac{A_2}{\sqrt{T_1}}$$

The following formula is useful for calculating the flow rate, in cubic feet per minute, of any gas (provided no condensation occurs) through a nozzle for pressure drops less than the critical range:

$$q_1 = \frac{31.5Cd_n^2Y'}{\rho_1}\sqrt{\rho_1\Delta P}$$

In this equation,

$$Y' = \left(\frac{k}{k-1}\right)^{1/2}\left(\frac{P_2}{P_1}\right)^{1/k} \times \sqrt{\left[1 - \left(\frac{P_2}{P_1}\right)^{(k-1)/k}\right] \Big/ \left(1 - \frac{P_2}{P_1}\right)\left[1 - \left(\frac{d_n}{d_1}\right)^4\left(\frac{P_2}{P_1}\right)^{2/k}\right]}$$

where P_1 = static pressure on upstream side of nozzle, psia; P_2 = static pressure on downstream side of nozzle, psia; d_1 = diameter of pipe upstream of nozzle, in; d_n = nozzle throat diameter, in; ρ_1 = specific weight of gas at upstream side of nozzle, lb/ft^3. Values of Y' are given in Table 4.1.3.

Where the pressure drop through the orifice is small, the hydraulic formulas applicable to incompressible fluids may be employed for gases and other compressible fluids.

In general, the formulas of the preceding section are applicable to nozzles. When so used, however, the proper value of the discharge coefficient must be employed. For steam nozzles, this may be as high as 0.94 to 0.96, although for many orifice installations it is as low as 0.50 to 0.60. Steam nozzles constitute a most important type, and calculations for these are best carried out with the aid of a Mollier or similar chart.

Formulas for Discharge of Steam When the back pressure p_3 is less than the critical pressure p_m, the discharge depends upon the area of orifice A_2 and reservoir pressure p_1. There are three formulas widely used to express, approximately, the discharge m of **saturated** steam in terms of A_2 and p_1 as follows:

1. Napier's equation, $m = A_2p_1/70$.
2. Grashof's formula, $m = 0.0165A_2p_1^{0.97}$.
3. Rateau's formula, $m = A_2p_1(16.367 - 0.96 \log p_1)/1{,}000$.

In these formulas, A_2 is to be taken in square inches, p_1 in pounds per square inch. Napier's formula is merely convenient as a rough check. Formulas 2 and 3 are applicable to well-rounded convergent orifices, in which case the coefficient of discharge may be taken as 1; i.e., no correction is required.

When the back pressure p_2 is greater than the critical flow pressure p_m, the velocity and discharge are found most conveniently from the general formulas of flow. From the steam tables or from the **Mollier chart,** find the initial enthalpy h_1 and the enthalpy h_2 after isentropic expansion; also the specific volume v_2 (see Fig. 4.1.31). Then

$$\bar{v}_2 = 223.7\sqrt{h_1 - h_2} \qquad \text{and} \qquad m = A_2\bar{v}_2/v_2$$

The same method is used in the case of steam initially superheated.

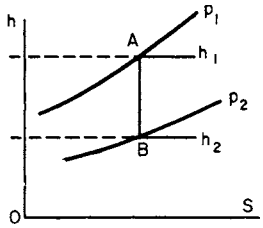

Fig. 4.1.31

EXAMPLE. Required the discharge through an orifice ½ in diam of steam at 140 psi superheated 110°F, back pressure, 90 psia.

From the Mollier chart and the steam tables, $h_1 = 1{,}255.7$, $h_2 = 1{,}214$, $v_2 = 5.30$ ft^3.

$$\bar{v}_2 = 233.7\sqrt{1{,}255.7 - 1{,}214} = 1{,}455$$
$$A_2 = 0.1964 \text{ in}^2 = (0.1964/144) \text{ ft}^2$$
$$m = A_2\bar{v}_2/v_2 = (0.1964/144) \times (1{,}455/5.30) = 0.372 \text{ lb/s}$$

This calculation assumes ideal conditions, and the results must be multiplied by the correct coefficient of discharge to get actual results.

Flow through Converging-Diverging Nozzles At the throat, or smallest cross section of the nozzle (Fig. 4.1.32), the pressure of saturated steam takes the value $p_m = 0.57p_1$. The quantity discharged is fixed by the area A_2 of the throat and the initial pressure p_1. For saturated steam, Grashof's or Rateau's formula (see above) may be used. The diverging part of the nozzle permits further expansion to the break pressure p_3, the velocity of the jet meanwhile increasing from $\bar{v}_m(=\bar{v}_2)$, the critical velocity at the throat, to $\bar{v}_3$ given by the fundamental equation $\bar{v}_3 = 223.7\sqrt{h_1 - h_3}$.

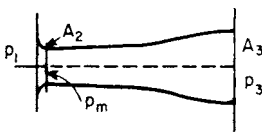

Fig. 4.1.32

The frictional resistances in the nozzle have the effect of decreasing the jet energy $\bar{v}_3^2/(2g_c)$ and correspondingly increasing the enthalpy of the flowing fluid. Thus, if h_3 is the enthalpy in the final state with frictionless expansion, h_3' $(>h_3)$ is the enthalpy when friction is taken into account; hence $(\bar{v}_3')^2/(2g_c) = (h_1 - h_3')$ is less than $\bar{v}_3^2/g_c = h_1 - h_3$. The loss of kinetic energy, in Btu, is $h_3' - h_3$, and the ratio of this loss to the available kinetic energy, i.e., $(h_3' - h_3)/(h_1 - h_3)$, is denoted by y.

The **design of a nozzle for a given discharge** m with pressures p_1 and p_3 is most conveniently effected with the aid of the Mollier chart. Determine p_m, the critical pressure, and h_1, h_m, h_3, assuming frictionless flow. Then

$$\bar{v}_m = 223.7\sqrt{h_1 - h_m}$$

and

$$\bar{v}_3' = 223.7\sqrt{(1 - y)(h_1 - h_3)}$$

Next find v_m and v_3'. Then, from the equation of continuity,

$$A_m = mv_m/\bar{v}_m$$

and

$$A_3' = mv_3'/\bar{v}_3'$$

The following example illustrates the method.

EXAMPLE. Required the throat and end sections of a nozzle to deliver 0.7 lb of steam per second. The initial pressure is 160 psia, the back pressure 15 psia, and the steam is initially superheated 100°F; $y = 0.15$.

The critical pressure is $160 \times 0.55 = 88$ lb. On the Mollier chart (Fig. 4.1.33), the point A representing the initial state is located, and line of constant entropy (frictionless adiabatic) is drawn from A. This cuts the curves $p = 88$ and $p = 15$ in the points B and C, respectively. The three values of h are found to be $h_1 = 1{,}253$, $h_m = 1{,}199$, $h_3 = 1{,}067$. Of the available drop in enthalpy, $h_1 - h_3 = 185.5$ Btu,

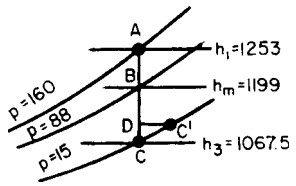

Fig. 4.1.33

15 percent or 27.9 Btu is lost through friction. Hence, $CD = 27.9$ is laid off and D is projected horizontally to point C' on the curve $p = 15$. Then C' represents the final state of the steam, and the quality is found to be $x = 0.943$. The specific volume in the state C' is $26.29 \times 0.943 = 24.8$ ft^3. Likewise, the specific volume for the state B is found to be 5.29 ft^3/lb.

For the velocities at throat and end sections,

$$\bar{v}_m = 223.7\sqrt{1{,}253 - 1{,}199} = 1{,}643 \text{ ft/s}$$
$$\bar{v}_3 = 223.7\sqrt{185.5 - 27.9} = 2{,}813 \text{ ft/s}$$
$$A_m = (0.7 \times 5.29)/1{,}643 = 0.00225 \text{ ft}^2 = 0.324 \text{ in}^2$$
$$A_3 = (0.7 \times 24.8)/2{,}813 = 0.00617 \text{ ft}^2 = 0.89 \text{ in}^2$$

The diameters are $d_m = 0.643$ in and $d_3 = 1.064$ in.

Divergence of Nozzles Figure 4.1.34 gives, for various ratios of expansion, the required "divergence" of nozzle, i.e., the ratio of the area of any section to the throat area. Thus in the case of saturated steam, if the final pressure is 1/15 of the initial pressure the ratio of the areas is 3.25. The curves apply to frictionless flow; the effect of friction is to increase the divergence.

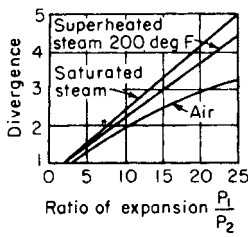

Fig. 4.1.34

Theory of Supersaturation Certain discrepancies between the discharge of saturated steam through an orifice as calculated from the preceding theory and the discharge actually observed are explained by a hypothesis first advanced by Martin, viz., that steam when expanded rapidly, as in turbine nozzles, becomes supersaturated; in other words, the condensation required by the ordinary theory of adiabatic expansion does not occur on account of the rapidity of the expansion.

The effect of supersaturation in turbines is a loss of energy, the amount of which may be 1.5 to 3 percent of the available energy of the steam.

Flow of Wet Steam When the steam entering a nozzle is wet, the speed of the water particles at exit is not the same as the speed of the steam. Denoting by $\bar{v}$ the speed of the steam, the speed of the water drop is $f\bar{v}$, and f may vary perhaps 0.20 to 0.05 or less, depending on the pressure. The actual velocity $\bar{v}$ of the steam is greater than the velocity $\bar{v}_0$ calculated on the usual assumption that steam and water have the same velocity. If x is the quality of the steam, the ratio of these velocities is

$$\bar{v}/\bar{v}_0 = 1/\sqrt{x + f^2(1 - x)}$$

Thus with $x = 0.92$, $f = 0.15$, $\bar{v}/\bar{v}_0 = 1.036$. Since the discharge is practically proportional to the steam velocity, the actual discharge in this case is 3.6 percent greater than the discharge computed on the usual assumptions.

Velocity Coefficients, Loss of Energy *y* On account of friction losses, the actual velocity $\bar{v}$ attained by the jet is less than the velocity $\bar{v}_0$ calculated under ideal conditions. That is, $\bar{v} = x\bar{v}_0$, where x (<1) is a velocity coefficient. The coefficient x is connected with the coefficient y, giving the loss of energy, by the relation, $y = 1 - x^2$.

The elaborate and accurate experiments of the General Electric Co. on turbine nozzles give convergent nozzles values of x in excess of 0.98, with a corresponding loss of energy $y = 0.025$ to 0.04. For similar nozzles, the experiments of the Steam Nozzles Research Committee (of England) by a different method give values of x around 0.96, or $y = 0.08$. In the case of divergent nozzles, the velocity coefficient may be somewhat lower.

FLOW OF FLUIDS IN CIRCULAR PIPES

The fundamental equation as previously given on a unit weight bases, assuming the pipe horizontal, is

$$(\bar{v}\, d\bar{v}/g) + v\, dp + dF = 0$$

The friction term dF includes not only losses due to frictional flow along the pipe but also those due to fittings, valves, etc., as well as losses occasioned by any enlargement or contraction of the pipe as, for instance, the loss occurring when a fluid passes from a pipe into a tank. For long straight pipes of uniform diameter, dF is approximately equal to $2f'[\bar{v}^2 dL/(gD)]$. It is usual to express friction due to fittings, etc., in terms of additional length of pipe, adding this to the actual pipe length to get the equivalent pipe length.

Integration of the fundamental equation leads to two sets of formulas.

1. For pressure drops, small relative to the initial pressure, the specific volume v and the velocity $\bar{v}$ may be assumed constant. Then approximately

$$p_1 - p_2 = 2f'\bar{v}^2 L/(vgD)$$

Expressing pressure in pounds per square inch, p', the diameter in inches, and $\bar{v}$ as a function of wv/d^2, this equation becomes

$$p'_1 - p'_2 = 174.2f'w^2vL/d^5$$

2. For considerable pressure drops, when dealing with approximately isothermal flow of gases and vapors to which the gas laws are applicable, the fundamental equation on a weight basis may be integrated to give

$$p_1^2 - p_2^2 = \frac{2w^2RT}{gA^2}\ln\frac{v_2}{v_1} + \frac{4f'RTw^2L}{gA^2D}$$

Coefficients of Friction The coefficient of friction f is not a constant but is a function of the dimensionless expression $\mu/(\rho\bar{v}a)$ or $\mu v/(\bar{v}d)$, which is the reciprocal of the Reynolds number. McAdams and Sherwood formulate the expression

$$f' = 0.0054 + 0.375[\mu v/(\bar{v}d)]$$

This formula is applicable to water and other fluids. For high-pressure steam, the second term in the expression is small and f' is approximately equal to 0.0054. Babcock has suggested the approximation $f' = 0.0027(1 + 3.6/d)$ for steam.

Values of $f = 4f'$ as a function of pipe surface are given in Sec. 3.3.

For predicting the capacity of a given pipe operating on a chosen fluid with fixed pressure drop, the use of Fig. 4.1.35 eliminates the trial-and-error methods usually involved.

Resistances due to fittings, expressed in terms of L/D, are as follows: 90° elbows, 1–2½ (3–6) [7–10] in, 30 (40) [50]; 90° curves, radius of centerline of curve 2–8 pipe diameters, 10; globe valves, 1–2½ (3–6) [7–10] in, 45 (60) [75]; tees, 1−4 in, 60. The resistance in energy units, due to sudden enlargement in a pipe, is approximately $(\bar{v}_1 - \bar{v}_2)^2/(2g)$, For sudden contraction it is $1.5(1 - r)\bar{v}_2^2/[2g(3 - r)]$, where $r = A_2/A_1$. Arnold, London, with a review of basic equations and tabular data for the isentropic flow of dry air with Prandtl-Meyer expansion angles, Rayleigh flow, Fanno flow, and plane normal and oblique shock wave tables; Shapiro, "The Dynamics and Thermodynamics of Compressible Fluid Flow," Ronald Press, New York; Blevins, "Applied Fluid Dynamics Handbook," Van Nostrand Reinhold.)

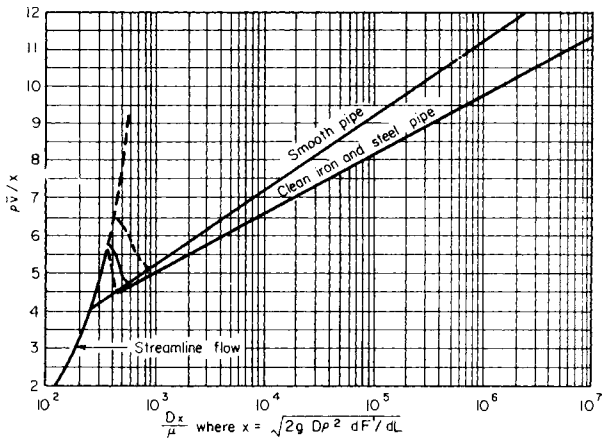

Fig. 4.1.35 Chart for estimating rate of flow from the pressure gradient.

THROTTLING

Throttling or Wire Drawing When a fluid flows from a region of higher pressure into a region of lower pressure through a valve or constricted passage, it is said to be throttled or wire-drawn. Examples are seen in the passage of steam through pressure-reducing valves, in the flow through ports and passages in the steam engine, and in the expansion valve of the refrigerating machine.

The **general equation applicable to throttling processes** is

$$(\bar{v}_2^2 - \bar{v}_1^2)/(2g_c) = h_1 - h_2$$

The velocities $\bar{v}_2$ and $\bar{v}_1$ are practically equal, and it follows that $h_1 = h_2$; i.e., in a throttling process there is no change in enthalpy.

For a mixture of liquid and vapor, $h = h_f + xh_{fg}$; hence the equation of throttling is $h_{f1} + x_1h_{fg1} = h_{f2} + x_2h_{fg2}$. In the case of a perfect gas, $h = c_pT + h_0$; hence the equation of throttling is $c_pT_1 + h_0 = c_pT_2 + h_0$, or $T_1 = T_2$.

Joule-Thomson Effect The investigations of Joule and Lord Kelvin showed that a gas drops in temperature when throttled. This is not universally true. For some gases, notably hydrogen, the temperature rises for throttling processes over ordinary ranges of temperature and pressure. Whether there is a rise or fall in temperature depends on the particular range of pressure and temperature over which the change occurs. For each gas, there are different values of pressure and temperature at which no temperature change occurs during a Joule-Thomson expansion. That temperature is called the inversion temperature. Below this temperature, a gas cools on throttling; above it, its temperature rises. The ratio of the observed drop in temperature to the drop in pressure, i.e., dT/dP, is the Joule-Thomson coefficient. In actual design, the effect of heat leaks must be carefully evaluated before the theoretical Joule-Thomson coefficients are applied.

Figure 4.1.36 shows the variation of inversion temperature with pressure and temperature; the exact values are shown in Table 4.1.4. The inversion locus for air is shown in Table 4.1.5.

The cooling **effect produced by throttling** has been applied to the liquefaction of gases.

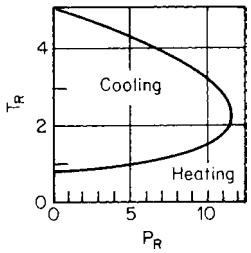

Fig. 4.1.36 Inversion curve.

Loss due to Throttling A throttling process in a cycle of operations always introduces a loss of efficiency. If T_0 is the temperature corresponding to the back pressure, the loss of available energy is the product of T_0 and the increase of entropy during the throttling process. The following example illustrates the calculation in the case of ammonia passing through the expansion valve of a refrigerating machine.

EXAMPLE. The liquid ammonia at a temperature of 70°F passes through the valve into the brine coil in which the temperature is 20 deg and the pressure is 48.21 psia. The initial enthalpy of the liquid ammonia is $h_{f1} = 120.5$, and therefore the final enthalpy is $h_{f2} + x_2 h_{fg2} = 64.7 + 553.1x_2 = 120.5$, whence $x_2 = 0.101$. The initial entropy is $s_{f1} = 0.254$. The final entropy is $s_{f2} + (x_2 h_{fg2}/T_2) = 0.144 + 0.101 \times 1.153 = 0.260$. $T_0 = 20 + 460 = 480$; hence the loss of refrigerating effect is $480 \times (0.260 - 0.254) = 2.9$ Btu.

Fuels For special properties of various fuels, see Sec. 7. In general, fuels may be classed under three headings: (1) gaseous fuels, (2) liquid fuels, and (3) solid fuels.

The combustible elements that characterize fuels are carbon, hydrogen, and, in some cases, sulfur. The complete combustion of carbon gives, as a product, carbon dioxide, CO_2; the combustion of hydrogen gives water, H_2O.

Combustion of Gaseous and Liquid Fuels

Combustion Equations The approximate molecular weights of the important elements and compounds entering into combustion calculations are:

Material	C	H_2	O_2	N_2	CO	CO_2	H_2O
Molecular weight	12	2	32	28	28	44	18
Material	CH_4	C_2H_4	C_2H_6O	S	NO	NO_2	SO_2
Molecular weight	16	28	46	32	30	46	64

For the elements C and H, the equations of complete combustion are

$$C + O_2 = CO_2 \qquad H_2 + \tfrac{1}{2}O_2 = H_2O$$
$$12 \text{ lb} + 32 \text{ lb} = 44 \text{ lb} \qquad 2 \text{ lb} + 16 \text{ lb} = 18 \text{ lb}$$

For a combustible compound, as CH_4, the equation may be written

$$CH_4 + x \cdot O_2 = y \cdot CO_2 + z \cdot H_2O$$

Taking, as a basis, 1 molecule of CH_4 and making a balance of the atoms on the two sides of the equation, it is seen that

$$y = 1 \qquad z = 2 \qquad 2x = 2y + z \qquad \text{or} \qquad x = 2$$

Hence,

$$CH_4 + 2O_2 = CO_2 + 2H_2O$$
$$16 \text{ lb} + 64 \text{ lb} = 44 \text{ lb} + 36 \text{ lb}$$

The coefficients in the combustion equation give the combining volumes of the gaseous components. Thus, in the last equation 1 ft^3 of CH_4 requires for combustion 2 ft^3 of oxygen and the resulting gaseous products of combustion are 1 ft^3 of CO_2 and 2 ft^3 of H_2O. The coefficients multiplied by the corresponding molecular weights give the combining weights. These are conveniently referred to 1 lb of the fuel. In the combustion of CH_4, for example, 1 lb of CH_4 requires $64/16 = 4$ lb of oxygen for complete combustion and the products are $44/16 = 2.75$ lb of CO_2 and $36/16 = 2.25$ lb of H_2O.

Air Required for Combustion The composition of air is approximately 0.232 O_2 and 0.768 N_2 on a pound basis, or 0.21 O_2 and 0.79 N_2 by volume. For exact analyses, it may be necessary sometimes to take account of the water vapor mixed with the air, but ordinarily this may be neglected.

The minimum amount of air required for the combustion of 1 lb of a fuel is the quantity of oxygen required, as found from the combustion equation, divided by 0.232. Likewise, the minimum volume of air required for the combustion of 1 ft^3 of a fuel gas is the volume of oxygen divided by 0.21. For example, in the combustion of CH_4 the air required per pound of CH_4 is $4/0.232 = 17.24$ lb and the volume of air per cubic foot of CH_4 is $2/0.21 = 9.52$ ft^3. Ordinarily, more air is provided than is required for complete combustion. Let a denote the minimum amount required and xa the quantity of air admitted; then $x - 1$ is the **excess coefficent.**

Products of Combustion The products arising from the complete combustion of a fuel are CO_2, H_2O, and if sulfur is present, SO_2. Accompanying these are the nitrogen brought in with the air and the oxygen in the excess of air. Hence the products of complete combustion are principally CO_2, H_2O, N_2, and O_2. The **presence of CO indicates incomplete combustion.** In simple calculations the reaction of nitrogen with oxygen to form noxious oxides, often termed NO_x, such as nitric oxide (NO), nitrogen peroxide (NO_2), etc., is neglected. In practice, an automobile engine is run at a lower compression ratio to reduce NO, formation. The reduced pollution is bought at the expense of reduced operating efficiency. The composition of the products of combustion is readily calculated from the combustion equations, as shown by the following illustrative example. (See also Table 4.1.7.)

EXAMPLE. A producer gas having the volume composition given is burned with 20 percent excess of air; required the volume composition of the exhaust gases.

	V
H_2	0.08
CO	0.22
CH_4	0.024
CO_2	0.066
N_2	0.61
	1.0

Coefficients in reaction equations			Coefficients multiplied by V		
O_2	CO_2	H_2O	O_2	CO_2	H_2O
0.5	0	1	0.04	0	0.08
0.5	1	0	0.11	0.22	0
2	1	2	0.048	0.024	0.048
0	1	0	0	0.066	0
0	0	0	0	0	0
			0.198	0.31	0.128

For 1 ft^3 of the producer gas, 0.198 ft^3 of O_2 is required for complete combustion. The minimum volume of air required is 0.198/0.21 = 0.943 ft^3 and with 20 percent excess the air supplied is 0.943 × 1.2 = 1.132 ft^3. Of this, 0.238 ft^3 is oxygen and 0.894 ft^3 is N_2. Consequently, for 1 ft^3 of the fuel gas, the exhaust gas contains

CO_2	0.31 ft^3
H_2O	0.128 ft^3
N_2	0.61 + 0.894 = 1.504 ft^3
O_2 (excess)	0.238 − 0.198 = 0.040 ft^3
	1.982 ft^2

or

CO_2	15.7 percent
H_2O	6.5 percent
N_2	75.8 percent
O_2	2.0 percent
	100.0 percent

Volume Contraction As a result of chemical action, there is often a change of volume; for example, in the reaction $2H_2 + O_2 = 2H_2O$, three volumes (two of H_2 and one of O_2) contract to two volumes of water vapor. In the example just given, the volume of producer gas and air supplied is 1 ft^3 gas + 1.132 ft^3 air = 2.132 ft^3, and the corresponding volume of the exhaust gas is 1.982 ft^3, showing a contraction of about 7 percent. For a hydrocarbon having the composition C_mH_n, the relative volume contraction is $1 - n/4$; thus for CH_4 and C_2H_4 there is no change of volume, for C_2H_2 the contraction is half the volume, and for C_2H_6 there is an increase of one-half in volume.

The change of volume accompanying a chemical reaction, such as a combustion, causes a corresponding change in the gas constant R. Let R' denote the constant for the mixture of gas and air (1 lb of gas and xa lb of air) before combustion, and R'' the constant of the mixture of resulting products of combustion. Then, if y is the resulting contraction of volume, $R''/R' = (1 + xa - y)/(1 + xa)$.

Heat of Combustion Usually, a chemical change is accompanied by the generation or absorption of heat. The union of a combustible with oxygen produces heat, and the heat thus generated when 1 lb of combustible is completely burned is called the **heat of combustion** or the **heat value** of the combustible. Heat values are determined experimentally by calorimeters in which the products of combustion are cooled to the initial temperature and the heat absorbed by the cooling medium is measured. This is called the **high heat value.**

The heat transferred (heat of combustion) during a combustion reaction is computed on either a constant-pressure or a constant-volume basis. The first law is used in the the analysis of either process.

1. The **heat value at constant volume** (Q_v). Consider a constant-volume combustion process where several reactants combine under proper conditions to form one or more products. The heat of combustion under constant-volume conditions (Q_v) according to the first law may be expressed as follows:

$$Q_v = \Sigma(Nu)_P - \Sigma(Nu)_R$$

The term N refers to the amount of material, and the symbol u signifies the internal energy per unit quantity of material. The subscripts P and R refer to the products and reactants, respectively. Hence, it may be concluded that Q_v is equal to the change in internal energy. The heat of combustion under constant-volume conditions may also be described as the quantity of heat transferred from a calorimeter to the external surroundings when the termperature and volume of the combustion products are brought to the temperature and volume, respectively, of the gaseous mixture before burning.

2. The **heat value at constant pressure** (Q_p). For a constant-pressure process the first law may be expressed as

$$Q_p = \Sigma(Nu)_P - \Sigma(Nu)_R + pV_P - pV_R$$

Here the symbols p and V refer to the pressure and total volume, respectively. Usually in combustion reactions that part of the change in internal energy resulting from a volume change is small in comparison to the total change; hence it may usually be neglected. Assuming therefore that the internal energy change for a constant-volume reaction is approximately equal to that for a constant-pressure change. the following equation results:

$$Q_p = Q_v + p(V_P - V_R)$$

Since Q_v is equal to the change in internal energy, this relation may be changed to enthalpy values, from which it may be concluded that Q_v is equal to the change in enthalpy. The heat of combustion under constant pressure conditions may also be described as the heat transferred from a calorimeter when the pressure and temperature of the products are brought back to the pressure and temperature, respectively, of the gaseous mixture before burning.

If the reactants and products are assumed to be ideal gases, then the relation for (Q_p) may be expressed as follows, where ΔN represents the change in number of moles and R the universal gas constant:

$$Q_p = Q_v + \Delta N\,RT$$

From this relation the heat transferred (heat of combustion) at constant pressure may be found from the heat of reaction at constant volume, or vice versa, if the temperature and molar-volume change are known.

If there is no change of volume due to the combustion, the heat values Q_p and Q_v are the same. When there is a contraction of volume, Q_p exceeds Q_v by the heat equivalent of the work done on the gas during the contraction. For example, in the burning of CO according to the equation $CO + \frac{1}{2}O_2 = CO_2$, there is a contraction of ½ volume. Taking 62°F as the temperature, the volume of 1 lb CO at atmospheric pressure is 13.6 ft^3; hence the equivalent of the work done at atmospheric pressure is ½ × 13.6 × 2,116/778 = 18.5 Btu, which is about 0.4 percent of the heat value of CO. Since the difference between Q_p and Q_v is small in most fuels, it is usually neglected.

It is also to be noted that heat values vary with the initial temperature (which is also the final temperature), but the variation is usually negligible.

Heat Value per Unit Volume Since the consumption of a fuel gas is more easily measured by volume than by mass, it is convenient to express heat values in terms of volumes. For this purpose, a standard temperature and pressure must be assumed. It is customary to take atmospheric pressure (14.70 psi) as standard, but there is diversity of

Table 4.1.6 Heats of Combustion

Fuel	Chemical symbol	High heat value		Low heat value	
		Btu/lb	*Btu/ft^3	Btu/lb	*Btu/ft^3

Naphthalene (solid)	$C_{10}H_8$	17,310	. . . . .	13,110	

* Measured as a gas at 68°F and 14.70 psia. Multiply by 1.0154 for 60°F and 14.70 psia.

practice in the matter of a **standard temperature.** The temperature of 68°F (20°C) is generally accepted in metric countries and has been recommended by the American delegates to the meeting of the International Committee of Weights and Measures and also by the ASME Power Test Codes Committee. The American Gas Assoc. uses 60°F as the standard temperature of reference. Conversion of density and heat values from 68 to 60°F of dry (saturated) gas is obtained by multiplying by the factor 1.0154 (1.0212). Conversion of specific volumes of dry (saturated) gas is obtained by multiplying by the factor 0.9848 (0.9792).

If the gas is at some other pressure and temperature, say p_1 psia and T_1 °R, the heat value per cubic foot is found by multiplying the heat value per cubic foot under standard conditions by $35.9p_1/T_1$.

The heat values of a few of the more common fuels per pound and per cubic foot are given in Table 4.1.6.

Heat Value per Unit Volume of Mixture Let a denote the volume of air required for the combustion of 1 ft^3 of fuel gas and xa the value of air actually admitted, $(x - 1)a$ being therefore the excess. Then the volume of the mixture of fuel gas and air is $1 + xa$, and the quotient $Q/(1 + xa)$ may be called the heat value per cubic foot of mixture. This magnitude is useful in comparing the relative volumes of mixture required with different fuel gases. Thus a lean gas, as blast-furnace gas or producer gas, has a low heat value Q, but the value of a is correspondingly low. On the other hand, a rich gas, like natural gas, has a high heat value but requires a large volume of air for combustion (see Table 4.1.7).

Low and High Heat Values Any fuel containing hydrogen yields water as one product of combustion. At atmospheric pressure, the partial pressure of the water vapor in the resulting combustion gas mixture will usually be sufficiently high to cause water to condense out if the temperature is allowed to fall below 120 to 140°F. This causes liberation of the heat of vaporization of any water condensed. The low heat value is evaluated assuming no water vapor condensed, whereas the high heat value is calculated assuming all water vapor condensed.

To facilitate calculations of the temperature attained by combustion, it is desirable to make use of the **low heat value.** The necessity of taking into account the heat of vaporization of the water vapor and the difference between the specific heats of liquid water and of water vapor is thus avoided. The high heat of combustion exceeds the low heat of combustion by the difference between the heat actually given up on cooling the products to the initial temperature and that which would have been given up if the products had remained in the gaseous state. A bomb calorimeter (constant volume) gives practically correct values of the high heat value; a gas calorimeter (constant pressure) gives values which, for the usual fuels, may be incorrect by a fraction of 1 percent. The quantity to be subtracted from the high heat value to obtain the low heat value will vary with the composition of the fuel; an approximate value is $1{,}050m$, where m is the number of pounds of H_2O formed per pound of fuel burned.

In Germany, the low heat value of the fuel is used in calculating efficiencies of internal-combustion engines. In the United States, the high value is specified by the ASME Power Test Codes.

Heat of Formation The change in enthalpy resulting when a compound is formed from its elements isothermally and at constant pressure is numerically equal to, but of opposite sign to, the heat of formation, $\Delta H_f = -Q_f$. It is equal to the difference between the heats of combustion of the constituents forming the compound and the heat of combustion of the compound itself. The following values for heats of formation are in Btu per pound of the compound. The elements before the change and the compounds formed are assumed in their ordinary stable states at 65°F and 1 atm. A plus sign indicates heat evolved on forming the compound, a minus sign heat absorbed from the surroundings.

Fuels Methane, CH_4 (gas), 2,001.4; ethane, C_2H_6 (gas), 1,206.1; propane, C_3H_8 (vapor), 1,008.5; acetylene, C_2H_2 (gas), −3747; ethylene, C_2H_4 (gas), − 805.3; benzene, C_6H_6 (vapor), − 459; toluene, C_7H_8 (vapor), − 234.9; methyl alcohol, CH_3OH (liquid), 3,227.3; ethyl alcohol, C_2H_5OH (liquid), 2,623.3.

INTERNAL ENERGY AND ENTHALPY OF GASES

Table 4.1.8 gives the internal energy of various common gases in Btu/(lb · mol) measured above 520°R (60°F). The corresponding values of the enthalpy are obtained by adding the value of Apv from the last column.

TEMPERATURE ATTAINED BY COMBUSTION

Excluding the effect of dissociation, the temperature attained at the end of combustion may be calculated by a simple energy balance. The heat of combustion less the heat lost by conduction and radiation during the process is equal to the increase in internal energy of the products mixture if the combustion is at constant volume; or, if the combustion is at constant pressure, the difference is equal to the increase in enthalpy of the products mixture.

EXAMPLE. To calculate the temperature of combustion of a fuel gas having the composition $H_2 = 0.50$, $CO = 0.46$, $CO_2 = 0.04$. The gas is burned with 15 percent excess air at constant volume, and the initial temperature is 62°F; i.e., $T = 522$°R.

The volume compositions of the initial mixture of fuel gas and air and of the mixture of products are, respectively,

Initial: H_2, 0.50; CO, 0.46; CO_2, 0.04; O_2, 0.552; N_2, 2.098
Products: H_2O, 0.50; CO_2, 0.50; O_2, 0.072; N_2, 2.098

Since a volume composition is also a mol composition, the products mixture may be regarded as made up of 0.5 mol each of H_2O and CO_2, 0.072 mol of O_2, and 2.098 mols of N_2. If values are taken from Tables 4.1.6 and 4.1.7, the heat generated by combustion of the fuel mixture is $0.50 \times 2 \times 51{,}593 + 0.46 \times 28 \times 4{,}346 = 107{,}569$ Btu. The internal energy u of the products mixture at $T = 522$ is now calculated (Table 4.1.8). For 0.5 mol H_2O + 0.5 mol CO_2 + 0.072 mol 0_2 + 2.098 mol N_2 this is 6.1 + 6.95 + 0.72 + 20.34 = 34.11 Btu.

The energy u of the mixture is next calculated for various assumed temperatures, the proper values being taken from Table 4.1.8.

If the heat of combustion, 107,569 Btu, is entirely used in the increase of energy, the temperature attained lies somewhere between 5,000 and 5,100; by interpolation, the value 5,073° is obtained.

Loss of heat during combustion may readily be taken into account; thus if 10 percent of the heat of combustion is lost, the amount available for increasing the energy of the products is $107{,}569 \times 0.90 = 96{,}812$ Btu, and this increase gives $T_2 = 4{,}671$°. If the fuel is burned at constant pressure, Q_p is used instead of Q_v and values of h are determined from Table 4.1.8 instead of values of u.

EFFECT OF DISSOCIATION

The maximum temperature that can be obtained by the combustion of any fuel is limited by the dissociation of the products formed. The dissociation and equilibriums involved in high-temperature combustion are exceedingly complex, involving such chemical species as CO_2, CO, H_2O, H_2, H, OH, N_2, NO, N, O_2, and O. The equilibrium reached is a direct consequence of the second law of thermodynamics. However, the calculation of the equilibrium constant even for simple reactions is tedious. For all possible reactions $aA + bB \rightarrow cC + dD$ ($a, b, c, d \leq 2$), the excellent tables of the equilibrium constant k_p contained in the "American Institute of Physics Handbook," 3d edition, McGraw-Hill, pp. 4-31 and 4-32, are recommended to save time. Papers describing the calculation of k_p for multicomponent reacting gases are contained in the first *ASME Symposium on Thermophysical Properties Proceedings.*

Calculated flame temperatures, allowing for dissociation, for gaseous fuels with stated amounts of air present are given in Table 4.1.9. The combustion is assumed to be adiabatic and at 14.7 lb/in^2 absolute.

In the case of **explosion** in the **internal-combustion engine,** the figures in Table 4.1.9 will be somewhat changed. The effect of compression is to increase both the initial temperature and the initial pressure. The resulting increase in the explosion temperature will tend to increase the dissociation; the increase of pressure will tend to reduce it. The net effect will be a small reduction.

COMBUSTION OF LIQUID FUELS

For properties of fuel oils, heat values, etc., see Sec. 7. Calculations for the burning of liquid fuels are fundamentally the same as for gaseous fuels. Liquid fuels are almost always gasified before or during actual combustion.

COMBUSTION OF SOLID FUELS

For **properties of solid fuels,** heat values, etc., see Sec. 7.

Air Required for Combustion Let c, h, and o, denote, respectively, the parts of carbon, hydrogen, and oxygen in 1 lb of the fuel. Then the **minimum amount of oxygen** required for complete combustion is $2.67c + 8h - o$ lb, and the **minimum quantity of air** required is $a = (2.67c + 8h - o)/0.23 = 11.6[c + 3(h - o/8)]$ lb.

With air at 62°F and at atmospheric pressure, the minimum volume of air required is $v_m = 147[c + 3(h - o/8]$ ft^3. In practice, an excess of air over that required for combustion is admitted to the furnace. The actual quantity admitted per pound of fuel may be denoted by xa. Then x = amount admitted ÷ minimum amount.

Combustion Products If v_m is the minimum volume of air required for complete combustion and xv_m the actual volume supplied, then the products will contain per pound of fuel, $O_2 = 0.21v_m(x - 1)$ ft^3, $N_2 = 0.79xv_m$ ft^3.

From the reaction equation $C + O_2 = CO_2$, the volume of CO_2 formed is equal to the volume of oxygen required for the carbon constituent alone; hence volume of $CO_2 = 0.21v_m c/[c + 3(h - 0.125o)]$.

Of the *dry* gaseous products (i.e., without water), the CO_2 content by volume is therefore given by the expression

$$CO_2 = 0.21c/[xc + (x - 0.21)3(h - 0.125o)]$$

The combined CO_2 and O_2 content is

$$CO_2 + O_2 = 0.21\left\{1 - 0.79 \Big/ \left[\frac{x + cx}{3(h - 0.125o) - 0.21}\right]\right\}$$

If the fuel is all carbon, the combined CO_2 and O_2 is by volume 21 percent of the gaseous products. The more hydrogen contained in the fuel, the smaller is the $CO_2 + O_2$ content. The CO_2 content depends in the first instance on the excess of air. Thus, for pure carbon, it is $CO_2 = 0.21/x$.

The excess of air may be calculated from the composition of the gases and that of the fuel. Thus

$$x = 0.21\left[\frac{c}{[CO_2]} + 3(h - 0.125o)\right] \Big/ [c + 3(h - 0.125o)]$$

in which $[CO_2]$ denotes the percent by volume of the CO_2 in the dry gas.

The temperature of combustion is calculated by the same method as for gaseous fuels.

Loss due to Incomplete Combustion The loss due to incomplete combustion of the carbon in the fuel, in Btu/lb of fuel, is

$$L = 10{,}136\text{C} \times \text{CO}/(\text{CO} + \text{CO}_2)$$

where 10,136 = difference in heat evolved in burning 1 lb of carbon to CO_2 and to CO; CO and CO_2 = percentages by volume of carbon monoxide and carbon dioxide as found by analysis; and C = fraction of quantity of carbon in the fuel which is actually burned and passes up the stack, either as CO or CO_2. The presence of 1 percent of CO in the flue gases will represent a decrease in the boiler efficiency of 4.5 percent. An additional loss is caused by passage through the grate to the ashpit of any unburned or partly burned fuel.

It is generally assumed that high CO_2 readings are indicative of good combustion and, hence, of high efficiencies. Such readings are not satisfactory when considered apart from the CO determination. The best percentage of CO_2 to maintain varies with different fuels and is lower for those with a high hydrogen content than for fuel mainly composed of carbon.

Hydrogen in a fuel increases the nitrogen content of the flue gases. This is due to the fact that the water vapor formed by the combustion of hydrogen will condense at the temperature at which the analysis is made, while the nitrogen which accompanied the oxygen maintains its gaseous form and passes in that form into the sampling apparatus. For this reason, where higbly volatile coals containing considerable hydrogen are burned, the flue gas contains an apparently increased amount of nitrogen. The effect is even more pronounced when burning gaseous or liquid hydrocarbon fuels.

The amount of flue gases per pound of fuel, including moisture formed by the hydrogen component, is approximately $3.02[N/(CO_2 + CO)]C + (1 - A)$, where A = percent of ash found in test. The quantity of dry flue gases per pound of fuel may be approximated from the formula $W_2 = C[11CO_2 + 8O + 7(CO + N)]/3(CO_2 + CO)$. In these formulas. the amount of gas is per pound of dry or moist fuel as the percentage of C is referred to a dry or moist basis.

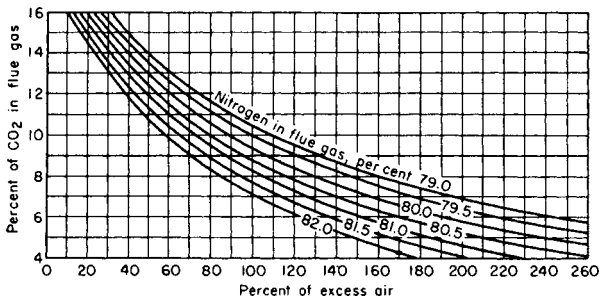

Fig. 4.1.37 Ratio of air supplied per pound of combustible to that theoretically required.

The ratio of air suppplied per pound of fuel to the air theoretically required is

$$\frac{W_1}{W} = \frac{3.02C[N/(CO_2 + CO)]}{34.56(C/3 + H - O/8)}$$

The ratio of air supplied per pound of combustible to that theoretically required is $N/[N - 3.782(O - \frac{1}{2}CO),]$ on the assumption that all the nitrogen in the flue gas comes from the air supplied. Figure 4.1.37 gives the value of this ratio for varying flue-gas analyses where there is no CO present.

For petroleum fuels with hydrogen content from 9 to 16 percent, the excess air can be determined from the CO_2 content of the flue gases (with no CO present) by the use of Fig. 4.1.38. The curves are based on the assumption of 0.4 percent sulfur in the oil.

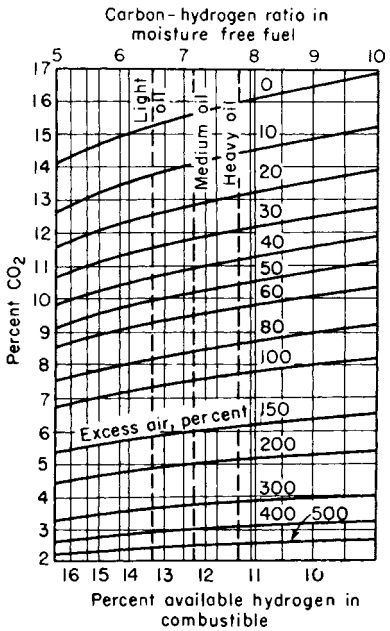

Fig. 4.1.38 Relation of CO_2 to excess air for fuels.

4.2 THERMODYNAMIC PROPERTIES OF SUBSTANCES

by Peter E. Liley

NOTE: Thermodynamic properties of a variety of other specific materials are listed also in Secs. 4.1, 6.1, and 9.8.

* Values rounded off from Chappell and Cockshutt, Nat. Res. Counc. Can. Rep. NRC LR 759 (NRC No. 14300), 1974. This source tabulates values of seven thermodynamic functions at 1-K increments from 200 to 2,200 K in SI units and at other increments for two other unit systems. An earlier report (NRC LR 381, 1963) gives a more detailed description of an earlier fitting from 200 to 1,400 K. In the above table h = specific enthalpy, kJ/kg, and $\Psi_2 - \Psi_1 = \log (P_2/P_1)$, for an isentrope. In terms of the Keenan and Kaye function ϕ, $\Psi = [\log (e/R)]\phi$.

Table 4.2.25 Color Scale of Temperature for Iron or Steel

Color	Temperature °F	Temperature K
Dark blood red, black red	1,000	810
Dark red, blood red, low red	1,050	840
Dark cherry red	1,175	910
Medium cherry red	1,250	950
Cherry, full red	1,375	1,020
Light cherry, light red	1,550	1,120
Orange, free scaling heat	1,650	1,170
Light orange	1,725	1,210
Yellow	1,825	1,270
Light yellow	1,975	1,350
White	2,200	1,475

Table 4.2.26 Melting Points of Refractory Materials

Material	Temperature °F	Temperature K
Aluminum nitride, AIN	4,060	2,500
Aluminum oxide, Al_2O_3	3,720	2,320
Aluminum oxide–beryllium oxide, Al_2O_3-BeO	3,400	2,140
Beryllium carbide, Be_2C	3,810	2,370
Beryllium nitride, Be_3N_4	4,000	2,480
Beryllium oxide, BeO	4,570	2,790
Beryllium silicide, $2BeO \cdot SiO_2$	3,630	2,270
Borazon, BN	5,430	3,270
Calcia (lime), CaO	4,660	2,840
Graphite, C	6,700	3,980
Hafnia, HfO_2	5,090	3,090
Magnesia, MgO	5,070	3,070
Niobium carbide, NbC	6,330	3,770
Silica, SiO_2	3,110	1,980
Silicon carbide, SiC	3,990	2,470
Thoria, ThO_2	5,830	3,490
Titanium carbide, TiC	5,680	3,410
Zirconium aluminide, $ZrAl_2$	3,000	1,920
Zirconium beryllide, $ZrBe_{13}$	3,180	2,020
Zirconium carbide, ZrC	6,400	3,810
Zirconium disilicide, $ZrSi_2$	3,090	1,970
Zirconium nitride, ZrN	5,400	3,260
Zirconium oxide, ZrO_2	4,900	2,980
Zirconium silicides, Zr_3Si_2, Zr_4Si_3, Zr_6Si_5	≃4,050	≃2,500

Table 4.2.27 Mean Specific Heats of Various Solids (32–212°F, 273–373 K)

Solid	c, Btu/(lb · °F)	c, kJ/(kg · K)
Alumina	0.183	0.77
Asbestos	0.20	0.84
Ashes	0.20	0.84
Bakelite	≃0.35	1.50
Basalt (lava)	0.20	0.84

4.3 RADIANT HEAT TRANSFER

by Hoyt C. Hottel, Adel F. Sarofim, and James J. Noble

REFERENCE: Baukal, "The John Zink Combustion Handbook," CRC Press. Blokh, "Heat Transfer in Steam Boiler Furnaces," Taylor & Francis. "Radiative Heat Transfer," 2d ed., Academic Press, 2003. Noble, *Int. J. Heat Mass Transfer*, **18,** 1975, pp. 261–269. Siegel and Howell, "Thermal Radiation Heat Transfer," 4th ed., Taylor & Francis. Stultz and Kitto, "Steam," 41st ed., Babcock and Wilcox. Hottel and Sarofim, "Radiative Transfer," McGraw-Hill.

A heated body loses energy continuously by radiation, at a rate dependent on the shape, the size, and, particularly, the temperature of the body. In contrast to conductive energy transport, such emitted radiation is capable of passage to a distant body, where it may be absorbed, reflected, scattered, or transmitted.

Consider a pencil of radiation, defined as all the rays passing through each of two small, widely separated areas dA_1 and dA_2. The rays at dA_1 will have a solid angle of divergence $d\Omega_1$; equal to the apparent area of dA_2 viewed from dA_1, divided by the square of the separating distance. Let the normal to dA_1 make the angle θ_1 with the pencil. The flux density q [energy/(time)(area normal to beam)] per unit solid angle of divergence is called the **intensity *I*,** and the flux dQ_1 (energy/time) through area dA_1 (of apparent area $dA_1 \cos\theta_1$ normal to the beam) is therefore given by

$$dQ_1 = dA_1 \cos\theta_1 q_1 = I\, dA_1 \cos\theta_1\, d\Omega_1 \tag{4.3.1}$$

The intensity *I* along a pencil, in the absence of absorption or scatter is constant (unless the beam passes into a medium of different refractive index n; $I_1/n_1^2 = I_2/n_2^2$). The **emissive power*** of a surface is the flux density [energy/(time)(surface area)] due to emission from it throughout a hemisphere. If the intensity I of emission from a surface is independent of the angle of emission, Eq. (4.3.1) may be used to show that the surface emissive power is πI, though the emission is throughout 2π steradians.

BLACKBODY RADIATION

Engineering calculations of thermal radiation from surfaces are best keyed to the radiation characteristics of the **blackbody,** or **ideal radiator.** The characteristic properties of a blackbody are that it absorbs all the radiation incident on its surface and that the quality and intensity of the radiation it emits are completely determined by its temperature. The total radiative flux throughout a hemisphere from a black surface of area A and absolute temperature T is given by the **Stefan-Boltzmann law:** $Q = A\sigma T^4$ or $q = \sigma T^4$. The Stefan-Boltzmann constant σ has the value 5.67×10^{-8} W/m^2(K)^4, 0.1713×10^{-8} Btu/(ft)^2(h)(°R)^4 or 1.356×10^{-12} cal/(cm)^2(s)(K)^4. From the above definition of emissive power, σT^4 is the total emissive power of a blackbody, called E; and the intensity I_B of emission from a blackbody is E/π, or $\sigma T^4/\pi$.

The spectral distribution of energy flux from a blackbody is expressed by Planck's law

$$E_\lambda\, d\lambda = \frac{2\pi h c^2 n^2 \lambda^{-5}}{e^{hc/(k\lambda T)} - 1}\, d\lambda \equiv \frac{n^2 c_1 \lambda^{-5}}{e^{c_2/(\lambda T)} - 1} \tag{4.3.2}$$

wherein $E_\lambda\, d\lambda$ is the hemispherical flux density in W/m^2 lying in the wavelength range λ to $\lambda + d\lambda$; h is Planck's constant, 6.6262×10^{-34} J · s; c is the velocity of light in vacuo, 2.9979×10^8 m/s; k is the Boltzmann constant, 1.3807×10^{-23} J/K; λ is the wavelength measured in vacuo, m; n is the refractive index of the emitter; c_1 and c_2, the first and second Planck's law constants, are 3.7418×10^{-16} W · m^2 and 1.4388×10^{-2} m · K. To show how E_λ varies with wavelength or temperature, Planck's law may be cast in the form

$$\frac{E_\lambda}{n^2 T^5} = \frac{c_1 (\lambda T)^{-5}}{e^{c_2/(\lambda T)} - 1} \tag{4.3.3}$$

i.e., when $n \cong 1$ (e.g., in a gas), E_λ/T^5 is a unique function of λT. And E_λ is a maximum at $\lambda T = 2{,}898$ μm · K (Wien's displacement law). A more useful displacement law: Half of blackbody radiation lies on either side of $\lambda T = 4{,}107$ μm · K. Another: The maximum intensity per unit fractional change in wavelength *or* frequency is at $\lambda T = 3{,}670$ μm · K. Integration of E_λ over λ shows that the fraction f of blackbody radiation lying at wavelengths below λ depends only on λT. Values of f versus λT appear in Table 4.3.1. A twofold range of λT geometrically centered on $\lambda T = 3{,}670$ μm · K spans about half the energy.

A limiting form of the Planck equation as $\lambda T \to 0$ is $E_\lambda = n^2 c_1 \lambda^{-5} e^{-c_2/(\lambda T)}$, the Wien equation, less than 1 percent in error when λT is less than 3,000 μm · K. This is useful for optical pyrometry (red screen $\lambda = 0.65$ μm) when $T < 4{,}800$ K.

Table 4.3.1 Fraction *f* of Blackbody Radiation below λT
λT= μm · K

λT	1,200	1,600	1,800	2,000	2,200	2,400	2,600	2,800

f	0.914	0.945	0.963	0.986	0.999			

RADIATIVE EXCHANGE BETWEEN SURFACES OF SOLIDS

The ratio of the total radiating power of a real surface to that of a black surface at the same temperature is called the **emittance** of the surface (for a perfectly plane surface, the **emissivity**), designated by ε. Subscripts λ, θ, and n may be assigned to differentiate monochromatic, directional, and surface-normal values, respectively, from the total hemispherical value. If radiation is incident on a surface, the fraction absorbed is called the **absorptance (absorptivity),** a term in which two subscripts may be appended, the first to identify the temperature of the surface and the second to identify the quality of the incident radiation. According to **Kirchhoff's law,** the emissivity and absorptivity of a surface *in surroundings at its own temperature* are the same, for both monochromatic and total radiation. When the temperatures of the surface and its surroundings differ, the total emissivity and absorptivity of the surface are found often to be different, but because absorptivity is substantially independent of irradiation density, the monochromatic emissivity and absorptivity of surfaces are for all practical purposes the same. The difference between total emissivity and absorptivity depends on the variation, with wavelength, of ε_λ and on the difference between the emitter temperature and the effective source temperature.

Consider radiative exchange between a body of area A_1 and temperature T_1 and its black surroundings at T_2. The net interchange is given by

$$\dot{Q}_{1=2} = A_1 \int_0^\infty [\varepsilon_\lambda E_\lambda(T_1) - \alpha_\lambda E_\lambda(T_2)]\, d\lambda$$
$$= A_1(\varepsilon_1 \sigma T_1^4 - \alpha_{12} \sigma T_2^4) \tag{4.3.4}$$

* Variously called, in the literature, **emittance, total hemispherical intensity, radiant flux density** or **exitance.**

where

$$\varepsilon_1 = \int_0^1 \varepsilon_\lambda \, df_{\lambda T_1} \qquad \text{and} \qquad \alpha_{12} = \int_0^1 \varepsilon_\lambda \, df_{\lambda T_2} \tag{4.3.5}$$

i.e., ε_1 (or α_{12}) is the area under a curve of ε_λ versus f, read as a function of λT at T_1 (or T_2) from Table 4.3.1. If ε_λ does not change with wavelength, the surface is called **gray,** and $\varepsilon_1 = \alpha_{12} = \varepsilon_\lambda$. A selective surface is one whose ε_λ changes dramatically with wavelength. If this change is monotonic, ε_1, and α_{12} are, according to Eqs. (4.3.4) and (4.3.5), markedly different when the absolute temperature ratio is far from 1; e.g., when $T_1 = 293$ K (ambient temperature) and $T_2 = 5{,}800$ K (effective solar temperature), $\varepsilon_1 = 0.9$ and $\alpha_{12} = 0.1$–0.2 for a white paint, but ε_1 can be as low as 0.12 and α_{12} above 0.9 for a thin layer of copper oxide on bright aluminum, or of chromic oxide on bright nickel.

Although values of emittances and absorptances depend in very complex ways on the real and imaginary components of the refractive index and on the geometric structure of the surface layer, some generalizations are possible.

Polished Metals (1) ε_λ is quite low in the infrared and, for $\lambda > 8$ μm, can be adequately approximated by $0.00365\sqrt{r/\lambda}$, where r is the resistivity in ohm · cm and λ is in micrometres; at shorter wavelengths, ε_λ increases and, for many metals, has values of 0.4 to 0.8 in the visible (0.4–0.7 μm). ε_λ is approximately proportional to the square root of the absolute temperature ($\varepsilon_\lambda \propto \sqrt{r}$ and $r \propto T$) in the far infrared ($\lambda > 8$ μm), is temperature insensitive in the near infrared (0.7–1.5 μm) and, in the visible, decreases slightly as temperature increases. (2) Total emittance is substantially proportional to absolute temperature; at moderate temperature, $\varepsilon_n = 0.58T\sqrt{r_0/T_0}$, where T is in kelvins. (3) Total absorptance of a metal at T_1 for radiation from a black or gray source at T_2 is equal to the emissivity evaluated at the geometric mean of T_1 and T_2. (4) The ratio of hemispherical to normal emittance (absorptance) varies from 1.33 at very lower ε's (α's) to about 1.03 at an ε (α) of 0.4.

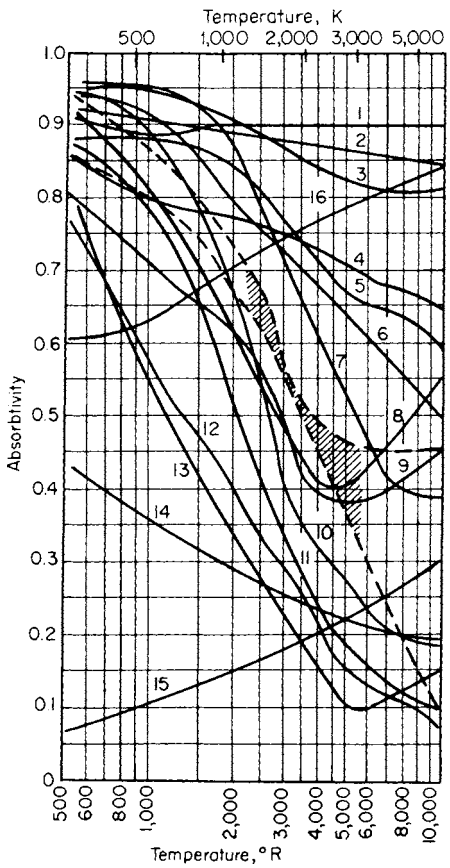

Fig. 4.3.1 Variation of absorptivity with temperature of radiation source. (1) Slate composition roofing; (2) linoleum, red-brown; (3) asbestos slate (asbestos use is obsolete, but may be encountered in existing construction); (4) soft rubber, gray; (5) concrete; (6) porcelain; (7) vitreous enamel, white; (8) red brick; (9) cork; (10) white Dutch tile; (11) white chamotte; (12) MgO, evaporated; (13) anodized aluminum; (14) aluminum paint; (15) polished aluminum; (16) graphite. The two dashed lines bound the limits of data for gray paving brick, asbestos paper (asbestos use is obsolete, but may be encountered in existing construction), wood, various cloths, plaster of paris, lithopone, and paper.

Unless extraordinary pains are taken to prevent oxidation, however, a metallic surface may exhibit several times the emittance or absorptance of a polished specimen. The emittance of iron and steel, for example, varies widely with degree of oxidation and roughness—clean metallic surfaces have an emittance of from 0.05–0.45 at ambient temperatures to 0.4–0.7 at high temperatures; oxidized and/or rough surfaces range from 0.6–0.95 at low temperatures to 0.9–0.95 at high temperatures.

Refractory Materials Grain size and concentration of trace impurities are important. (1) Most refractory materials have an ε_λ of 0.8 to 1.0 at wavelengths beyond 2 to 4 μm; ε_λ decreases rapidly toward shorter wavelengths for materials that are white in the visible but retains its high value for black materials such as FeO and Cr_2O_3. Small concentrations of FeO and Cr_2O_3 or other colored oxides can cause marked increases in the emittance of materials that are normally white. ε_λ for refractory materials varies little with temperature. (2) Refractory materials generally have a total emittance which is high (0.7 to 1.0) at ambient temperatures and decreases with increase in temperature; a change from 1,000 to 1,600°C may cause a decrease in ε of one-fourth to one-third. (3) The emittance and absorptance increase with increase in grain size over a grain-size range of 1–200 μm. (4) The ratio $\varepsilon/\varepsilon_n$ of hemispherical to normal emissivity of polished surfaces varies with refractive index from 1 at $n = 1$ to 0.95 at $n = 1.5$ (common glass) and back to 0.98 at $n = 3.5$. (5) The ratio $\varepsilon/\varepsilon_n$ for a surface composed of particulate matter which scatters isotropically varies with ε from 1 when $\varepsilon = 1$ to 0.8 when $\varepsilon = 0.07$. (6) The total absorptance shows a decrease with increase in temperature of the radiation source similar to the decrease in emittance with increase in the specimen temperature. Figure 4.3.1 shows the effect of the temperature of the radiation source on the absorptance of surfaces of various materials at room temperature. It will be noted that polished aluminum (line 15) and anodized aluminum (line 13), representative of metals and nonmetals, respectively, respond oppositely to a change in the temperature of the radiation source. The absorptance of surfaces for sunlight may be read from the right of Fig. 4.3.1, assuming sunlight to consist of blackbody radiation from a source at 10,440°R (5,800 K).

When T_2 is not too different from T_1, α_{12} may be expressed as $\varepsilon_1(T_2/T_1)^n$, with n determined from Fig. 4.3.1. For this case, Eq. (4.3.4) becomes

$$\dot{Q}_{1,\text{net}} = \sigma A_1 \varepsilon_{AV}(1 + n/4)(T_1^4 - T_2^4) \tag{4.3.6}$$

where ε_{AV} is evaluated at the arithmetic mean of T_1 and T_2.

Table 4.3.2 gives the emittance of various surfaces and emphasizes the variation possible in a single material. The values in the table apply, with a few exceptions, to normal radiation from the surface.

For opaque materials, the **reflectance** ρ is the complement of the absorptance. The directional distribution of the reflected radiation depends on the material, its degree of roughness or grain size, and if a metal, its state of oxidation. Polished surfaces of homogeneous materials reflect specularly. In contrast, the intensity of the radiation reflected from a **perfectly diffuse,** or **Lambert,** surface is independent of direction. The directional distribution of reflectance of many oxidized metals, refractory materials, and natural products approximates that of a perfectly diffuse reflector. A better model, adequate for many calculational purposes, is achieved by assuming that the total reflectance ρ is the sum of diffuse and specular components ρ_D and ρ_S (Hottel and Sarofim, p. 180).

Black Surface Enclosures When several surfaces are present, the need arises for evaluating a geometric factor F, called the **direct-view factor.** Restriction is temporarily to black surfaces, the intensity from which is independent of angle of emission. Define F_{12} as the fraction of

Table 4.3.2 Emissivity of Surfaces

Surface	Temp.,* °C	Emissivity*
Metals and their oxides		
Aluminum:		
Highly polished	230–580	0.039–0.057

Table 4.3.2 Emissivity of Surfaces (*Continued*)

Surface	Temp.,* °C	Emissivity*
Refractories, building materials, paints, misc.		
Alumina	260–680	0.6–0.33
Alumina, 50-μm grain size	1,010–1,570	0.39–0.28
Alumina-silica, cont'g	1,010−1,570	
0.4% Fe_2O_3		0.61–0.43
1.7% Fe_2O_3		0.73–0.62
2.9% Fe_2O_3		0.78–0.68
Al paints (vary with amount of lacquer body, age)	100	0.27–0.67
Asbestos	40–370	0.93–0.95
Calcium oxide	750–1,100	0.29–0.28
Candle soot; lampblack-waterglass	20–370	0.95 ± 0.01
Carbon plate, heated	130–630	0.81–0.79
Ferric oxide (Fe_2O_3)	500–900	0.8–0.43
Magnesium oxide, 1 μm	260–760	0.67–0.41
Oil layers		
Lube oil, 0.01 in on pol. Ni	20	0.82
Linseed, 1–2 coats on A1	20	0.56–0.57
Rubber, soft gray reclaimed	24	0.86
Silica, 3 μm	260–740	0.7–0.5
Misc. I: shiny black lacquer, planed oak, white enamel, serpentine, gypsum, white enamel paint, roofing paper, lime plaster, black matte shellac	21	0.87–0.91
Misc. II: glazed porcelain, white paper, fused quartz, polished marble, rough red brick, smooth glass, hard glossy rubber, flat black lacquer, water, electrographite	21	0.92–0.96

* When two temperatures and two emissivities are given they correspond, first to first and second to second, and linear interpolation is suggested.

the radiation leaving surface A_1 in all directions which is intercepted by surface A_2. Since the net interchange between A_1 and A_2 must be zero when their temperatures are alike, it follows that $A_1F_{12} = A_2F_{21}$. From the definition of F and Eq. (4.3.1),

$$A_1F_{12} = \int_{A1}\int_{\Omega} \frac{dA_1 \cos\theta_1\, d\Omega_1}{\pi} = \int_{A1}\int_{A2} \frac{dA_1 \cos\theta_1\, dA_2 \cos\theta_2}{\pi r^2} \tag{4.3.7}$$

where $dA\cos\theta$ is the projection of dA normal to r, the line connecting dA_1 and dA_2. The product A_1F_{12}, having the dimensions of area, will be called the **direct-interchange area** and be designated by $\overline{s_1s_2}$, sometimes for brevity by $\overline{12}$ ($\equiv \overline{21}$). Clearly, $\overline{11} + \overline{12} + \overline{13} + \cdots = A_1$; and when A_1 cannot "see" itself, $\overline{11} = 0$. Values of F or $\overline{ss}$ have been calculated for various surface arrangements.

Direct-View Factors and Direct Interchange Areas

CASE 1. Directly opposed parallel rectangles of equal dimensions, and with lengths of sides X and Y divided by separating distance z:

$$\overline{s_1s_2}\ (\equiv A_1F_{12} \equiv A_2F_{21}) = \frac{z^2}{\pi}\left[\ln\left\{\frac{(1+X^2)(1+Y^2)}{1+X^2+Y^2}\right\}^{1/2} + X\sqrt{1+Y^2}\tan^{-1}\frac{X}{\sqrt{1+Y^2}} + Y\sqrt{1+X^2}\tan^{-1}\frac{Y}{\sqrt{1+X^2}} - X\tan^{-1}X - Y\tan^{-1}Y\right]$$

See also Fig. 4.3.2.

CASE 2. Parallel circular disks with centers on a common normal and with radii R_1 and R_2 divided by separating distance z:

$$\overline{s_1s_2}\ (\equiv A_1F_{12} \equiv A_2F_{21}) = \frac{\pi z^2}{2}\left[1 + R_1^2 + R_2^2 - \sqrt{(1+R_1^2+R_2^2)^2 - 4R_1^2R_2^2}\right]$$

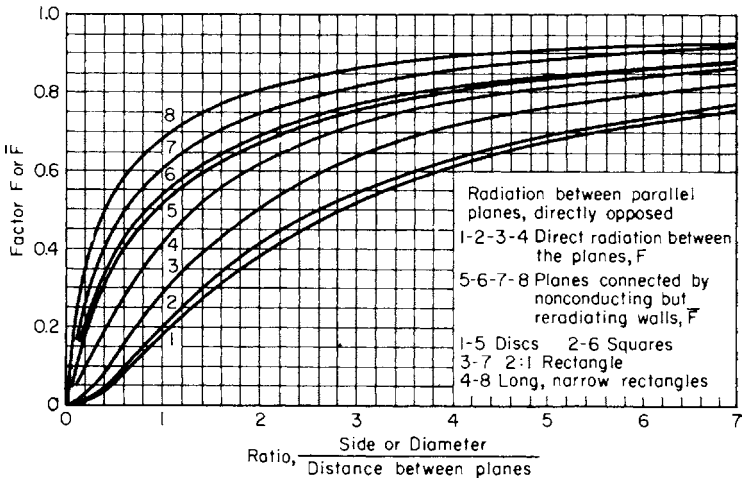

Fig. 4.3.2 Variation of the factor F or $\overline{F}$ for parallel planes directly opposed.

CASE 3. Rectangles in perpendicular planes of area A_1 and A_2, with a common edge l and with other dimension divided by $l = W_1$ and W_2:

$$\overline{s_1 s_2}\ (\equiv A_1 F_{12} \equiv A_2 F_{21})$$
$$= \frac{l^2}{\pi}\left(\frac{1}{4}\ln\left\{\frac{(1+W_1^2)(1+W_2^2)}{1+W_1^2+W_2^2}\left[\frac{W_1^2(1+W_1^2+W_2^2)}{(1+W_1^2)(W_1^2+W_2^2)}\right]^{W_1^2}\right.\right.$$
$$\left.\left.\times\left[\frac{W_2^2(1+W_1^2+W_2^2)}{(1+W_2^2)(W_1^2+W_2^2)}\right]^{W_2^2}\right\}\right.$$
$$\left. + W_1\tan^{-1}\frac{1}{W_1} + W_2\tan^{-1}\frac{1}{W_2} - \sqrt{W_1^2+W_2^2}\tan^{-1}\frac{1}{\sqrt{W_1^2+W_2^2}}\right)$$

CASE 4. Circular cylinder of radius r_1 surrounded by cylinder of radius r_2, both of equal length l and on a common axis:

$$A_1 = 2\pi r_1 l \qquad A_2 = 2\pi r_2 l$$

Let $r_1/l = R_1$; $r_2/l = R_2$; $[1/R_1^2 - (R_2/R_1)^2 + 1] = B$; $[1/R_1^2 + (R_2/R_1)^2 + 1] = D$; and $r_2/r_1 = R$.

$$\overline{s_1 s_2}\ (\equiv A_1 F_{12} \equiv A_2 F_{21})$$
$$= l^2\left\{R_1^2\left[\sqrt{(D+2)^2 - 4R^2}\cos^{-1}\frac{B}{DR} + B\sin^{-1}\frac{1}{R} - \frac{\pi}{2}D\right]\right.$$
$$\left. + 2R_1\left(\pi - \cos^{-1}\frac{B}{D}\right)\right\}$$

$$\overline{s_2 s_2}\ (\equiv A_2 F_{22}) = l^2 R_1\left\{2\pi(R-1) + 4\tan^{-1}(2R_1\sqrt{R^2-1})\right.$$
$$- \sqrt{4R^2 + \frac{1}{R_1^2}}\left(\frac{\pi}{2} + \sin^{-1}\frac{4(R^2-1) + 1/[R_1^2(1-2/R^2)]}{4(R^2-1) + 1/R_1^2}\right)$$
$$\left. + \frac{1}{R_1}\left[\sin^{-1}\left(1 - \frac{2}{R^2}\right) + \frac{\pi}{2}\right]\right\}$$

CASE 5. Two closed surfaces, one enclosing the other and neither having any negative curvature; A_1 is inside. Since $F_{12} = 1$,

$$\overline{s_1 s_2}\ (\equiv A_1 F_{12} \equiv A_2 F_{21}) \equiv A_1$$
$$F_{21} = \frac{A_1}{A_2} \qquad F_{22} = 1 - \frac{A_1}{A_2}$$

CASE 6. Sphere of total inside area A_T; radiative exchange between sphere segments of areas A_1 and A_2. Application of Eq. (4.3.7) shows that, independent of relative position,

$$\overline{s_1 s_2}\ (\equiv A_1 F_{12} \equiv A_2 F_{21}) = \frac{A_1 A_2}{A_T} \qquad F_{12} = \frac{A_2}{A_T}$$

CASE 7. Two dimensional surfaces A_1 and A_2 per unit length normal to cross section, with each area defined by the length of string, stretched on inside face, between ends (i.e., elimination of negative curvature). Graphical exact solution: $\overline{s_1 s_2}$ (per unit normal length) = sum of lengths of crossed stretched strings between ends of A_1 and A_2 minus sum of uncrossed strings, all divided by 2. If an obstruction lies between A_1 and A_2, there may be two sets of strings to represent views on both sides of the obstruction, with results added. The relations for cases 8, 9, and 10 are the results of three among many applications of this principle.

CASE 8. Exchange among inside surfaces of hollow triangular shape of infinite length and areas A_1, A_2, and A_3:

$$\overline{s_1 s_2}\ (\equiv A_1 F_{12} \equiv A_2 F_{21}) = \frac{A_1 + A_2 - A_3}{2} \qquad F_{12} = \frac{A_1 + A_2 - A_3}{2A_1}$$

CASE 9. Exchange between two long parallel circular tubes of diameter D and center-to-center distance C, having areas A_{1a} and A_{1b} per unit length:

$$\overline{s_{1a}s_{1b}}\ (\text{per unit length}) = D\left[\sin^{-1}\frac{D}{C} + \sqrt{\left(\frac{C}{D}\right)^2 - 1} - \frac{C}{D}\right]$$
$$F_{1a\to 1b} = \frac{1}{\pi}\left[\sin^{-1}\frac{D}{C} + \sqrt{\left(\frac{C}{D}\right)^2 - 1} - \frac{C}{D}\right]$$

CASE 10. Exchange between a row of tubes and a plane parallel to it. Consider a unit length along tube axes, with single tube area $A_{1a} = \pi D$ and associated plane area $A_p = C$. A tube sees two tubes and two plane areas:

$$A_{1a} = 2\overline{s_{1a}s_{1b}} + 2\overline{s_{1a}s_p}$$
$$\overline{s_{1a}s_p}\ (\equiv \overline{s_p s_{1a}} \equiv A_p F_{p1}) = \frac{A_{1a}}{2} - \overline{s_{1a}s_{1b}}$$

Substituting from previous example (case 9) yields

$$F_{p1} = 1 - \frac{D}{C}\left[\sin^{-1}\frac{D}{C} + \sqrt{\left(\frac{C}{D}\right)^2 - 1} - \frac{\pi}{2}\right]$$

The value from case 10 appears as line 1 of Fig. 4.3.3. The same figure gives the fraction going to the second row. Additional curves in Fig. 4.3.3 can be obtained by considering the refractory backing as radiatively adiabatic, i.e., by assuming that the radiation that is not absorbed directly is reflected or reradiated, undergoing the same fractional absorption as the incoming beam. In a furnace chamber one zone of which is one or two rows of tubes backed by a refractory, one may visualize the zone as a continuous plane of area A_p at a temperature T_T, the tube surface-temperature, and having an effective absorptivity or

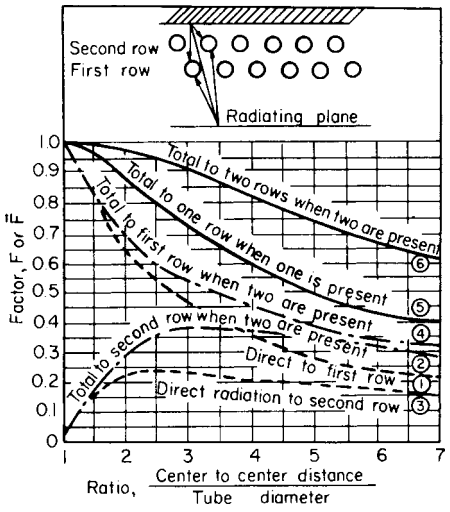

Fig. 4.3.3 Values of F or $\overline{F}$ for a plane parallel to rows of tubes.

emissivity $\varepsilon(\ = \mathcal{F}_{pT})$ that is equal to the value read from Fig. 4.3.3, line 5 or 6; in total exchange area nomenclature (see below), it is $(\overline{S_pS_T})_R/A_p$. Its complement is headed back toward the emitter, which is whatever faces the replaced tube zone—radiating gas or surfaces or a mixture of them.

When the tubes are gray,

$$\frac{A_p}{(\overline{S_pS_T})_R} = \frac{A_p}{(\overline{S_pS_T})_R}\Bigg)_{\substack{\text{black}\\\text{tubes}}} + \frac{\rho_T}{\varepsilon_T} \tag{4.3.8}$$

When $C/D = 2$, the treatment of a single tube row system with the tubes divided into two zones, front and rear half, reduces $(\overline{S_pS_T})_R$ or $\mathcal{F}_{pT}$ below the value given by Eq. (4.3.8) by only 1.7 percent (3 percent) when ε_T is 0.8 (0.6).

For other cases, see References.

The view factor F may often be evaluated from that for simpler configurations by the application of three principles: that of reciprocity, $A_iF_{ij} = A_jF_{ji}$; that of conservation, $\Sigma F_{ij} = 1$; and that due to Yamauti, showing that the exchange areas AF between two pairs of surfaces are equal when there is a one-to-one correspondence for all sets of symmetrically placed pairs of elements in the two surface combinations (Hottel and Sarofim, p. 60).

EXAMPLE. The exchange area between the two squares 1 and 4 of Fig. 4.3.4 is to be evaluated. The following exchange areas may be obtained from the values of F for common-side rectangles (case 3, direct-view factors): $\overline{13} = 0.24$, $\overline{24} = 2 \times 0.29 = 0.58$, $\overline{(1+2)(3+4)} = 3 \times 0.32 = 0.96$. Expression of $\overline{(1+2)(3+4)}$ in terms of its components yields $\overline{(1+2)(3+4)} = \overline{13} + \overline{14} + \overline{23} + \overline{24}$. And by the Yamauti principle $\overline{14} = \overline{23}$, since for every pair of elements in 1 and 4, there is a corresponding pair in 2 and 3. Therefore,

$$\overline{14} = [\overline{(1+2)(3+4)} - \overline{13} - \overline{24}]/2 = 0.07$$

Case 1 may be modified in the same way. Another example is the evaluation of AF for exchange between the outside of the smaller of two coaxial cylinders and the inside of the larger when they are *not* coextensive, given the view factor for coextensive cylinders (case 4).

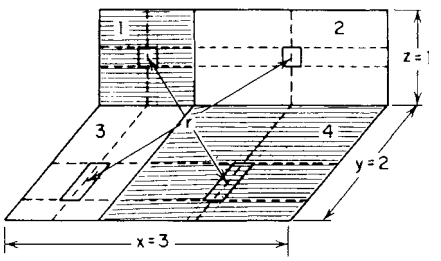

Fig. 4.3.4 Illustration of the Yamauti principle.

Enclosures Containing Gray Source and Sink Surfaces, Refractory Surfaces, and No Absorbing Gas (*Note:* An alternative formulation of the material to follow using matrix algebra is provided by Noble (see References) and in Sec. 5, "Perry's Handbook," 8th ed., McGraw-Hill. The matrix method readily addresses large systems using digital computation, and it can also be used to treat isotropic scatter in the gas volumes.) The calculation of interchange between a source and a sink under conditions involving successive multiple reflections from other source-sink surfaces in the enclosure, as well as reradiation from refractory surfaces, can become complicated. Let a **zone** of a furnace enclosure be an area small enough to make all elements of itself have substantially equivalent "views" of the rest of the enclosure. (In a furnace containing a symmetry plane, parts of a single zone would lie on either side of the plane.) Zones are of two classes, source-sink surfaces, designated by numerical subscripts and having areas $A_1, A_2, \ldots$ and emissivities $\varepsilon_1, \varepsilon_2, \ldots$; and surfaces at which the net radiant-heat flux is zero (fulfilled by the average refractory wall where difference between internal convection and external loss is minute compared with incident radiation), designated by letter subscripts starting with r, and having areas $A_r, A_s, \ldots$. It may be shown that the net radiation interchange between source-sink zones i and j is given by

$$\dot{Q}_{i=j} = \overline{S_iS_j}\sigma T_i^4 - \overline{S_jS_i}\sigma T_j^4 \tag{4.3.9}$$

The term $\overline{S_iS_j}$ is called the **total interchange area** shared by areas A_i and A_j and depends on the shape of the enclosure and the emissivity and absorptivity of the source and sink zones. It is sometimes called $A_i\mathcal{F}_{ij}$. Restriction here is to gray source-sink zones, for which $\overline{S_iS_j} = \overline{S_jS_i}$; the more general case is treated elsewhere (Hottel and Sarofim, Chaps. 3 and 5).

Evaluation of the $\overline{SS}$'s that characterize an enclosure involves solution of a system of radiation balances on the surfaces. If at a surface the total **leaving flux density,** emitted plus reflected, is denoted by W, radiation balances take the form for source-sink surface j:

$$A_j\varepsilon_jE_j + \rho_j\sum_i \overline{(ij)}W_i = A_jW_j \tag{4.3.10}$$

and for adiabatic surface r:

$$\sum_i \overline{(ir)}W_i = A_rW_r \tag{4.3.11}$$

where ρ is reflectance and the summation is over all surfaces in the enclosure. These equations apply to surfaces which emit and reflect diffusely (i.e., their leaving intensity W_i/π is independent of its direction). Most nonmetallic, tarnished, or rough metal surfaces correspond reasonably well to this restriction (but see p. 4-64). In matrix notation, Eqs. (4.3.10) and (4.3.11) become

$$\begin{bmatrix} \overline{11} - \dfrac{A_1}{\rho_1} & \overline{12} & \cdots & \overline{1r} & \overline{1s} & \cdots \\ \overline{12} & \overline{22} - \dfrac{A_2}{\rho_2} & \cdots & \overline{2r} & \overline{2s} & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ \overline{1r} & \overline{2r} & \cdots & \overline{rr} - A_r & \overline{rs} & \cdots \\ \overline{1s} & \overline{2s} & \cdots & \overline{rs} & \overline{ss} - A_s & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \end{bmatrix} \begin{bmatrix} W_1 \\ W_2 \\ \cdots \\ W_r \\ W_s \\ \cdots \end{bmatrix} = \begin{bmatrix} -\dfrac{A_1\varepsilon_1}{\rho_1}E_1 \\ -\dfrac{A_2\varepsilon_2}{\rho_2}E_2 \\ \cdots \\ 0 \\ 0 \\ \cdots \end{bmatrix} \tag{4.3.12}$$

This represents a system of simultaneous equations equal in number to the number of rows of the square matrix. Each equation consists, on the left, of the sum of the products of the members of a row of the square matrix and the corresponding members of the W-column matrix, and, on the right, of the member of that row in the third matrix. With the above set of equations solved for W_i, the net flux at any surface A_i is given by

$$\dot{Q}_{i,\text{net}} = \frac{A_1\varepsilon_i}{\rho_i}(E_i - W_i) \tag{4.3.13}$$

Refractory temperature is obtained from $W_r = E_r = \sigma T_r^4$.

The more generaj use of Eq. (4.3.12) is to obtain the set of total-interchange areas $\overline{SS}$ which constitute a complete description of the effect of shape, size, and emissivity on radiative flux, independent of the presence or absence of other transfer mechanisms. It may be shown that

$$\overline{S_iS_j} \equiv \overline{S_jS_i} \equiv A_i\mathcal{F}_{ij} = \frac{A_i\varepsilon_i}{\rho_i}\frac{A_j\varepsilon_i}{\rho_j}\left(-\frac{D_{ij}'}{D}\right) \tag{4.3.14}$$

where D is the determinant of the square coefficient matrix in Eq. (4.3.12) and D_{ij}' is the cofactor of its ith row and jth column, or -1^{i+j} times the minor of D formed by crossing out the ith row and jth column.

As an example, consider radiation between two surfaces A_1 and A_2 which together form a complete enclosure. Equation (4.3.12) takes the form

$$A_1\mathcal{F}_{12} = \frac{A_1\varepsilon_1}{\rho_1}\frac{A_2\varepsilon_2}{\rho_2}\frac{\overline{12}}{\begin{vmatrix} \overline{11} - \dfrac{A_1}{\rho_1} & \overline{12} \\ \overline{12} & \overline{22} - \dfrac{A_2}{\rho_2} \end{vmatrix}} \tag{4.3.15}$$

Only one direct-view factor F_{12} or direct exchange area $\overline{12}$ is needed because F_{11} equals $1 - F_{12}$ and F_{22} equals $1 - F_{21}$ or $1 - F_{12}A_1/A_2$. Then $\overline{11}$ equals $A_1 - \overline{12}$, and $\overline{22}$ equals $A_2 - \overline{21}$. With the above substitutions, Eq. (4.3.15) becomes

$$A_1\mathcal{F}_{12} = \frac{A_1}{1/F_{12} + 1/\varepsilon_1 - 1 + (A_1/A_2)(1/\varepsilon_2 - 1)} \tag{4.3.16}$$

Special cases include:

1. Parallel plates, large compared to clearance. Substitution of $F_{12} = 1$ and $A_1 = A_2$ gives

$$A_1\mathcal{F}_{12} = \frac{A_1}{1/\varepsilon_1 + 1/\varepsilon_2 - 1} \tag{4.3.17}$$

2. Sphere of area A_1 concentric with surrounding sphere of area A_2. $F_{12} = 1$. Then

$$A_1\mathcal{F}_{12} = \frac{A_1}{1/\varepsilon_1 + (A_1/A_2)(1/\varepsilon_2 - 1)} \tag{4.3.18}$$

3. Body of surface A_1 having no negative curvature, surrounded by very much larger surface A_2. $F_{12} = 1$ and $A_1/A_2 \to 0$. Then

$$\mathcal{F}_{12} = \varepsilon_1 \tag{4.3.19}$$

Many furnace problems are adequately handled by dividing the enclosure into but two source-sink zones A_1 and A_s, and any number of no-flux zones, A_r, A_s, ... For this case Eq. (4.3.14) yields

$$\frac{1}{\overline{S_1S_2}}\left(\equiv\frac{1}{\overline{S_2S_1}}\right) = \frac{1}{A_1}\left(\frac{1}{\varepsilon_1} - 1\right) + \frac{1}{A_2}\left(\frac{1}{\varepsilon_2} - 1\right) + \frac{1}{(\overline{S_1S_2})_B} \tag{4.3.20}$$

Here the expression $(\overline{S_1S_2})_B[\equiv(\overline{S_2S_1})_B]$ represents the total interchange area for the limiting case of a black source and black sink (the refractory emissivity is of no moment). The factor $(\overline{S_1S_2})_B/A_1$, called $\overline{F}_{12}$, is known exactly for a few geometrically simple cases and may be approximated for others. If A_1 and A_2 are equal parallel disks, squares, or rectangles, cpnnected by nonconducting but reradiating refractory walls, then $\overline{F}$ is given by Fig. 4.3.2, lines 5 to 8. If A_1 represents an infinite plane and A_2 is one or two rows of infinite parallel tubes in a parallel plane, and if the only other surface is a refractory surface behind the tubes, $\overline{F}_{12}$ is given by line 5 or 6 of Fig. 4.3.3. If an enclosure may be divided into several radiant-heat sources or sinks A_1, A_2, etc., and the rest of the enclosure (reradiating refractory surface) may be lumped together as A_r at a uniform temperature T_r, then the total interchange area for zone pairs in the black system is given by

$$(\overline{S_1S_2})_B(\equiv A_1\overline{F}_{12}) = \overline{12} + \frac{(\overline{1r})(\overline{r2})}{A_r - \overline{rr}} \tag{4.3.21}$$

For the two-source-sink-zone system to which Eq. (4.3.20) applies, Eq. (4.3.21) simplifies to $(\overline{S_1S_2})_B = \overline{12} + 1/[1/\overline{1r} + 1/(\overline{2r})]$; and if A_1 and A_2 each can see none of itself, there is further simplification to

$$(\overline{S_1S_2})_B = \overline{12} + \frac{1}{1/(A_1 - \overline{12}) + 1/(A_2 - \overline{12})} = \frac{A_1A_2 - (\overline{12})^2}{A_1 + A_2 - 2(\overline{12})} \tag{4.3.22}$$

which necessitates the evaluation of but one direct-view factor F.

Equation (4.3.20) covers many problems of radiant heat interchange between source and sink in furnace enclosures involving no radiating gas. The error due to single zoning of source and sink is small even if the "views" of the enclosure from different parts of each zone are quite different, provided the emissivity is fairly high; the error in $\overline{F}$ is zero if it is obtainable from Fig. 4.3.2 or 4.3.3, small if Eq. (4.3.21) is used and the variation in temperature over the refractory is small. Approach to any desired accuracy can be made by use of Eq. (4.3.14) with division of the surfaces into more zones.

From the definitions of F, $\overline{F}$, and $\mathcal{F}$ or of $\overline{ss}$, $(\overline{SS})_B$, and $\overline{SS}$ it is to be noted that

$$\left.\begin{aligned} F_{11} + F_{12} + \cdots + F_{1r} + F_{1s} + \cdots &= 1 \\ F_{11} + F_{12} + \cdots &= 1 \\ \mathcal{F}_{11} + \mathcal{F}_{12} + \cdots &= \varepsilon_1 \end{aligned}\right\}$$

$$\overline{s_1s_2} + \overline{s_1s_2} + \cdots + \overline{s_1s_r} + \overline{s_1s_s} + \cdots = A_1$$

or

$$(\overline{S_1S_1})_B + (\overline{S_1S_2})_B + \cdots = A_1$$

$$\overline{S_1S_1} + \overline{S_1S_2} + \cdots = A_1\varepsilon_1$$

EXAMPLE. A furnace chamber of rectangular parallelpipedal form is heated by the combustion of gas inside vertical radiant tubes lining the side walls. The tubes are on centers 2.4 diameters apart. The stock forms a continuous plane on the hearth. Roof and end walls are refractory. Dimensions are shown in Fig. 4.3.5. The radiant tubes and stock are gray bodies having emissivities 0.8 and 0.9, respectively. What is the net rate of heat transmission to the stock by radiation when the mean temperature of the tube surface is 1,500°F (1,089 K) and that of the stock is 1,200°F (922 K)?

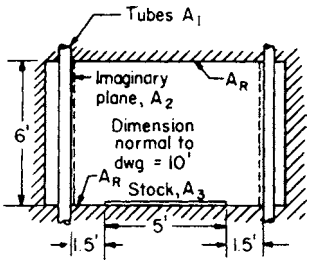

Fig. 4.3.5 Dimensions of a furnace chamber.

This problem must be broken up into two parts, first considering the walls with their refractory-backed tubes. To imaginary planes A_2 of area 6×10 ft and located parallel to and inside the rows of radiant tubes, the tubes emit radiation $\sigma T_1^4 A_1\mathcal{F}_{12}$, which equals $\sigma T_1^4 A_2\mathcal{F}_{21}$. To find $\mathcal{F}_{21}$ use Fig. 4.3.3, line 5, from which $F_{21} = 0.81$. Then from Eq. (4.3.20).

$$\mathcal{F}_{21} = 1/[(1/0.81) + (1/1 - 1) + (2.4/\pi)(1/0.8 - 1) = 0.702$$

This amounts to saying that the system of refractory-backed tubes is equal in radiating power to a continuous plane A_2 replacing the tubes and refractory back of them, having a temperature equal to that of the tubes and an equivalent or effective emissivity of 0.702.

The new simplified furnace now consists of an enclosure formed by two 6×10 ft radiating side walls (area A_2, of emissivity 0.702), a 5×10 ft receiving plane on the floor (A_3), and refractory surfaces (A_R) to complete the enclosure (ends, roof, and floor side strips); the desired heat transfer is

$$q_{2=3} = \sigma(T_1^4 - T_3^4)A_2\mathcal{F}_{23}$$

To evaluate $\mathcal{F}_{23}$, start with the direct interchange factor F_{23}. $F_{23} = F$ from A_2 to (A_3 + a strip of A_R alongside A_3 which has a common edge with A_2) minus F from

A_2 to the strip only. These two F's may be evaluated from case 3 for direct-view factors. For the first F, $Y/X = 6/10$, $Z/X = 6.5/10$, $F = 0.239$; for the second F, $Y/X = 6/10$, $Z/X = 1.5/10$, $F = 0.100$. Then $F_{23} = 0.239 - 0.10 = 0.139$. Now $\overline{F}$ may be evaluated. From Eq. (4.3.21) et seq.,

$$A_2\overline{F}_{23} = \overline{23} + \frac{1}{1/\overline{2r} + 1/\overline{3r}}$$

$$\overline{F}_{23} = F_{23} + \frac{1}{1/F_{2r} + (A_2/A_3)(1/F_{3r})}$$

Since A_2 "sees" A_r, A_3, and some of itself (the plane opposite), $F_{2r} = 1 - F_{22} - F_{23}$. F_{22}, the direct interchange factor between parallel 6×10 ft rectangles separated by 8 ft, may be taken as the geometric mean of the factors for 6-ft squares separated by 8 ft, and 10-ft squares separated by 8 ft. These come from Fig. 4.3.2, line 2, according to which $F_{22} = \sqrt{0.13 \times 0.255} = 0.182$. Alternatively, the first of the 10 cases listed above under "Direct-View Factors" may be used. Then $F_{2r} = 1 - 0.182 - 0.139 = 0.679$. The other required direct factor is $F_{3r} = 1 - F_{32} = 1 - F_{23}A_2/A_3 = 1 - 0.139 \times {}^{120}\!/_{50} = 0.666$. Then $\overline{F}_{23} = 0.139 + \{1/[(1/0.679) + (120/50)(1/0.666)]\} = 0.336$. Having $\overline{F}_{23}$, we may now evaluate the factor $\mathcal{F}_{23}$ using Eq. (4.3.20) with $A_1 \to A_2$, $A_2 \to A_3$, and $[\overline{S_1S_2}]_{1B} \to A_2\overline{F}_{23}$.

$$\mathcal{F}_{23} = \frac{1}{1/0.336 + 1/0.702 - 1 + (120/50)(1/0.9 - 1)} = 0.273$$

$$\dot{Q}_{\text{net}} = \sigma(T_1^4 - T_3^4)A_2\mathcal{F}_{23} = 0.171(19.6^4 - 16.6^4)(120)(0.273) = 402{,}000 \text{ Btu/h}$$

In SI units

$$\dot{Q}_{\text{net}} = 5.67(10.89^4 - 9.22^4)(120 \times .3048^2)(0.273) = 118{,}000 \text{ W}$$

A result of interest is obtained by dividing the term $A_2\mathcal{F}_{23}(120 \times 0.273$, or 32.7 ft^2) by the actual area A_1 of the radiating tubes [$(\pi/2.4) \times 60 \times 2 = 157$ ft^2]. This is $32.7/157 = 0.208$; i.e., the net radiation from a tube to the stock is 20.8 percent as much as if the tube were black and completely surrounded by black stock.

Enclosures of Surfaces That Are Not Diffuse Reflectors The total interchange-area concept has been generalized to include surfaces the reflectance ρ of which can be divided into a diffuse, or Lambert-reflecting, component ρ_D and a specular component ρ_S independent of angle of incidence, with $\varepsilon + \rho_S + \rho_D = 1$. In application to concentric spheres or infinite cylinders, with A_1 the inner surface, the method yields (Hottel and Sarofim, p. 181)

$$A_1\mathcal{F}_{12} \equiv \overline{S_1S_2} = \frac{1}{\dfrac{1}{A_1\varepsilon_1} + \dfrac{1}{A_2}\left(\dfrac{1}{\varepsilon_2} - 1\right) + \dfrac{\rho_{s2}}{1 - \rho_{s2}}\left(\dfrac{1}{A_1} - \dfrac{1}{A_2}\right)} \tag{4.3.23}$$

When there is no specular reflectance, the third term in the denominator drops out, in agreement with Eq. (4.3.18). When the reflectance is exclusively specular, the denominator becomes $1/(A_1\varepsilon_1) + \rho_{S2}/[A_1(1 - \rho_{S2})]$, easily derivable from first principles.

RADIATION FROM FLAMES, COMBUSTION PRODUCTS, AND PARTICLE CLOUDS

The radiation from a flame consists of (1) radiation throughout the spectrum from burning soot particles of microscopic and submicroscopic dimensions, from suspended larger particles of coal, coke, or ash, all contributing to what is spoken of as flame luminosity, (2) infrared radiation, mostly from the water vapor and carbon dioxide in the hot gaseous combustion products, and (3) nonequilibrium radiation associated with the combustion process itself, called chemiluminescence and not a significant contributor to the total radiation. A major problem is the effect of the shape of the emitting volume on the radiative flux; this will be considered first.

Mean Beam Lengths Evaluation of radiation from a nonisothermal volume is beyond the scope of this section (see Hottel and Sarofim, Chap. 11). If a volume emitter is isothermal and at a temperature T, the ratio of the emission from an element of its volume subtending the solid angle $d\Omega$ at a receiver element dA, and making the angle θ with the normal thereto, to blackbody radiation arriving from within the same solid angle is called the **gas emissivity.** Clearly, ε depends on the path length L through the volume to dA. A hemispherical volume radiating to a spot on the center of its base represents the case in which L is independent of direction. Flux at that spot relative to hemispherical blackbody flux is thus an alternative way to visualize emissivity. The flux density to an area of interest on the envelope of an emitter volume of any shape can be matched by that at the base of a hemispherical volume of some radius L, which will be called the **mean beam length.** It is found that, although the ratio of L to a characteristic dimension D of the shape varies with opacity, the variation is small enough for most engineering purposes to permit use of a constant ratio, L_M/D, where L_M is the **average mean beam length.** L_M can be defined to apply either to a spot on the envelope or to any finite portion of its area. An important limiting case is that of opacity approaching zero ($pD \to 0$, where p = partial pressure of the emitter constituent). For this case, L (called L_0) equals $4 \times$ ratio of gas volume to bounding area when interest is in radiation to the entire envelope. For the range of pD encountered in practice, L (now L_M) is always less. For various shapes, 0.8 to 0.95 times L_0 has been found optimum (see Table 4.3.3); for shapes not reported in Table 4.3.3, a factor of 0.88 (or $L_M = 0.88L_0 = 3.5V/A$) is recommended.

Luminous Flames Luminosity conventionally refers to soot radiation. Soot is formed in locally fuel-rich portions of flames in amounts that usually correspond, at atmospheric pressure, to amounts less than 1 percent of the carbon in the fuel. Because soot particles are small relative to the wavelength of the radiation of interest in flames (soot primary particle diameters on the order of 20 nm compared to wavelengths of interest of 500 to 8000 nm), the incident radiation permeates the particles and the absorption is proportional to the volume of the particles. In the limit of $r/\lambda \ll 1$, the so-called *Rayleigh limit,* the monochromatic emissivity ε_λ is given by

$$\varepsilon_\lambda = 1 - e^{-Kf_vL/\lambda} \tag{4.3.24}$$

where f_v is the volume of soot per unit volume of space, L is the path length in the same units as λ, and K is dimensionless. The value K will vary with fuel type, experimental conditions, and the temperature history of the soot. The values from a wide range of systems are within a factor of about 2 of one another. The single most important factor governing the value of K is the hydrogen/carbon ratio of the soot with the value of K increasing as the H/C ratio decreases. A value of 9.9 is recommended on the basis of seven studies involving 29 fuels (Mulholland and Croarkin, *Fire and Materials* **24,** 2000, pp. 227–230).

The total emissivity of soot ε_s can be shown to be

$$\varepsilon_s = \int_0^1 \varepsilon_\lambda\, df(\lambda T) = 1 - \frac{15}{4}\left[\Psi^{(3)}\left(1 + \frac{Kf_vLT}{c_2}\right)\right] \tag{4.3.25}$$

where $\Psi^{(3)}(x)$ is the pentagamma function of x. An excellent approximation to Eq. (4.3.25) is

$$\varepsilon_s \cong 1 - \left(1 + \frac{Kf_vLT}{c_2}\right)^{-4} \tag{4.3.26}$$

Expression of ε_s in an e power for combination with the gas emissivity correlation is feasible. In that form

$$\varepsilon_s = 1 - e^{-3.83\,Kf_vLT/c_2} \tag{4.3.27}$$

The approximate relation is good to better than 5 percent for arguments giving values of ε_s less than 0.5.

The biggest uncertainty at present in estimating soot emissivities lies in the estimation of the soot volume fraction f_v. Soot forms in the fuel-rich zones of flames. Soot formation rates are a function of fuel type, mixing rate, local equivalence ratio, temperature, and pressure. Soot formation increases with the aromaticity or C/H ratio of fuels with benzene, α-methyl naphthalene, and acetylene having a high propensity to form soot and methane having a low soot formation propensity; oxygenated fuels, such as alcohols, emit little soot. In practical turbulent diffusion flames, soot forms on the fuel side of the flame front; in premixed flames, at a given temperature, the rate of soot formation increases rapidly as the equivalence ratio exceeds 2.0. Soot burns out rapidly,

Table 4.3.3 Mean Beam Lengths for Volume Radiation

Shape	Characteristic dimension D	L_0/D	L_M/D
Sphere	Diameter	0.67	0.63
Infinite cylinder	Diameter	1	0.94
Semi-infinite cylinder, radiating to:

1 × 6 face	Shortest edge	1.24	
1 × 2 face	Shortest edge	1.18	
Whole surface	Shortest edge	1.2	
Infinite parallel planes	Clearance	2.00	1.76
Space outside infinite bank of tubes, centers on equilateral triangles; tube diam = clearance	Clearance	3.4	2.8
Same, except tube diam = 0.5 clearance	Clearance	4.45	3.8
Same, except tube centers on squares, diam = clearance	Clearance	4.1	3.5

in less than 0.1s, under fuel-lean conditions (equivalence ratios less than 1) at temperature above 1,500 K. Because of this rapid soot burnout, soot is usually localized in a relatively small fraction of a furnace or combustor volume. Long, poorly mixed diffusion flames promote soot formation while highly backmixed combustors can burn soot-free. The peak volumetric soot concentration f_v in a typical atmospheric pressure flame is of the range of 1×10^{-7} to 1×10^{-6}, corresponding to a conversion to soot of about 1.5 to 15 percent of the carbon in the fuel. (In calculating f_v at high pressures, allowance needs to be made for the significant increase with pressure of soot formation and for the inverse proportionality of f_v and pressure.) Great progress has been made in the ability to calculate soot in premixed flames [see, for examples, the comparisons of predictions of soot concentration in a well-stirred reactor operated over a wide range of equivalent ratios and temperatures in Brown, Revzan, and Frenklach, *Twenty-seventh Symposium (International) on Combustion*, 1998, pp. 1573–1580] and in a turbulent diffusion flame (Zucca, Marchisio, Barresi, and Fox, "Chemical Engineering Science," 2005).

The importance of soot radiation varies widely between combustors: In large boilers the soot is confined to a small volume and is of only local importance; in gas turbines minimizing the heat flux to the combustor lining is of paramount importance so that only small incremental soot radiation is of concern; in high-temperature glass tanks, the added 0.1 to 0.2 due to soot emissivity is valued in oil-fired flames, and efforts, mostly unsuccessful, had been made to augment the emissivity of natural gas–fired flames; soot contributions to the radiation of pool fires are often dominant and impact the safe separation distances from dikes around oil tanks and the distance from a rig where a flare is located.

Clouds of Large Black Particles The emissivity of a cloud of particles depends on their area projected along the line of sight. The projected area per unit volume of space is the projected area A of a particle times the particle number concentration c, or the volume fraction f_v of space occupied by particles times b/d, the projected-surface/volume ratio, where d is the characteristic dimension. [For any randomly oriented particles without dimples, A/(total area) is ¼; for spheres, $b = 3/2$.] The emissivity of a particle cloud is then given by the alternative formulations

$$\varepsilon = 1 - e^{-bf_vL/d} = 1 - e^{-cAL} \tag{4.3.28}$$

As an example, consider heavy fuel oil ($CH_{1.5}$, s.g. 0.95) atomized to a surface mean particle diameter of d μm, burned with 20 percent excess air to produce coke residue particles having the original drop diameter, and suspended in combustion products at 1,500 K. From stoichiometry, $f_v = 1.27 \times 10^{-5}$. For spherical particles $b = 3/2$, and the flame emissivity due to the particles along a path L will be $1 - e^{-1.9 \times 10 - 2L/d}$. With 200-$\mu$m particles and an L of 3 m, the particle contribution to emissivity will be 0.25. Soot luminosity will increase this; particle burnout will decrease it. The combined emissivity due to several kinds of emitters will be treated later. The correction for nonblackness of the particles is complicated by multiple scatter of the radiation reflected by each particle. The emissivity ε_M of a cloud of gray particles of individual surface emissivity ε_1 can be estimated by the use of Eq. (4.3.28) with its exponent multiplied by ε_1 if the optical thickness cAL does not exceed about 2.

Gaseous Combustion Products Radiation from water vapor and carbon dioxide occurs in spectral bands in the infrared. Its magnitude is 3 to 10 times that of convection at furnace temperatures. It depends on gas temperature T_G, on the partial pressure-beam length products p_wL and p_cL (subscripts w and c refer to water vapor and carbon dioxide), and to a much lesser extent on total and partial pressure. The gas emissivity ε_G is the sum of the separate contributions due to H_2O and CO_2, corrected for pressure broadening of the spectral bands and for band overlap (Hottel and Sarofim, Chap. 6). The elaborate calculations can

be combined for a restricted set of conditions, here taken to be the practically important cases of 1-atm total pressure and partial pressures representative of fossil fuel combustion in air. In the range of furnace operating conditions the product $\overline{\varepsilon_G T_G}$ varies much less than ε_G with T_G, and $\overline{\varepsilon_G T_G}$ depends primarily on $(p_w + p_c)L$, much less on $p_w/(p_w + p_c)$, and so little on T_G as to permit linear interpolation between widely separated T_G's. An equation of the form

$$\log \overline{\varepsilon_G T_G} = a_0 + a_1 \log pL + a_2 \log^2 pL + a_3 \log^3 pL \qquad (4.3.29)$$

where p is the sum of partial pressures $p_w + p_c$ atm and L is the mean beam length, has been found capable of fitting emissivity data over a 1000-fold range of pL, from 0.01 to 10 m · atm (0.03 to 30 ft · atm).

Table 4.3.4, section 2, gives values of the constants representing the results of an averaging of all the available total and integrated spectral data on CO_2 and H_2O, together with corrections for spectral band broadening and overlap. Equation (4.3.29) represents the original data with a precision greater than their accuracy. The constants are given for computation in either metres and kelvins or feet and degrees Rankine for mixtures, in nonradiating gases, of water vapor alone, CO_2 alone, and four p_w/p_c mixtures. Four suffice, since a change halfway from one mixture ratio to the adjacent one changes the emissivity by a maximum of only 5 percent; linear interpolation may be used if necessary. The constants are given for only three temperatures, which is adequate for linear interpolation since $\overline{\varepsilon_G T}$ changes a maximum of only one-sixth due to a change from one temperature base halfway to the adjacent one. Based on metre atmospheres and kelvins, the interpolation relation, with T_H and T_L representing the higher and lower base temperatures bracketing T, and with the brackets in the term $[A(x)]$ indicating that the parentheses refer not to a multiplier but to an argument, is

$$\overline{\varepsilon_G T_G} = \frac{[\overline{\varepsilon_G T_H}(pL)](T_G - T_L) + [\overline{\varepsilon_G T_L}(pL)](T_H - T_G)}{500} \qquad (4.3.30)$$

Extrapolation to a temperature which is above the highest or below the lowest of the three base temperatures in Table 4.3.4 uses the same

NOTE: Values of $p_w/(p_w + p_c)$ of ⅓, ½, ⅔, ¾ may be used to cover the ranges 0.2–0.42, 0.42–0.6, 0.6–0.7, and 0.7–0.8, respectively, with a maximum error in ε_G of 5 percent at $pL = 6.5$ m · atm, less at lower pL's. Linear interpolation reduces the error generally to less than 1 percent. Linear interpolation or extrapolation on T introduces an error generally below 2 percent, less than the accuracy of the original data.

formulation, but one of the terms becomes negative. Linearization on the constants a_0 to a_3 rather than on $\overline{\varepsilon_G T}$ may be preferable if fuel quality is unchanging.

When pL lies in the 25-fold range of 0.046 to 1.15 m · atm (0.15 to 3.75 ft · atm), adequate for furnaces, a much simpler two-constant relation is adequate.

$$\overline{\varepsilon_G T} = \begin{cases} b(pL - 0.015)^n & \text{with } T = \text{K}, pL = \text{m} \cdot \text{atm} \\ b(pL - 0.05)^n & \text{with } T = {}^\circ\text{R}, pL = \text{ft} \cdot \text{atm} \end{cases}$$

The constants are given in Table 4.3.4, section 1.

Combined Radiation from Gases and Suspended Solids

The total emissivity of gases and suspended solids is less than the sum of the separate contributions because of interference between overlapping spectral emissions. The spectral overlap of H_2O and CO_2 radiation has been taken into account by the constants of Table 4.3.4 used for obtaining ε_G. Additional overlap occurs when soot emissivity ε_s is added. If the emission bands of water vapor and CO_2 were randomly placed in the spectrum and soot radiation were gray, the combined emissivity would be $\varepsilon_G + \varepsilon_s$ minus an overlap correction $\varepsilon_G\varepsilon_s$. Monochromatic soot emissivity is higher as the wavelength gets shorter, and in a highly sooted flame at 1,500 K half the soot emission lies below 2.5 μm where H_2O and CO_2 emission is negligible. Then the correction $\varepsilon_G\varepsilon_s$ must be reduced, and the following is recommended:

$$\varepsilon_{G+s} = \varepsilon_G + \varepsilon_s - M\varepsilon_G\varepsilon_s \tag{4.3.31}$$

where M depends mostly on T_G and to a much less extent on the optical density Kf_vL. Values that have been calculated from this simple model can be represented with acceptable error by

$$M = 1.07 + 2.7 \times 10^5 f_v L - 0.27(T/1{,}000) \qquad (0 < M < 1)$$

If, in addition to gas and soot, massive particles such as fly ash, coal char, or carbonaceous cenospheres from heavy fuel oil of emissivity ε_M are present, it is recommended that the total emissivity be approximated by

$$\varepsilon_{\text{total}} = \varepsilon_{G+s} + \varepsilon_M - \varepsilon_{G+s}\varepsilon_M \tag{4.3.32}$$

Radiant interchange between a gas and a *completely bounding black surface* at T_1 produces a surface flux density q given by

$$q = \sigma(\varepsilon_G T_G^4 - \alpha_{G1} T_1^4) \tag{4.3.33}$$

where α_{G1} is the **absorptivity** of the gas at T_G for radiation from a surface at T_1. The absorptivity of water vapor–CO_2 mixtures may also be obtained from the constants for emissivities. The product $\overline{\alpha_{G1}T_1}$—the absorptivity of gas at T_G for black radiation at T_1 times the surface temperature—is the product $\overline{\varepsilon_G T_1}$ with ε_G evaluated at surface temperature T_1 instead of T_G and at pLT_1/T_G instead of pL, then multiplied by $(T_G/T_1)^{0.5}$, or

$$\overline{\alpha_{G1}T_1} = [\overline{\varepsilon_G T_1}(pLT_1/T_G)](T_G/T_1)^{0.5} \tag{4.3.34}$$

The exponent 0.5 is an adequate average of the exponents for the pure components. The interpolation relation for absorptivity is

$$\overline{\alpha_{G1}T_1} = \left[\overline{\varepsilon_G T_H}\left(\frac{pLT_H}{T_G}\right)\right]\left(\frac{T_G}{T_H}\right)^{0.5}\frac{T_1 - T_L}{500} + \left[\overline{\varepsilon_G T_L}\left(\frac{pLT_L}{T_G}\right)\right]\left(\frac{T_G}{T_L}\right)^{0.5}\frac{T_H - T_1}{500} \tag{4.3.35}$$

The base temperature pair T_H and T_L can be different for the evaluation of ε_G and α_{G1} if T_G and T_1 are far enough apart. Extrapolation from the lowest T_G in Eq. (4.3.35) to a much lower T_1 to obtain α_{G1} may yield too high a value for it. That occurs, however, only when $T_1 \ll T_G$, and the fourth-power temperature relation makes the error in q negligible.

If the surface is not black, the right-hand side of Eq. (4.3.33) must be modified. If the surface is gray, multiplication by $\alpha_1(\equiv \varepsilon_1)$ allows for reduction in the primary beam from gas to surface and surface to gas, but some of the gas radiation initially reflected from the surface has further opportunity for absorption at the surface because the gas is but incompletely opaque to the reflected beam. Consequently, the factor to allow for surface grayness lies between absorptance α_1 and unity, nearer the latter the more transparent the gas (low pL) and the more convoluted the surface. In the absorptance range of most industrial surfaces, 0.7 to 1.0, an adequate approximation consists in use of an effective absorptance α_1' halfway between the actual value and unity. If the surface is not gray, q depends much more on surface absorptance, which modifies $\varepsilon_G T_G^4$, than on emittance, which modifies $\alpha_{G1}T_1^4$. Absorption is treated more rigorously later in the section.

EXAMPLE. Flue gas containing 9.5 percent CO_2 and 7.1 percent H_2O, wet basis, flows through a bank of tubes of 1.5-in OD on equilateral triangular centers 4.5 in apart. In a section in which the gas and tube surface temperatures are 1,700 and 1,000°F, what is the heat transfer rate per square foot of tube area, due to gas radiation only? Tube surface absorptance = 0.8.

T_G = 2,160°R (1,200 K); T_S = 1,460°R (811 K)

$p_w/(p_w + p_c)$ = 7.1/16.6 = 0.428; use 0.5

pL = 0.166 [3.8(4.5 − 1.5)/12] = 0.158 ft · atm (0.0480 m · atm)

$pL(Ts/T_G)$ = 0.1580(1,460/2,160) = 0.1066 ft · atm (0.0325 m · atm)

From Table 4.3.4, for T_G = 1,500 K and pL = 0.0480 and 0.0325, εT = 125 and 101 K, and for T_G = 1,000 K and pL = 0.0480 and 0.0325, εT = 129 and 107 K. Then

$$\varepsilon_G = \frac{1}{1{,}200}\frac{125(1{,}200 - 1{,}000) + 129(1{,}500 - 1{,}200)}{1{,}500 - 1{,}000} = 0.106$$

$$\alpha_{G1} = \frac{1}{811}\frac{101(811 - 1{,}000) + 107(1{,}500 - 811)}{1{,}500 - 1{,}000} = 0.135$$

The effective surface absorptance factor α_1 = (0.8 + 1)/2 = 0.9. From Eq. (4.3.33), modified,

$$q = 0.9 \times 0.1713(0.106 \times 21.6^4 - 0.135 \times 14.6^4) = 2{,}612 \text{ Btu/(ft}^2 \cdot \text{h)}$$

or

$$q = 0.9 \times 5.67(0.106 \times 12^4 - 0.135 \times 8.111^4) = 8{,}235 \text{ W/m}^2$$

This is equivalent to a convection coefficient of 2,612/700 or 3.73 Btu/(ft² · F · h) or 21.2 W/(m² · K). The emissivity of an equivalent gray flame is $(0.106 \times 21.6^4 - 0.135 \times 14.6^4)/(21.6^4 - 14.6^4) = 0.098$.

RADIATIVE EXCHANGE IN ENCLOSURES OF RADIATING GAS

The so-called *radiant section* of a furnace presents a heat-transfer problem in which there enters the combined action of direct radiation from the flame to the stock or heat sink and radiation from the flame to refractory surfaces and thence back through the flame (with partial absorption) to the sink, convection, and external losses. Solutions of the problem based on varying degrees of simplification are available, including allowance for temperature variation in both gas and refractory walls (Hottel and Sarofim, Chap. 14). A less rigorous treatment suffices, however, for handling many problems. There are two limiting cases: the long chamber with gas temperature varying only in the direction of gas flow and the compact chamber containing a gas or flame at a uniform temperature. The latter, with variations, will be considered first.

Total Exchange Areas $\overline{SS}$ and $\overline{GS}$ The arguments leading to the development of the interchange factor $A_i\mathcal{F}_{ij}(=\overline{S_iS_j})$ between surface zones [Eq. (4.3.14) et seq.] apply to the case of absorption within the gas volume if, in the evaluation of the direct exchange area, allowance is made for attenuation of the radiant beam through the gas. This necessitates nothing more than the redefinition, in Eqs. (4.3.7) to (4.3.22), of every term $\overline{ij}(\equiv s_is_j \equiv A_iF_{ij})$ to represent, per unit of black emissive power, flux from A_i through an absorbing gas to A_j; that is, the prior F_{ij} must be multiplied by a mean transmittance τ_{ij} of the gas ($= 1 - \alpha_{ij} = 1 - \varepsilon_G$ for a gray gas). In a system containing an isothermal gas and source-sink boundaries of areas $A_1, A_2, \ldots, A_n$, the total emission from A_1 per unit of its black emissive power is $A_1\varepsilon_1$, of which $\overline{S_1S_1} + \overline{S_1S_2} + \cdots + \overline{S_1S_n}$ is absorbed in the surfaces by all mechanisms, direct and indirect. The difference has been absorbed in the gas; it is called the **gas surface total exchange area** $\overline{GS_1}$:

$$\overline{GS_1} = A_1\varepsilon_1 - \sum_i \overline{S_1S_i} \tag{4.3.36}$$

The letters identifying total exchange areas are, of course, commutative; $\overline{GS}_1 \cong \overline{S_1G}$. Note that although $\overline{S_1S_1}$ is never used in calculating radiative interchange, its value is needed for use of Eq. (4.3.36) in calculating $\overline{GS}_1$. $\overline{GS}_1$ embraces the full effect of radiation complexities on radiative exchange between gas and A_1, including multiple reflection at all surfaces, and it is capable of including the effects of gas nongrayness and of assistance given by refractory surfaces to gas-A_1 interchange. It is but mildly temperature-sensitive and is independent of any changes in conduction, convection, mass flow, and energy balances except for their effect on the temperature used in evaluating it.

If the gas volume is not isothermal, the principles used here can be extended to setting up balances on a zoned gas volume (see, e.g., Hottel and Sarofim, "Radiative Transfer," McGraw-Hill, Chap. 11).

Systems with a Single Gas Zone and Two Surface Zones

An enclosure consisting of but one isothermal gas zone and two gray surface zones, when properly specified, can model so many industrially important radiation problems as to merit detailed presentation. One can evaluate the total radiation flux between any two of the three zones, including multiple reflection at all surfaces.

$$\begin{aligned} \dot{Q}_{G\leftrightarrow 1} &= \overline{GS}_1\sigma(T_G^4 - T_1^4) \\ \dot{Q}_{1\leftrightarrow 2} &= \overline{S_1S_2}\sigma(T_1^4 - T_2^4) \end{aligned} \tag{4.3.37}$$

The total exchange area takes a relatively simple closed form, even when important allowance is made for gas radiation not being gray and when a reduction of the number of system parameters is introduced by assuming that one of the surface zones, if refractory, is radiatively adiabatic (see later). Before allowance is made for these factors, the case of a **gray gas** enclosed by two source-sink surface zones will be presented. Modification of Eqs. (4.3.7) to (4.3.22), discussed previously, combined with the assumption that a single mean beam length applies to all transfers, i.e., that there is but one gas transmittance τ $(= 1 - \varepsilon_G)$, gives

$$\overline{S_1S_2} = \frac{A_1\varepsilon_1\varepsilon_2F_{12}}{1/\tau + \tau\rho_1\rho_2(1 - F_{12}/C_2) - \rho_1(1 - F_{12}) - \rho_2(1 - F_{21})} \tag{4.3.38}$$

$$\overline{S_1S_1} = \frac{A_1\varepsilon_1^2[F_{11} + \rho_2\tau(F_{12}/C_2 - 1)]}{\text{same denominator}} \tag{4.3.39}$$

$$\overline{GS_1} = \frac{A_1\varepsilon_1\varepsilon_G[1/\tau + \rho_2(F_{12}/C_2 - 1)]}{\text{same denominator}} \tag{4.3.40}$$

(Here C is the area expressed as a ratio to the total enclosure area A_T; $C_1 = A_1/A_T$, $C_2 = A_2/A_T$; $C_1 + C_2 = 1$.) The three equations above suffice to formulate total exchange areas for gas-enclosing arrangements which include, e.g., the four geometric cases illustrated in Table 4.3.5, to be discussed later.

An additional surface arrangement of importance is a single zone surface fully enclosing gas. With the gas assumed gray, the simplest derivation of $\overline{GS}_1$ is to note that the emission from surface A_1 per unit of its blackbody emissive power is $A_1\varepsilon_1$, of which the fractions ε_G and $(1 - \varepsilon_G)\varepsilon_1$ are absorbed by the gas and the surface, respectively, and the surface reflected residue always repeats this distribution. Therefore,

$$\overline{GS}_{\substack{\text{single surface}\\ \text{zone surrounding}\\ \text{gray gas}}} \equiv \overline{GS}_1 = A_1\varepsilon_1\frac{\varepsilon_G}{\varepsilon_G + (1 - \varepsilon_G)\varepsilon_1} = \frac{A_1}{1/\varepsilon_G + 1/\varepsilon_1 - 1} \tag{4.3.41}$$

Alternatively, $\overline{GS}_1$ could be obtained from case 1 of Table 4.3.5 by letting plane area A_1 approach 0, leaving A_2 as the sole surface zone.

Although departure of gas from grayness has a marked effect on radiative transfer, the subject is complex and will be presented in stages, as the cases shown in Table 4.3.5 are discussed.

Partial Allowance for the Effect of Gas Nongrayness on Total Exchange Areas

A radiating gas departs from grayness in two ways: (1) Gas emissivity ε_G and absorptivity α_{G1} are not the same unless T_1 equals T_G. (2) The fractional transmittance τ of radiation through successive path lengths L_m due to surface reflection, instead of being constant, keeps increasing because at the wavelengths of high absorption the incremental absorption decreases with increasing path length. The first of these effects is sufficiently straightforward to be introduced at this point, coupled with allowance for refractory surfaces being substantially radiatively adiabatic. The second, much more complicated effect will be introduced later; it sometimes changes the computed flux significantly.

In the simplest case of gas-surface radiative exchange—a gas at T_G completely enclosed by a black surface at T_1—the net flux $\dot{Q}_{G\leftrightarrow 1}$ is given by

$$\dot{Q}_{G\leftrightarrow 1} = \sigma(\varepsilon_G T_G^4 - \alpha_{G1}T_1^4) \equiv \sigma\varepsilon_{G,e}(T_G^4 - T_1^4)$$

The evaluation of the absorptivity α_G was covered in Eqs. (4.3.34) and (4.3.35). The second form of the above equation defines $\varepsilon_{G,e}$, the equivalent gray-gas emissivity

$$\varepsilon_{G,e} = \frac{\varepsilon_G - \alpha_{G1}(T_1^4/T_G^4)}{1 - (T_1/T_G)^4} \tag{4.3.42}$$

Although this introduction of $\varepsilon_{G,e}$ has added no information, the evaluation of $\dot{Q}_{G\leftrightarrow 1}$ in terms of $\varepsilon_{G,e}$ rather than ε_G and α_{G1} gives a better structure for trial-and-error solutions of problems in which either T_G or T_1 is not known and a second energy relation is available.

With partial allowance for gas nongrayness having been made, the evaluation of radiative flux $\dot{Q}_{G\leftrightarrow 1}$ or $\dot{Q}_{1\leftrightarrow 2}$ [Eq. (4.3.37)] for cases falling in one of the categories of Table 4.3.5 is straightforward if both A_1 and A_2 are source-sink surfaces. Wherever ε_G or τ appears in the table, or in Eqs. (4.3.38) to (4.3.41), use $\varepsilon_{G,e}$ or $1 - \varepsilon_{G,e}$ instead.

EXAMPLE (FIRST APPROXIMATION TO NONGRAYNESS). Methane is burned to completion with 20 percent excess air (air half saturated with water vapor at 289 K (60°F), 0.0088 mol H_2O/mol dry air) in a furnace chamber with floor dimensions of 3 × 10 m and 5 m high. The whole surface is a gray energy sink of emissivity 0.8 at 1,000 K, surrounding gas at 1,500 K, well stirred. Find the effective gas emissivity $\varepsilon_{G,e}$ and the surface radiative flux density, assuming that the only correction necessary for gas nongrayness is use of $\varepsilon_{G,e}$ rather than ε_G.

SOLUTION. Combustion is 1 CH_4 + 2 × 1.2 O_2 + 1.2 × (79/21)N_2 + 2 × 1.2 × 100/21 × 0.0088 H_2O going to 1 CO_2 + [2 + 2 × 1.2 × (100/21) × 0.0088] H_2O + 0.4 O_2 + 9.03 N_2 = 12.53 mol/mol of CH_4. And $P_C + P_W = (1 + 2.1)/12.53 = 0.2474$ atm. The mean beam length $L_m = 0.88 \times 4V/A_T = 0.88 \times 4(10 \times 3 \times 5)/\{2[2 \times (10 \times 3 + 10 \times 5 + 3 \times 5)]\} = 2.779$ m. And $pL_m = 0.2474 \times 2.779 = 0.6875$ m · atm. From emissivity Table 4.3.4, $b(1{,}500) = 540$; $n(1{,}500) = 0.42$; $b(1{,}000) = 444$; $n(1{,}000) = 0.34$. Also $\varepsilon_G(pL) = 540(0.6875 - 0.015)^{0.42}/1{,}500 = 0.3047$, and $\alpha_{G1}(\text{pL}) = 444(0.6875 \times 1{,}000/1{,}500 - 0.015)^{0.34}(1{,}500/1{,}000)^{0.5}/1{,}000 = 0.4124$. Then $\varepsilon_{G,e}(pL) = [0.3047 - 0.4124(1{,}000/1{,}500)^4]/[1 - (1{,}000/1{,}500)^4] = 0.2782$. From Eq. (4.3.41), with ε_G replaced by $\varepsilon_{G,e}$, $(\overline{GS}_1/A_1) = 1/(1/0.2782 + 1/0.8\text{-}1) = 0.2601$. Then $\dot{Q}_{G\leftrightarrow 1}/A_1 = 56.7 \times 0.260[(1{,}500/1{,}000)^4 - (1{,}000/1{,}000)^4] = 59.91$ kW/m^2[18,990 Btu/(ft^2 · h)].

Refractory Surfaces If one of the surfaces A_r of an enclosure of gas is refractory, an extra temperature T_{refr} and an extra heat transfer equation are needed to determine the fluxes *unless* A_r can be assumed to be radiatively adiabatic. Consider the facts that irradiation of A_r plus convection from gas to it must equal back radiation plus conduction through it if steady state exists, and irradiation is enormous compared to convection. It then follows that the difference between convection and conduction is so minute compared to irradiation or back radiation as to make A_r substantially radiatively adiabatic; assume that A_1 is a sourcesink zone and A_2 a radiatively adiabatic zone, and call it A_r. The condition for adiabaticity of A_r is

$$\overline{GS}_r(T_G^4 - T_r^4) = \overline{S_rS_1}(T_r^4 - T_1^4)$$

or, to eliminate T_r,

$$\frac{T_G^4 - T_r^4}{1/\overline{GS}_r} = \frac{T_r^4 - T_1^4}{1/\overline{S_rS_1}} = \frac{T_G^4 - T_1^4}{1/\overline{GS}_r + 1/\overline{S_rS_1}} \tag{4.3.43}$$

The net flux from gas G is $\overline{GS}_1\sigma(T_G^4 - T_1^4) + \overline{GS}_r\sigma(T_G^4 - T_r^4)$ which, with replacement of the last term, using Eq. (4.3.43), gives the single

Table 4.3.5 Total Exchange Areas for Four Arrangements of Two-Zone-Surface Enclosures of a Gray Gas*

Case 1	Case 2	Case 3	Case 4
			A plane surface A_1 and a surface A_2 complete the enclosure $F_{12} = 1$ $\frac{\overline{S_1S_2}}{A_1} = \frac{\varepsilon_1\varepsilon_2}{D_1}$ $\frac{\overline{GS_1}}{A_1} = \frac{\varepsilon_1\varepsilon_G(1/\tau + \rho_2 C_1/C_2)}{D_1}$ $\frac{\overline{GS_2}}{A_2} = \frac{\varepsilon_2\varepsilon_G(1/\tau + \rho_1 C_1/C_2)}{D_1}$ $\frac{\overline{S_1S_1}}{A_1} = \frac{\varepsilon_1^2\tau\rho_2 C_1/C_2}{D_1}$ $D_1 \equiv \frac{1}{\tau} - \rho_2\left[1 - \frac{C_1}{C_2}(1 - \tau\rho_1)\right]$ $\tau = 1 - \varepsilon_G$	Infinite parallel planes $F_{12} = F_{21} = 1$ $\frac{\overline{S_1S_2}}{A_1} = \frac{\varepsilon_1\varepsilon_2}{D_2}$ $\frac{\overline{GS_1}}{A_1} = \frac{\varepsilon_1\varepsilon_G(1/\tau + \rho_2)}{D_2}$ $\frac{\overline{S_1S_1}}{A_1} = \frac{\varepsilon_1^2\rho_2\tau}{D_2}$ $D_2 \equiv \frac{1}{\tau} - \tau\rho_1\rho_2$	Concentric spherical or infinite cylindrical surface zones, A_1 inside $F_{12} = 1 \quad F_{21} = \frac{A_1}{A_2} = \frac{C_1}{C_2}$ $\frac{\overline{S_1S_2}}{A_1} = \frac{\varepsilon_1\varepsilon_2}{D_3}$ $\frac{\overline{GS_1}}{A_1} = \frac{\varepsilon_1\varepsilon_G(1/\tau + \rho_2 C_1/C_2)}{D_3}$ $\frac{\overline{GS_2}}{A_2} = \frac{\varepsilon_2\varepsilon_G(1/\tau + \rho_1 C_1/C_2)}{D_3}$ $\frac{\overline{S_1S_1}}{A_1} = \frac{\varepsilon_1^2\rho_2\tau C_1/C_2}{D_3}$ $D_3 \equiv \frac{1}{\tau} - \rho_2\left[1 - \frac{C_1}{C_2}(1 - \tau\rho_1)\right]$	Two-surface-zone enclosure, each zone in one or more parts, any shape Assume that enclosing surface is a speckled enclosure, or spherical $F_{12} = F_{22} = C_2$ $F_{21} = F_{11} = C_1$ $\frac{\overline{S_1S_2}}{A_1} = \frac{\varepsilon_1\varepsilon_2 C_2}{D_4}$ $\frac{\overline{GS_1}}{A_1} = \frac{\varepsilon_1\varepsilon_G/\tau}{D_4}$ $\frac{\overline{S_1S_1}}{A_1} = \frac{\varepsilon_1^2 C_1}{D_4}$ $D_4 \equiv \frac{1}{\tau} - \rho_1 C_1 - \rho_2 C_2$

* All equations above come from Eqs. (4.3.38) to (4.3.40), with substitutions for view factor F given before equations.

term multiplying a fourth-power temperature difference:

$$\dot{Q}_{G\leftrightarrow 1} = \sigma(T_G^4 - T_1^4)\left[\overline{GS_1} + \frac{1}{1/\overline{GS_r} + 1/\overline{S_rS_1}}\right] \equiv (\overline{GS_1})_R\sigma(T_G^4 - T_1^4) \qquad (4.3.44)$$

The bracketed term is called $(\overline{GS_1})_R$, the total exchange area from G to A_1 with assistance from a refractory surface. Table 4.3.5 supplies the forms for the three total exchange area terms needed to formulate $(\overline{GS_1})_R$, with A_r substituted for A_2 and with ε_G or τ replaced by $\varepsilon_{G,e}$ or $1 - \varepsilon_{G,e}$.

A general expression for a gray gas enclosure of two surfaces, one of which is radiatively adiabatic, comes from Eq. (4.3.44), in which $(\overline{GS_1})_R$ becomes $\overline{GS_1}$ because $\overline{S_rS_1}$ and $\overline{GS_r}$ are zero, and then from Eq. (4.3.36), which becomes $\overline{GS_1}[=(\overline{GS_1})_R] = A_1\varepsilon_1 - \overline{S_1S_1}$. With $\overline{S_1S_1}$ coming from Eq. (4.3.39), one finally obtains

$$\frac{(\overline{GS_1})_R}{A_1} = \frac{1}{\rho_1/\varepsilon_1 + 1/\{\varepsilon_G[1 + 1/(C_1/C_2 + \varepsilon_G/\tau F_{1r})]\}} \qquad (4.3.45)$$

Note that since the first denominator term is zero when A_1 is black, the denominator of the second term is $(\overline{GS_1})_R/A_1$ for a black surface.

The above equation is perfectly general when the **gas is gray** and the two enclosing surfaces are a sink and a radiatively adiabatic surface. When A_1 is a plane (simulation of slab or billet heating furnaces and glass tanks), $(\overline{GS_1})_R/A_1$ is Eq. (4.3.45) with $F_{1r} = 1$. A different but completely equivalent form is

$$\left[\frac{(\overline{GS_1})_R}{A_1}\right]_{\substack{A_1 \text{ is}\\ \text{plane}}} = \frac{1}{1/\varepsilon_1 + (1/\varepsilon_G - 1)^2/[1/(C_1\varepsilon_G) - 1]} \qquad (4.3.46)$$

For most refinery **processing furnaces,** with sink and refractory assumed to form a **speckled** enclosure, $(\overline{GS_1})_R/A_1$ is Eq. (4.3.45) with $F_{1r} = C_r$. A better but completely equivalent form is

$$\left[\frac{(\overline{GS_1})_R}{A_1}\right]_{\substack{\text{surface is}\\ \text{speckled}}} = \frac{1}{1/\varepsilon_1 + C_1(1/\varepsilon_G - 1)} \qquad (4.3.47)$$

As previously stated, partial allowance for the gas not being gray is made by evaluating $\overline{GS}$ or $(\overline{GS})_R$ with use of $\varepsilon_{G,e}$ rather than ε_G, and $1 - \varepsilon_{G,e}$ rather than τ, in Eqs. (4.3.45) to (4.3.47). A slightly better but more tedious allowance for partial **nongrayness** in evaluating $\dot{Q}_{\text{rad}}$ is to replace $\overline{GS_1}\sigma(T_G^4 - T_1^4)$, with $\overline{GS_1}$ evaluated by using $\varepsilon_{G,e}$, by $\overrightarrow{GS_1}T_G^4 - \overleftarrow{GS_1}T_1^4$, where $\overrightarrow{GS}$, and $\overleftarrow{GS}$, are evaluated by using ε_G and $\alpha_{G,1}$, respectively.

This completes the presentation of procedures for evaluating the total exchange area between gas and sink surface when the gas is gray or by making approximate allowance for the nongrayness by using ε_G and $\alpha_{G,1}$. These exchange areas can be used in the formulations below on furnace chamber performance. Methods will be presented first for a more rigorous treatment of gas nongrayness.

Full Allowance for Gas Nongrayness The above paragraphs failed to allow for the previously discussed change in gas transmittance on successive passages of reflected radiation through the gas. In many radiative transfer problems, interchange between many different pairs of radiators creates a system of simultaneous equations to be solved for the energy fluxes, and a shift from use of the Stefan-Boltzmann to the Planck equation would enormously increase the difficulty of solution. Use will be made of the fact that the total emissivity of a real gas, the spectral emissivity and absorptivity ε_λ of which vary in any way with λ, can be expressed *rigorously* as the a-weighted mean of a suitable number, n, of gray gas emissivity or absorptivity terms $\varepsilon_{G,i}$ or $\alpha_{G,i}$ representing the gray gas emissivity or absorptivity in the energy fractions a_i of the blackbody spectrum. Then

$$\varepsilon_G = \sum_0^n a_i\varepsilon_{G,i} = \sum_0^n a_i(1 - e^{-kpL}) \qquad (4.3.48)$$

The linearity between flux $\dot{Q}$ and blackbody emissive power E_B allows the above relations to be used for converting $\overline{GS}$ or $\overline{SS}$ for a gray gas to a form allowing for nongrayness. For a real gas $\overline{GS}$ or $\overline{SS}$ is the a_i-weighted sum of its values based on each of the $\varepsilon_{G,i}$ values of Eq. (4.3.48). Into an expression for $\overline{GS}_{\text{gray}}$ replace ε_G by $\varepsilon_{G,i}$, or τ by $1 - \varepsilon_{G,i}$, multiply the result by a_i and sum the resultant $\overline{GS}$ values to obtain $\overline{GS}_{\text{real gas}}$. Obviously, the number of terms n should be as small as possible while consistent with small error. Consider an n of 2, with the gas modeled as the sum of one gray gas plus a clear gas, with the gray gas of absorption coefficient k occupying the energy fraction a of the blackbody spectrum and the clear gas ($k = 0$) the fraction $1 - a$. Then, at path lengths L and $2L$,

$$\begin{aligned}[\varepsilon_G(pL)] &= a(1 - e^{-kpL}) + (1 - a)(0)\\ [\varepsilon_G(2pL)] &= a(1 - e^{-2kpL}) + (1 - a)(0)\end{aligned} \qquad (4.3.49)$$

Solution of these gives

$$\begin{aligned}a &= \frac{\varepsilon_G(pL)}{2 - \varepsilon_G(2pL)/\varepsilon_G(pL)}\\ kpL &= -\ln\left[1 - \frac{\varepsilon_G(pL)}{a}\right]\end{aligned} \qquad (4.3.50)$$

The equivalent gray gas emissivity in the spectral range a is $1 - e^{-kpL}$, from Eq. (4.3.48), and from Eq. (4.3.49) that is $\varepsilon_G(pL)/a$; in the spectral range $1 - a$, the equivalent gray gas emissivity is zero. This simple model will be correct for the contribution of the direct gas emission from path length L and for that of the once-reflected emission (path length $2L$); and the added contributions due to increasing numbers of reflections will be attenuated sufficiently by surface reflections to make errors in them unimportant. Note that a and k are not general constants; they are specific to the **subject mean beam length** L_m and come from basic data, such as Table 4.3.4. Note also that when full allowance for nongrayness is to be made by replacing ε_G by $\varepsilon_{G,e}$, then a is also changed to a_e, which comes from Eq. (4.3.50), with $\varepsilon_{G,e}$ replacing ε_G.

Conversion of gray gas total exchange areas $\overline{GS}$ and $\overline{SS}$ to their nongray forms is carried out as follows when the nongray model is gray-plus-clear gas: From Eq. (4.3.49) the equivalent gray gas emissivity in the spectral energy fraction a_e is $\varepsilon_{G,e}(pL)/a_e$, which replaces ε_G wherever it or its complement τ occurs in $\overline{GS}$; the result is then multiplied by a_e. There is no contribution from the clear gas energy fraction. Conversion of $\overline{SS}$ from gray to gray plus clear involves making the same substitution, but for $\overline{SS}$ another term must be added. For the clear gas contribution, 0 and 1 are substituted for ε_G and τ, and the result is multiplied by the weighting factor $1 - a_e$; this $\overline{SS}$ is added to the preceding one to give $\overline{SS}_{g+c}$.

The simplest application of this gray-plus-clear model of gas radiation is the case of a single gas zone surrounded by a single surface zone, the case covered for a gray gas by Eq. (4.3.51) and illustrated in the last numerical example, where radiation from methane combustion products is surrounded by a single-zone sink surface. That example will be repeated using the gray-plus-clear gas model, for which the total exchange area is

$$\frac{\overline{GS_1}}{A_1} = \frac{a_e}{a_e/\varepsilon_{G,e} + 1/\varepsilon_1 - 1} \qquad (4.3.51)$$

EXAMPLE (GRAY-PLUS-CLEAR GAS RADIATION FROM METHANE COMBUSTION PRODUCTS). The computations of the previous example, radiative flux from methane combustion products, will be repeated with the more rigorous treatment of nongrayness, and the results will be compared with the more approximate calculations for the case of a wall emissivity ε_1 of 0.4 and 0.8.

SOLUTION. Repeat the calculations given, in the earlier example, of $\varepsilon_G(pL)$, $\alpha_{G1}(pL)$ and $\varepsilon_{G,e}(pL)$ for $pL = 2 \times 0.6875$, to give $\varepsilon_G(2pL) = 0.4096$, $\alpha_{G1}(2pL) = 0.5250$, and $\varepsilon_{G,e}(2pL) = 0.3812$. Then $a_e = 0.2782/(2 - 0.3812/0.2782) = 0.4418$, and the emissivity substitute for the gray gas portion of the gray-plus-clear gas model is $0.2782/0.4418 = 0.6297$. For a single enveloping surface zone, the total exchange area comes from Eq. (4.3.51): $\overline{GS_1}/A_1 = a_e/(a_e/\varepsilon_{G,e} + 1/\varepsilon_1 - 1) = 0.4418/(0.4418/0.2782 + 1/0.8 - 1) = 0.2404$. The flux density is $\dot{Q}/A = q = (\overline{GS_1}/A)\sigma(T_G^4 - T_1^4) = 0.2404 \times 56.7 \times [(1{,}500/1{,}000)^4 - (1{,}000/1{,}000)^4] = 55.37\,\text{kW/m}^2\,[17{,}550\,\text{Btu/(ft}^2 \cdot \text{h)}]$. This is 7.6 percent lower than it is when only

the difference between ε_G and $\alpha_{G,1}$ is allowed for in finding the effect of gas nongrayness. In some problems the difference is as high as 20 percent. (Note that allowing for average humidity in air adds 5 percent to H_2O and about 2 percent to the gas emissivity.) Changing ε_1 from 0.8 to 0.4 changes the approximate solution for $\overline{GS_1}/A_1$ from 0.2501 to 0.1963 and the gray-plus-clear treatment from 0.2404 to 0.1431.

The procedures for introducing the nongray gas model can be used to convert the total exchange areas for the basic one-gas two-surface model, Eqs. (4.3.38) to (4.3.40), as used to evaluate the cases in Table 4.3.5, to the following gray-plus-clear-gas model forms:

$$\frac{\overline{S_1S_2}}{A_1} = F_{12}\varepsilon_1\varepsilon_2\left(\frac{a_e}{D_a} + \frac{1-a_e}{D_b}\right) \tag{4.3.52}$$

$$\frac{\overline{S_1S_2}}{A_1} = F_{12}\varepsilon_1^2\left\{\frac{a_e[1 - F_{12} + \rho_2(1-\varepsilon_{G,e}/a_e)(F_{12}/C_2 - 1)]}{D_a} + \frac{(1-a_e)[1 - F_{12} + \rho_2(F_{12}/C_2 - 1)]}{D_b}\right\} \tag{4.3.53}$$

$$\frac{\overline{GS_1}}{A_1} = \frac{\varepsilon_1\varepsilon_{G,e}[1/(1-\varepsilon_{G,e}/a_e] + \rho_2(F_{12}/C_2 - 1)}{D_a} \tag{4.3.54}$$

$$D_a = \frac{1}{1-\varepsilon_{G,e}/a_e} + \left(1 - \frac{\varepsilon_{G,e}}{a_e}\right)\rho_1\rho_2(1 - F_{12}C_2) - \rho_1(1-F_{12}) - \rho_2(1-F_{21})$$

$$D_b = 1 + \rho_1\rho_2\left(1 - \frac{F_{12}}{C_2}\right) - \rho_1(1-F_{12}) - \rho_2(1-F_{21})$$

$$\text{or} \qquad = \varepsilon_1\varepsilon_2 + F_{12}\left[\varepsilon_2 + \frac{\varepsilon_1(C_1-\varepsilon_2)}{C_2}\right]$$

The above relations, with the view factor F_{12} specified, may be used to convert the geometric cases of Table 4.3.5 to their more nearly correct forms with gray gas replaced by the gray-plus-clear gas model. That has been done in Table 4.3.6, which covers a moderate idealization of many practical industrial systems.

Effect of Gas Nongrayness on Refractory Zones Full allowance for the effect of gas nongrayness on enclosures in which part of the enclosing surface is radiatively adiabatic is straightforward but sometimes tedious. The term of Eq. (4.3.44) must be evaluated. It is tempting to use Eq. (4.3.45), but that is invalid because, although total radiative interchange at zone A_r is 0, the gas nongrayness makes A_r a net absorber in the spectral energy fraction a (or a_e) and a net emitter in the clear gas fraction $1 - a$. It is necessary, then, to use the basic equation

$$(\overline{GS_1})_R = \left(\overline{GS_1} + \frac{1}{1/\overline{GS_r} + 1/\overline{S_rS_1}}\right) \tag{4.3.55}$$

evaluating each of the right-hand members of a geometric system of interest, such as found in Table 4.3.5 (where A_r is A_2). As previously discussed, $\varepsilon_{G,e}/a_e$ is substituted for ε_G (or its complement for τ), and the result is weighted by the factor a_e; and for $\overline{S_rS_1}$ an additional term based on ε_G being replaced by 0 or τ by 1, with weighting $1 - a_e$, is added.

Of the cases covered in Table 4.3.5, only two will be evaluated to make A_2 represent the radiatively adiabatic zone A_r. The first is for the case of heat sink A_1 in a plane—the simulation of a slab-heating furnace. Insertion into Eq. (4.3.44) of the gray-plus-clear terms $\overline{GS_1}, \overline{GS_r}$, and $\overline{S_rS_1}$ from Table 4.3.5 (with subscript r replacing subscript 2) and rearrangement gives:

$$\left[\frac{(\overline{GS_1})_R}{A_1}\right]_{\substack{A_1 \text{ in a}\\ \text{plane}}} = \frac{\varepsilon_G}{D_1}\left[\varepsilon_1\left(\rho_r\frac{C_1}{C_r} + \frac{1}{1-\varepsilon_{G/a}}\right) + \frac{\varepsilon_r}{\dfrac{1}{\rho_1 + \dfrac{C_r}{C_1}\left(1 - \dfrac{\varepsilon_G}{a}\right)} + \dfrac{\varepsilon_G/\varepsilon_1}{a + \dfrac{(1-a)D_1}{\varepsilon_r + \rho_r\varepsilon_1 C_1/C_r}}}\right] \tag{4.3.56}$$

where $D_1 = 1/(1 - \varepsilon_G/a) - \rho_r[1 - (C_1/C_r)(\varepsilon_1 + \rho_1\varepsilon_G/a)]$. Although ε_G and a are used here, $\varepsilon_{G,e}$ and a_e should be used if allowance is to be made for the difference between gas emissivity and absorptivity. Comparison of Eq. (4.3.56) with it gray gas equivalent, Eq. (4.3.46), shows the complexity introduced by allowance for gas nongrayness. $[(\overline{GS_1})_R$ for the gray-plus-clear gas model is about 15 percent higher than for gray gas when $\varepsilon_1 = 0.8$, $\varepsilon_G = 0.3$, $C_1 = \frac{1}{3}$, $a = 0.4$, and $\varepsilon_r = 0.6$, but only 1 percent higher when $\varepsilon_r = 1$.]

The second conversion of $\overline{GS}$ to $(\overline{GS_1})_R$ will be case 4 of Table 4.3.5, the two-surface-zone enclosure with the computation simplified by assuming that the direct-view factor from any spot to a surface equals the fraction of the whole enclosure which the surface occupies (the speckled furnace model). This case can be considered an idealization of many processing furnaces such as distilling and cracking coil furnaces, with parts of the enclosure tube-covered and part left refractory. (The refractory under the tubes is not to be classified as part of the refractory zone.) Again, one starts with substitution, into Eq. (4.3.44), of the terms $\overline{GS_1}, \overline{GS_r}$, and $\overline{S_rS_1}$, from Table 4.3.5, case 4, with all terms first converted to their gray-plus-clear form. To indicate the procedure, one of the components, $\overline{S_rS_1}$, will be formulated.

$$\frac{\overline{S_rS_1}}{A_1} = a\frac{C_r\varepsilon_1\varepsilon_r}{D_4'} + (1-a)\frac{C_r\varepsilon_1\varepsilon_r}{1 - \rho_1C_1 - \rho_rC_r} = \frac{C_r\varepsilon_1\varepsilon_r}{D_4'}\left[1 + \frac{\varepsilon_G(1-a)(a-\varepsilon_G)}{1 - \rho_1C_1 - \rho_rC_r}\right]$$

With $D_4' = 1/(1 - \varepsilon_G/a) - \rho_1C_1 - \rho_rC_r$, the result of the full substitution simplifies to

$$\frac{(\overline{GS_1})_R}{A_1} = \frac{1}{C_1\left(\dfrac{1}{\varepsilon_G} - \dfrac{1}{a}\right) + \dfrac{1}{\varepsilon_1} + \dfrac{1/a - 1}{\varepsilon_1 + \varepsilon_r(C_r/C_1)}} \tag{4.3.57}$$

For a gray gas ($a = 1$) the above becomes

$$\frac{(\overline{GS_1})_R}{A_1} = \frac{1}{C_1(1/\varepsilon_G - 1) + 1/\varepsilon_1} \tag{4.3.58}$$

Equation (4.3.57) has wide applicability.

The beginning of this subsection mentions compact chambers (just treated) and long chambers as limiting cases. The latter will now be treated.

The Long Combustion Chamber If a chamber is long enough in the x direction compared to its mean hydraulic radius, the local flux from gas to wall sink comes substantially from gas at its local temperature, with $\overline{GS_1}$ [or $(GS_1)_R$] calculated by methods just described but based on a two-dimensional structure; i.e., the opposed upstream and downstream fluxes through the flow cross section will substantially cancel. That limiting case will be considered, with $(\overline{GS_1})_R/A_1$ evaluated by using local mean values of T_G and T_1. The local $(\overline{GS_1})_R$ applicable to a surface element of length dx and perimeter P is then $[(\overline{GS_1})_R/A_1]P\,dx$. Let $T_{G,\text{in}}$, $T_{G,\text{out}}$, $T_{1,\text{in}}$, and $T_{1,\text{out}}$ be specified; furnace length L is to be determined. Assume a constant sink temperature T_1. The equation of heat transfer in the furnace length element $P\,dx$ is then

$$-\dot{m}C_p\,dT_G = P\,dx\left[\frac{(\overline{GS_1})_R}{A_1}\right][\sigma(T_G^4 - T_1^4) + h(T_G - T_1)] \tag{4.3.59}$$

The second of the heat-transfer terms is an order of magnitude smaller than the first, and to permit ready integration, $h(T_G - T_1)$ will be set equal to $b\sigma(T_G^4 - T_1^4)$, from which

$$b\sigma = \frac{h}{T_G^3 + T_G^2T_1 + T_GT_1^2 + T_1^3} \cong \frac{h}{4T_{G1}^3}$$

T_{G1} is the mean value of T_G and T_1, and a 10 percent error in T_1 will make but a 1 percent error in the calculated heat transfer. Then Eq. (4.3.59) becomes

$$-\dot{m}C_p\,dT_G = P\,dx\left[\frac{(\overline{GS_1})_R}{A_1} + \frac{h}{4\sigma T_{G1}^3}\right]\sigma(T_G^4 - T_1^4) \tag{4.3.60}$$

Table 4.3.6 Conversion of Total Exchange Areas for Cases of Table 4.3.5 to Their Gray-plus-Clear Values

Case 1: Plane slab A_1 and surface A_2 completing an enclosure of gas; $F_{12} = 1$

$$\frac{\overline{S_1S_2}}{A_1} = \frac{a\varepsilon_1\varepsilon_2}{D_1} + \frac{(1-a)\varepsilon_1\varepsilon_2}{1-\rho_2(1-\varepsilon_1C_1/C_2)}$$

where

$$D_1 = \frac{1}{(1-\varepsilon_G/a)} - \rho_2\left[1 - \frac{C_1}{C_2}\left(\varepsilon_1 + \frac{\rho_1\varepsilon_G}{a}\right)\right]$$

$$\frac{\overline{GS_1}}{A_1} = \varepsilon_1\varepsilon_G\left[\frac{1/(1-\varepsilon_G/a) + \rho_2C_1/C_2}{D_1}\right]$$

$$\frac{\overline{GS_2}}{A_2} = \varepsilon_2\varepsilon_G\left[\frac{1/(1-\varepsilon_G/a) + \rho_1C_1/C_2}{D_1}\right]$$

Case 2: Infinite parallel planes, gas between; $F_{12} = F_{21} = 1$

$$\frac{\overline{S_1S_2}}{A_1} = \frac{a\varepsilon_1\varepsilon_2}{D_2} + \frac{(1-a)\varepsilon_1\varepsilon_2}{1-\rho_1\rho_2}$$

where

$$D_2 = \frac{1}{1-\varepsilon_G/a} - \left(1 - \frac{\varepsilon_G}{a}\right)\rho_1\rho_2$$

$$\frac{\overline{GS_1}}{A_1} = \varepsilon_1\varepsilon_G\left[\frac{1/(1-\varepsilon_G/a) + \rho_2}{D_2}\right]$$

Case 3: Concentric spherical or infinite cylindrical surface zones, A_1 inside; $F_{12} = 1$; $F_{21} = A_1/A_2 \equiv C_1/C_2$

$$\frac{\overline{S_1S_2}}{A_1} = \frac{a\varepsilon_1\varepsilon_2}{D_3} + \frac{(1-a)\varepsilon_1\varepsilon_2}{1-\rho_2(1-\varepsilon_1C_1/C_2)}$$

where

$$D_3 = \frac{1}{1-\varepsilon_G/a} - \rho_2\left[1 - \left(\frac{C_1}{C_2}\right)\left(\varepsilon_1 + \frac{\rho_1\varepsilon_G}{a}\right)\right]$$

$$\frac{\overline{GS_1}}{A_1} = \varepsilon_1\varepsilon_G\left[\frac{1/(1-\varepsilon_G/a) + \rho_2C_1/C_2}{D_3}\right]$$

$$\frac{\overline{GS_2}}{A_2} = \varepsilon_2\varepsilon_G\left[\frac{1/(1-\varepsilon_G/a) + \rho_2C_1/C_2}{D_3}\right]$$

Case 4: Spherical enclosure of two surface zones *or* speckled A_1:A_2 enclosure; $F_{12} = F_{22} = C_2$; $F_{21} = F_{11} = C_1$

$$\frac{\overline{S_1S_2}}{A_1} = \frac{a\varepsilon_1\varepsilon_2C_2}{D_4} + \frac{(1-a)\varepsilon_1\varepsilon_2C_2}{1-\rho_1C_1-\rho_2C_2}$$

where

$$D_4 = \frac{1}{1-\varepsilon_G/a} - \rho_1C_1 - \rho_2C_2$$

$$C_1 = \frac{A_1}{A_1+A_2}$$

$$\frac{\overline{GS_1}}{A_1} = \frac{\varepsilon_1\varepsilon_G/(1-\varepsilon_G/a)}{D_4}$$

Integration of T_G from $T_{G,\text{in}}$ to $T_{G,\text{out}}$ and of x from 0 to L, and solution for L give

$$L = \frac{\dot{m}\overline{C}_p\left(\tan^{-1}\dfrac{T_{G,\text{out}}}{T_1} - \tan^{-1}\dfrac{T_{G,\text{in}}}{T_1} - \dfrac{1}{2}\ln\dfrac{T_{G,\text{out}} - T_1T_{G,\text{in}} + T_1}{T_{G,\text{out}} + T_1T_{G,\text{in}} - T_1}\right)}{2PT_1^3\sigma\left[\dfrac{(\overline{GS_1})_R}{A_1} + \dfrac{h}{4\sigma T_{G1}^3}\right]} \tag{4.3.61}$$

Trial and error are necessary if L is specified and $T_{G,\text{out}}$ is to be found. If L is not long, axial radiative flux becomes important and a much more complex treatment is necessary. Use of a multigas zone system is one possibility.

Partially Stirred Model of Furnace Chamber Performance An equation representing an energy balance on a combustion chamber of two surface zones—a heat sink A_1 at temperature T_1 and a refractory surface A_r assumed radiatively adiabatic at T_r—is most simply solved if the total enthalpy input H is expressed as $\dot{m}\overline{C}_p(T_F - T_0)$; $\dot{m}$ is the mass rate of fuel plus air, and T_F is a pseudo-adiabatic flame temperature based on a mean specific heat from base temperature T_0 *up to the gas exit temperature* T_E rather than up to T_F. Assume that enough stirring occurs in the chamber to produce two temperatures—the heat-transfer temperature T_G and the leaving gas enthalpy temperature T_E—the two differing by an empirical amount, zero if the stirring were perfect.

Of the many ways tried to introduce this empiricism, the best is to assume that $T_G - T_E$, expressed as a ratio to T_F, is a constant Δ. Although Δ will vary with burner type, the effects of excess air and firing rate are small. At the limits of very high and low firing densities, Δ tends toward zero. These conditions excepted and in the absence of performance data on the subject furnace type, assume $\Delta = 0.08$, or

$$\frac{T_G - T_E}{T_F} = \Delta = 0.08$$

This assumption bypasses complex allowance for temperature variations in the chamber gas and for the effects of fluid mechanics and combustion kinetics, but at the cost of not permitting evaluation of **flux distribution** over the surface. The heat-transfer rate $\dot{Q}$ out of the gas is then $\dot{H} = \dot{m}\overline{C}_p(T_E - T_0)$ or $\dot{m}\overline{C}_p(T_F - T_E)$. A combination of energy balance and heat transfer, with the ambient temperature taken as the

enthalpy base temperature T_0, gives

$$(\dot{Q} =)\,\dot{H} - \dot{m}\overline{C}_p(T_E - T_0) = \dot{m}\,\overline{C}_p(T_F - T_E)$$
$$= (\overline{GS_1})_R\sigma(T_G^4 - T_1^4) + h_1A_1(T_G - T_1) \quad (4.3.62)$$

To make the relations dimensionless, divide through by $(\overline{GS_1})_R\sigma T_F^4$, and let all temperatures, expressed as ratios to T_F, be called T^*. For simplification, the following definitions of D and N_c are introduced:

$$\dot{m}\overline{C}_p/(\overline{GS_1})_R\sigma T_F^3[\equiv \dot{H}/(\overline{GS_1})_R\sigma_F^4(1 - T_0^*)]$$
$$= \text{dimensionless firing density } D$$

After the division, the left-hand side term of Eq. (4.3.62) $= D(1 - T_E^*)$ and the first right-hand side term $= T_G^{*4} - T_1^{*4}$.

$$\frac{h_1A_1}{(\overline{GS_1})_R\sigma T_F^3} = N_c, \text{ convection number (dimensionless)}$$

The equation then becomes

$$D(1 - T_E^*) = T_G^{*4} - T_1^{*4} + N_c(T_G^* - T_1^*) \quad (4.3.63)$$

The two unknowns T_G^* and T_E^* are reduced to one by expressing T_E^* in terms T_G^* of and Δ. Equation (4.3.63), with coefficients of T_G^{*4} and T_G^* collected, then becomes

$$T_G^{*4} + (D + N_c)T_G^* - [T_1^{*4} + N_cT_1^* + D(1 + \Delta)] = 0 \quad (4.3.64)$$

Although Eq. (4.3.64) is a quartic equation, it is capable of explicit solution. Trial and error enter, however, because $(\overline{GS_1})_R$ and $\overline{C}_p$ are mild functions of T_G and related T_E, respectively, and a preliminary guess of T_G is necessary. Ambiguity can exist in the interpretation of terms. If part of the enclosure surface consists of screen tubes over the chamber gas exit to a convection section, radiative transfer to those tubes is included in the chamber energy balance but convection is not, because it has no effect on the chamber gas temperature. Although the results must be considered approximations, depending as they do on the empirical Δ, the equation may be used to find the effect of firing rate, excess air, and air preheat on efficiency. With some performance data available, the small effect of various factors on Δ may be found.

For the commonly encountered case of the sink consisting of a row of tubes mounted on a refractory wall, A_1 is the area of the whole plane in which the tubes lie, T_1 is tube surface temperature, and ε_1 is the effective emissivity of the tube-row-refractory-wall combination, as in the earlier numerical example associated with Fig. 4.3.6, where $\varepsilon_1 = 0.702$. A further simplification is to replace A_1/A_T by C, the "cold" fraction of the wall ($A_T \equiv A_1 + A_r$).

With T_G^* known, the chamber efficiency η_G based on heat transfer from the gas is given by

$$\eta_G = \frac{(1 - T_G^* + \Delta)}{1 - T_O^*} \quad (4.3.65)$$

In the absence of heat losses, this is equal to the efficiency based on energy to the sink. It is expressed as

$$\eta_G = \frac{(GS_1)_R\sigma(T_G^4 - T_1^4) + h_1A_1(T_G - T_1)}{\dot{H}} \quad (4.3.66)$$

Solution of Eq. (4.3.63) gives the relation between T_G^* and D, and substituting the value of T_G^* into either Eq. (4.3.65) or Eq. (4.3.66) provides the dependence of η_G on D.

Furnace Chamber Performance—General Although the chamber efficiency η depends on D, N_c, and T_1^*, the reduced firing density D is the dominant factor; it makes allowance for such operating variables as fuel type, excess air or air preheat—which affect flame temperature or gas emissivity, for fractional occupancy of the walls by sink surfaces, and for sink emissivity. Variation in the normalized sink temperature T_1^* has little effect until it exceeds 0.3; N_c, though significant, is secondary.

Solution of Eq. (4.3.63) gives the relation between D and T_G^*, and Eqs. (4.3.65) and (4.3.66) give the relation between η_G and D. As an example, Fig. 4.3.6 gives D versus η_G. Approximate operating regimes of various classes of furnaces are shown in Table 4.3.7. Note the significant properties of the functions presented: (1) As firing rate D goes down, η_G rises; T_G^* approaches T_1^* in the limit as D decreases to zero. (2) Changing T_1^* has a large effect only when it exceeds about 0.4. (3) As the furnace walls approach complete coverage by a black sink ($C = \varepsilon_1 = 1$), $\overline{GS_1}$ becomes ε_GA_T and $D \propto 1/\varepsilon_G$. Thus, at very high firing rates where η_G approaches inverse proportionality to D, the efficiency of heat transfer varies directly as ε_G (gas-turbine chambers), but at low firing rates ε_G has relatively little effect. (4) When $C\varepsilon_1 \ll 1$ because of a nonblack sink or much refractory surface, the effect of changing flame emissivity is to produce a much less than proportional effect on heat flux. The regimes of operation of different practical combustion systems are given in Table 4.3.7.

Equations (4.3.63) to (4.3.66) predict the effects of excess air, air preheat, and fuel quality on performance, through the effect on T_F; through $\overline{GS_1}$ they show the effect of gas and sink emissivity and the fraction of the chamber walls occupied by heat sink. They serve as a framework for correlating the performance of furnaces with flow patterns—plug flow, parabolic profile, and recirculatory flow—differing from

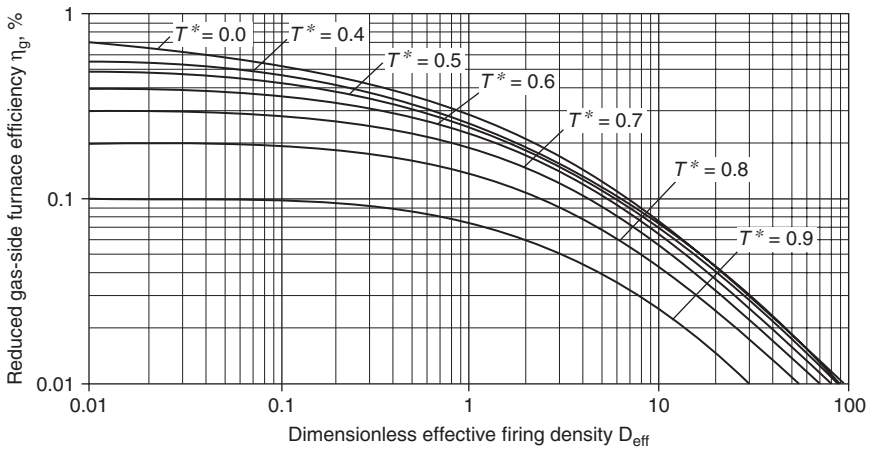

Fig. 4.3.6 Reduced gas-side furnace efficiency versus effective firing density for well-stirred combustion chamber model. $\Delta = 0$; $T^* = 0.0, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9$.

Table 4.3.7 Operational Domains for Representative Process Furnaces and Combustors

Domain	Furnace or combustor type	Dimensionless sink temperature	Dimensionless firing density
A	Oil processing furnaces; radiant section of oil tube stills and cracking coils	$T^* \approx 0.4$	$0.1 < D_{\text{eff}} < 1.0$
B	Domestic boiler combustion chambers	$T^* \approx 0.2$	$0.5 < D_{\text{eff}} < 1.1$
C	Glass furnaces	$0.7 < T^* < 0.8$	$0.035 < D_{\text{eff}} < 0.8$
D	Soaking pits	$T^* \approx 0.6$	$0.7 < D_{\text{eff}} < 1.1$
E	Gas-turbine combustors	$0.4 < T^* < 0.7$	$4.0 < D_{\text{eff}} < 25.0$

the well-stirred model (Hottel and Sarofim, Chap. 14). As expected, plug-flow furnaces show somewhat higher efficiency, mild recirculation types somewhat lower efficiency, and strong recirculation furnaces an efficiency closely similar to that of the well-stirred model.

Refractory Temperature T_r Though the average value of T_r in a combustion chamber is not involved in the evaluation of T_G or η, it is sometimes of interest. It assumes a mean value between T_G and T_1, given by

$$\left(\frac{T_r}{T_G}\right)^4 = \frac{1 + E(T_1/T_G)^4}{1 + E}$$

For the speckled furnace gray gas model

$$E = C\varepsilon_1\left(\frac{1}{\varepsilon_G} - 1\right)$$

Allowance is made for the difference between emissivity and absorptivity by changing ε_G to $\varepsilon_{G,e}$ in the above equation. For the gray-plus-clear-gas model,

$$E = C\varepsilon_1\left[\frac{1}{\varepsilon_G} - \frac{1}{a} + \frac{1/a - 1}{C\varepsilon_1 + (1 + C)\varepsilon_R}\right]$$

4.4 TRANSMISSION OF HEAT BY CONDUCTION AND CONVECTION

Notation and Units The units are based on feet, pounds, hours, degrees Fahrenheit, and Btu. Any other consistent set may be used in the dimensionless relations given, but for the dimensional equations the units of this table must be used.

A = area of heat-transfer surface, ft^2
A_i = inside area
A_o = outside area
A_m = average value of A, ft^2
a = empirical constant
C_p = specific heat at constant pressure, Btu/lb · °F
D = diameter, ft
D_o = outside diameter, ft
D_i = inside diameter, ft
D′ = diameter, in
D'_o = outside diameter, in
D'_i = inside diameter, in
G = mass velocity, equals w/S, lb/h · ft^2 of cross section occupied by fluid
$G_{\max}$ = mass velocity through minimum free area in a row of pipes normal to fluid stream, lb/h · ft^2
g_c = conversion factor, equal to 4.18×10^8 (mass lb)(ft)/(force lb)(h)^2
g_L = local acceleration due to gravity, 4.18×10^8 ft/h^2 at sea level
h = local individual coefficient of heat transfer, equals $dq/dA\ \Delta t$, Btu/h(ft^2)(°F)diff
$h_c + h_r$ = combined coefficient by conduction, convection, and radiation between surface and surroundings
h_m = mean value of h for entire surface, based on $(\Delta t)_m$
$h_{\text{a.m.}}$ = average h, arbitrarily based on arithmetic-mean temperature difference
h_s = heat-transfer coefficient through scale deposits
J = mechanical equivalent of heat, 778 ft · lb/Btu
K = empirical constant
k = thermal conductivity, Btu/h · ft · °F

$$k_m = -\frac{1}{t_1 - t_2}\int_1^2 k\,dt$$

k_f = k at the "film" temperature, $t_j = (t + t_w)/2$
l = thickness of material normal to heat flow, ft
L = length of heat-transfer surface, heated length, ft
N = number of rows of tubes
N_{Gr} = Grashof number, $L_c^3\rho_f^2 g_L \beta_f (\Delta t)_s/\mu_f^2$
q = total rate of heat flow, Btu/h
$\dot{\mathbf{q}}$ = heat-flux vector, Btu/h · ft^2
$\dot{\mathbf{q}}_x$ = x component of heat flux vector
R = thermal resistances, $1/(UA)$, $1/(hA)$, $1/(h_c + h_r)A_0$
$\mathcal{R}$ = recovery factor
r = radius, ft
S = cross section, filled by fluid, in plane normal to direction of fluid flow, ft^2
T = temperature, °R = $t + 460$
T_1, T_2 = inlet and outlet bulk temperatures, respectively, of warmer fluid, °F
t = bulk temperature (based on heat balance), °F
$t_{\text{a.w.}}$ = temperature of adiabatic wall
t_∞ = temperature at infinity

t_w = wall temperature, °F
t_1, t_2 = inlet and outlet bulk temperatures of colder fluid, °F
t_i, t_o = temperatures of fluid inside and outside, °F
$t_f = (t + t_w)/2$
t_{sat} = saturation temperature, °F
U = overall coefficient of heat transfer, Btu/h · ft² · °F; U_i, U_o based on inside and outside surface, respectively
V = mean velocity, ft/h
V_s = average velocity, volumetric rate divided by cross section filled by fluid, ft/s
V_{sm} = maximum velocity, through minimum cross section, ft/s
x = one of the axes of a Cartesian reference frame, ft
$X = (t_2 - t_1)/(T_1 - t_1)$
w = mass rate of flow per tube, lbm/h/tube
$Z = (T_1 - T_2)/(t_2 - t_1)$
β = volumetric coefficient of thermal expansion, °F^{-1}
Γ = mass rate of flow, lbm/(h) (ft of wetted periphery measured on a plane normal to direction of fluid flow); = $w/\pi D$ for a vertical and $w/2L$ for a horizontal tube
γ = ratio of specific heats, c_p/c_v; 1.4 for air
$\mathcal{R}$ = gradient operator
Δt = temperature difference, °F
$(\Delta t)_{ave}$, $(\Delta t)_{l.m.}$ = arithmetic and logarithmic means of terminal temperature differences, respectively, °F
$(\Delta t)_m$ = true mean value of the terminal temperature differences, °F
$(\Delta t)_o$ = overall temperature difference, °F
$(\Delta t)_s$ = temperature difference between surface and surroundings, °F
λ = latent heat (enthalpy) of vaporization, Btu/lb
μ = viscosity at bulk temperature, lbm/h · ft; equals 2.42 times centipoises; equals 116,000 times viscosity in (lb force)(s)/ft²
μ_f = viscosity, lbm/h · ft, at arithmetic mean of wall and fluid temperatures
μ_w = viscosity at wall temperature, lbm/h · ft
ρ = density, lbm/ft³
σ = surface tension, lb force/ft

Subscripts:

l = liquid
v = vapor

Preliminary Statements The transfer of heat is usually considered to occur by three processes:

1. **Conduction** is the transfer of heat from one part of a body to another part or to another body by short-range interaction of molecules and/or electrons.
2. **Convection** is the transfer of heat by the combined mechanisms of fluid mixing and conduction.
3. **Radiation** is the emission of energy in the form of electromagnetic waves. All bodies above absolute zero temperature radiate. Radiation incident on a body may be absorbed, reflected, and transmitted. (See Sec. 4.3.)

CONDUCTION

See Tables 4.4.1 to 4.4.7 and 4.4.10

The **basic Fourier conduction law** for an isotropic material is

$$\dot{\mathbf{q}} = -k\nabla t \tag{4.4.1}$$

In cartesian coordinates, the x component of this equation is $\dot{\mathbf{q}}_x = -k(\partial t/\partial x)$, and if the heat flow is essentially unidimensional, $\mathbf{q} = \dot{\mathbf{q}}A(x) = -kA(x)(dt/dx)$. This states that the steady-state rate of heat conduction q is proportional to the cross-sectional area $A(x)$ normal to the direction of flow and to the temperature gradient —partial—t/—partial—x along the conduction path. The proportionality constant k is called the **"true" thermal conductivity** of the material.

The thermal conductivity of a given material varies with temperature, and the mean thermal conductivity is defined by

$$k_m = \frac{1}{t'_0 - t'_i}\int_{t_0}^{t_i} k\,dt$$

For unidimensional heat flow through a material of thickness l

$$q\int_0^l \frac{dx}{A(x)} = \int_{t_i'}^{t_0'} k\,dt = k_m(t_i' - t_0') \tag{4.4.2}$$

With an obvious definition for the mean area:

$$\frac{q}{A_m} = k_m(t_i' - t_0')/l$$

For flat plates, $A_m = A_i = A_0$; for hollow cylinders, $A_m = (A_0 - A_i)/\ln(A_0/A_i)$; for hollow spheres, $A_m = \sqrt{A'A_0}$. For more complex shapes, Eq. (4.4.1) must be employed. For other configurations, mean areas may often be found elsewhere, e.g., Kutateladze and Borishanskei, "A Concise Encyclopedia of Heat Transfer," Pergamon Press, pp. 36–44.

Extended Surfaces Fin efficiency is defined as the ratio of the mean temperature difference from surface to fluid divided by the temperature difference from fin to fluid at the base or root of the fin. Graphs of fin efficiency for extended surfaces of various types are given by Gardner (*Trans. ASME,* **67,** pp. 621–628, 1945) and in numerous texts, e.g., by Eckert and Drake, pp. 92–93. Heat-transfer coefficients for various extended surfaces are given by Kays and London.

CONDUCTION AND CONVECTION

Phenomena of Heat Transmission In many practical cases of heat transmission—e.g., boilers, condensers, the cooling of engine cylinders—heat is transmitted from one fluid to another through a wall separating the two. The processes occurring in the fluids may be extremely complex. However, to facilitate discussion, it is convenient to imagine that most of the fluid offers no resistance to heat transmission but that a thin film of fluid adjacent to the wall offers considerable resistance. This situation is depicted in Fig. 4.4.1. Then, by definition,

$$q = h_iA_i(t_i - t_i') = \frac{k}{l}A_m(t_i' - t_0) = h_0A_0(t_0' - t_0)$$

The terms h_i and h_0 are the **film coefficients,** or **unit conductances,** of the films f_1 and f_2, respectively, and k is the thermal conductivity of the wall. Since q, A, $t_i - t_i'$, and $t_0' - t_0$ are susceptible to direct measurement, h_i and h_0 are simply defined quantities and the propriety of the above equation does not rest upon the heuristic film concept. Indeed, for laminar flow, the film concept is a gross misrepresentation, and yet the definition of a film coefficient (or heat-transfer coefficient) remains convenient and valid.

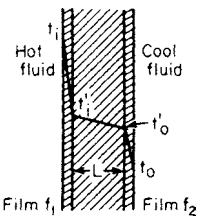

Fig. 4.4.1 Temperature gradients in heat flow through a wall.

SOURCE: F. G. Keyes, *Tech. Rept. 37,* Project Squid (Apr. 1, 1952).

If t_i' and t_0' are eliminated from the above equation, a relation is obtained for steady flow through several resistances in series:

$$q = \frac{t_i - t_0}{1/(h_iA_i) + 1/(kA_m) + 1/(h_0A_0)} \tag{4.4.3}$$

Each of the terms in the denominator represents a resistance to heat transfer. There may also be a resistance, $1/(h_sA_s)$, due to the presence of a scale deposit on the surface. Thus, if the overall heat transfer is given by $q = UA(t_i - t_0)$, then the total thermal resistance is given by

$$1/(UA) = 1/(h_iA_i) + 1/(kA_m) + 1/(h_oA_o) + 1/(h_sA_s) \tag{4.4.4}$$

Coefficients for scale deposits are given in Table 4.4.9.

Mean Temperature Difference The basic equation for any steadily operated heat exchanger is $dq = U(\Delta t)_o\, dA$, in which U is the overall coefficient [Eq. (4.4.4)], $(\Delta t)_o$ is the overall temperature difference between hot and cold fluids, and dq/dA is the local rate of flow per unit surface. In order to apply this relation to a finite exchanger, it is necessary to integrate it. The assumptions usually made are constant U, constant mass rates of flow, no changes in phase, constant specific heats, and negligible heat losses. The resulting equation for parallel or countercurrent flow of fluids is

$$q = UA(\Delta t)_m = UA[(\Delta t)_{01} - (\Delta t)_{02}]/\ln\,[(\Delta t)_{01}/(\Delta t)_{02}] \tag{4.4.5a}$$

in which $(\Delta t)_m$ is the logarithmic mean of the terminal temperature differences, $(\Delta t)_{01}$ and $(\Delta t)_{02}$, between hot and cold fluid. The value of UA is evaluated from the resistance concept of Eq. (4.4.4) and the values of h are obtained from the following pages. For more complicated flow geometries, the logarithmic mean is not appropriate, and the true mean temperature difference may be obtained from Fig. 4.4.2, where

$$Y = \text{ordinate} = \frac{\text{true mean temp difference}}{\text{logarithmic mean temp difference for counterflow}}$$

For the other symbols see p. 4-79. (From *Trans. ASME,* **62,** 1940, pp. 283–294.)

The above discussion focuses on the concepts of an overall coefficient and a mean-temperature difference. An alternative approach focuses on the concepts of effectiveness and the number of transfer units. The alternatives are basically equivalent, but one or the other may enjoy a computational advantage. The latter method is presented in detail by Kays and London and by Mickley and Korchak (*Chem. Eng.,* **69,** 1962, pp. 181–188 and 239–242).

EXAMPLE. Assume an exchanger in which the hot fluid enters at 400°F and leaves at 327°F; the cold fluid enters at 100°F and leaves at 283°F. Assuming U independent of temperature, what will be the true mean temperature difference from hot to cold fluid, (1) for counterflow and (2) for a reversed current apparatus with one well-baffled pass in the shell and two equal passes in the tubes?

1. With counterflow, the terminal differences are 400 − 283 = 117°F and 327 − 100 = 227°F; the logarithmic mean difference is 110/0.662 = 166°F.

2. $Z = (400 - 327)/(283 - 100) = 0.4$; $X = (283 - 100)/(400 - 100) = 0.61$; from section A of Fig. 4.4.2, $Y = 0.9 = (\Delta t)_m/166$; $(\Delta t)_m = 149$°F.

If one of the temperatures remains constant, as in a condenser or in an evaporative cooler, Eq. (4.4.5a) applies for parallel flow, counterflow, reversed current, and cross flow.

If U varies considerably with temperature, the apparatus should be considered to be divided into stages, in each of which the variation of U with temperature or temperature difference is linear. Then for parallel or counterflow operation, the following relation may be applied to each stage:

$$q = \frac{A[U_2(\Delta t)_{01} - U_1(\Delta t)_{02}]}{\ln[U_2(\Delta t)_{01}/U_1(\Delta t)_{02}]} \tag{4.4.5b}$$

Colburn (*Ind. & Eng. Chem.,* **25,** 1933, pp. 873–877) has shown that this equation is exact if U varies linearly with temperature.

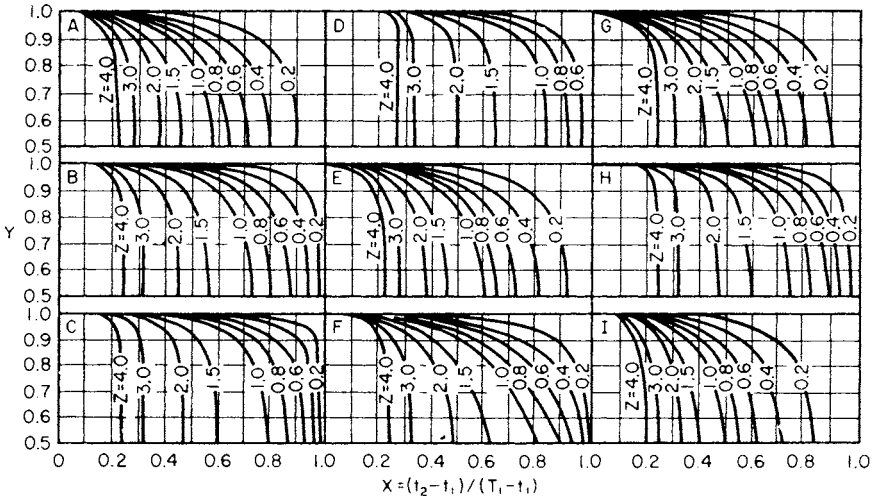

Fig. 4.4.2 (*A*) One shell pass and two tube passes; (*B*) two shell passes and four tube passes; (*C*) three shell passes and six tube passes; (*D*) four shell passes and eight tube passes; (*E*) cross flow, one shell pass and one tube pass, both fluids mixed; (*F*) single-pass cross-flow exchanger, both fluids unmixed; (*G*) single-pass cross-flow exchanger, one fluid mixed, the other unmixed; (*H*) two-pass cross-flow exchanger, shell fluid mixed, tube fluid unmixed, shell fluid first crossing the second tube pass; (*I*) same as (*H*), but shell fluid first crosses the first tube pass.

FILM COEFFICIENTS

The important physical properties which affect film coefficients (see Sec. 4.1) are thermal conductivity, viscosity, density, and specific heat. Factors within the control of the designer include fluid velocity and shape and arrangement of the heating surface. With forced flow of gases or water, under the conditions usually met in practice, the flow is turbulent (see Sec. 3) and under these conditions the film coefficient can be greatly increased by increasing the velocity of the fluid at the expense of a greater power requirement. For a given velocity and fluid, the film coefficient depends upon the direction of flow of fluid relative to the heating surface. With free or natural convection, for a given arrangement of surface, the film coefficient depends on an additional fluid property, the coefficient of thermal expansion, on the temperature difference between surface and fluid, and on the local gravitational acceleration. With forced convection at low rates of flow, particularly with viscous fluids such as oils, laminar motion may prevail and the film coefficient depends on thermal conductivity, specific heat, mass rate of flow per tube, and length and diameter of the tube. In any event, the film coefficients h are correlated in terms of dimensionless groups of the controlling factors.

Turbulent Flow inside Clean Tubes (No Change in Phase), $DG/\mu_f > 7{,}000$

$$\frac{h_m}{C_pG}\left(\frac{C_p\mu_f}{k_f}\right)^{2/3} = \frac{0.023}{(DG/\mu_f)^{0.2}} \tag{4.4.6a}$$

For L/D less than 60, multiply the right-hand side of Eqs. (4.4.6a), (4.4.6b), and (4.4.6c) by $1 + (D/L)^{0.7}$.

Turbulent Flow of Gases inside Clean Tubes, $DG/\mu_f > 7{,}000$

$$h_m = 0.024C_pG^{0.8}/(D_i')^{0.2} \tag{4.4.6b}$$

Turbulent Flow of Water inside Clean Tubes, $DG/\mu_f > 7{,}000$

$$h_m = 160(1 + 0.012t_f)V_s^{0.8}/(D_i')^{0.2} \tag{4.4.6c}$$

Turbulent Flow of Liquid Metals inside Clean Tubes, $C_p\mu/k < 0.05$ The equation of Sleicher and Tribus ("Recent Advances in Heat Transfer," p. 281, McGraw-Hill, 1961) is recommended for isothermal tube walls:

$$\frac{h_mD}{k} = 6.3 + 0.016\left(\frac{DGC_p}{k}\right)^{0.91}\left(\frac{C_p\mu}{k}\right)^{0.3} \tag{4.4.6d}$$

Turbulent Flow of Gases or Water in Annuli Use Eq. (4.4.6b) or (4.4.6c), with D' taken as the clearance, inches. If the clearance is comparable to the diameter of the inner tube, see Kays, Crawford, and Weigand.

Water in Coiled Pipes Multiply h_m for the staight pipe by the term $(1 + 3.5D_i/D_c)$, where D_i is the inside diameter of the pipe and D_c is that of the coil.

Turbulent Boundary Layer on a Flat Plate, $V_\infty\rho_f x/\mu_f > 4 \times 10^5$, no pressure gradient

$$\frac{h}{\rho_fC_pV_\infty}\left(\frac{C_p\mu}{k}\right)^{2/3} = \frac{0.0148}{(\rho_fV_\infty x/\mu_f)^{0.2}} \tag{4.4.6e}$$

$$\frac{h_m}{\rho_fC_pV_\infty}\left(\frac{C_p\mu}{k}\right)_f^{2/3} = \frac{0.0185}{(\rho_fV_\infty L/\mu_f)^{0.2}} \tag{4.4.6f}$$

Fluid Flow Normal to a Single Tube, D_oG/μ_f from 1,000 to 50,000

$$\frac{h_mD_o}{k_f} = 0.26\left(\frac{D_oG}{\mu_f}\right)^{0.6}\left(\frac{C_p\mu}{k}\right)_f^{0.3} \tag{4.4.7}$$

Gas Flow Normal to a Single Tube, D_oG/u_f from 1,000 to 50,000

$$h_m = 0.30C_pG^{0.6}/(D_o')^{0.4} \tag{4.4.7a}$$

Fluid Flow Normal to a Bank of Staggered Tubes, $D_oG_{\max}/\mu_f$ from 2,000 to 40,000

$$\frac{h_mD_o}{k_f} = K\left(\frac{C_p\mu}{k}\right)_f^{1/3}\left(\frac{D_oG_{\max}}{\mu_f}\right)^{0.6} \tag{4.4.8}$$

Values of K are given in Table 4.4.8.

Water Flow Normal to a Bank of Staggered Tubes, $D_oG_{\max}/\mu_f$ from 2,000 to 40,000

$$h_m = 370(1 + 0.0067t_f)V_{sm}^{0.6}/(D_o')^{0.4} \tag{4.4.8a}$$

For baffled exchangers, to allow for leakage of fluids around the baffles, use 60 percent of the values of h_m from Eq. (4.4.8); for tubes in line, deduct 25 percent from the values of h_m given by Eq. (4.4.8).

Water Flow in Layer Form over Horizontal Tubes, $4\Gamma/\mu < 2{,}100$

$$h_{a.m.} = 150(\Gamma/D_o')^{1/3} \tag{4.4.9}$$

for Γ ranging from 100 to 1,000 lb of water per h per ft (each side).

Water Flow in Layer down Vertical Tubes, $w/\pi D > 500$

$$h_m = 120\Gamma^{1/3} \tag{4.4.9a}$$

Table 4.4.3 Thermal Conductivities of Miscellaneous Solid Substances*

* The thermal conductivity of different materials varies greatly. For metals and alloys k is high, while for certain insulating materials, such as glass wool, cork, and kapok, it is very low. In general, k varies with the temperature, but in the case of metals, the variation is relatively small. With most other substances, k increases with rising temperatures, but in the case of many crystalline materials, the reverse is true.

† With heat flow parallel to the grain, k may be 2 to 3 times that with heat flow perpendicular to the grain, the values for wool are taken chiefly from J. D. MacLean, *Trans. ASHRAE,* **47,** 1941, p. 323.

Heat Transfer to Gases Flowing at Very High Velocities If a nonreactive gas stream is brought to rest adiabatically, as at the true stagnation point of a blunt body, the temperature rise will be

$$t_s - t_\infty = V^2/(2g_cJC_p) \tag{4.4.9b}$$

where t_s is the stagnation temperature and t_∞ is the temperature of the free stream moving at velocity V. At every other point on the body, the gas temperature is influenced by convection, viscous dissipation, and thermal conduction. At an insulated surface, the gas temperature will therefore be neither the free-stream temperature nor the stagnation temperature. In general, the rise in gas temperature will be given by

$$t_{aw} - t_\infty = \mathcal{R}(t_s - t_\infty) = \mathcal{R}V^2/(2g_cJC_p) \tag{4.4.9c}$$

where t_{aw} is the gas temperature at the adiabatic wall and $\mathcal{R}$ is the recovery factor.

If a given point on the surface of a body is not at the temperature t_{aw} given by Eq. (4.4.9c) with the proper local value of $\mathcal{R}$ inserted, there will be a transfer of heat to or from the body. This suggests defining the coefficient of heat transfer in the usual way, except that the difference $t_w - t_{aw}$ should be used:

$$q/A = h(t_\infty - t_{aw}) = h\{t_w - [t + \mathcal{R}V^2/(2g_cJC_p)]\} \tag{4.4.9d}$$

where t_w is the surface temperature of the heated wall. With this modification, it is found that the correlations for h are nearly independent of Mach number; e.g., Eq. (4.4.6a) may be used for turbulent, compressible flow in a pipe. Obviously, $\mathcal{R} = 1.0$ at a forward stagnation point. For flows parallel to surfaces which have little or no curvature in the direction of flow, the following are recommended:

Laminar flow $$\mathcal{R} = \left(\frac{C_p\mu}{k}\right)^{1/2}$$

Turbulent flow $$\mathcal{R} = \left(\frac{C_p\mu}{k}\right)^{1/3}$$

Very little is presently known about point values of the recovery factor for flow over more complex shapes. Thus, special thermocouples

should be used to measure the temperature of high-velocity gas streams (Hottel and Kalitinsky, *Jour. Applied Mechanics,* 1945, pp. A25–A32; and Franz, *Jahrb* 1938 *deut. Luftfahrt-Forsch* II, pp. 215–218). Eckert (*Trans. ASME,* **78,** 1956, pp. 1273–1283) recommends that all property values be evaluated at a film temperature defined by

$$t_f = (t_\infty + t_w)/2 + 0.22(t_{aw} - t_\infty) \tag{4.4.9e}$$

Nielsen (*NACA Wartime Rep.* L-179) gives graphs for predicting the heat transfer and pressure drop for airflow at Mach numbers up to 1.0, in tubes having a uniform wall temperature.

Heat transfer from a reacting gas to a surface is treated by Lees ("Recent Advances in Heat and Mass Transfer," p. 161, McGraw-Hill).

LAMINAR FLOW

Pipe Flow, $DG/\mu < 2{,}100$. Use the Sieder-tate modification of the Graetz equation for isothermal tube walls and $wC_p/kL > 10$:

$$h_{a.m.}D/k = 2.0(wC_p/kL)^{1/3}(\mu/\mu_w)^{0.14} \tag{4.4.10}$$

or

$$(h_{a.m.}/C_pG)(C_p\mu/k)^{2/3}(\mu_w/\mu)^{0.14} = 1.85(D/L)^{1/3}(DG/\mu)^{-2/3} \tag{4.4.10a}$$

As shown in Fig. 4.4.3, as DG/μ increases from 2,100 to 7,000, the effect of L/D diminishes and finally becomes negligible for $L/D > 60$.

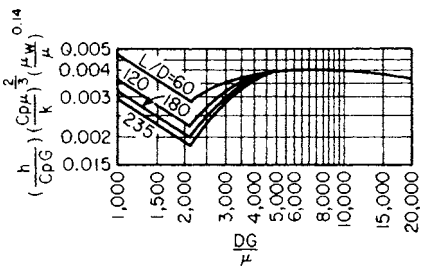

Fig. 4.4.3 Heating and cooling of viscous oils flowing inside tubes. [The curves for D_G/μ below 2,100 are based on Eq. (4.4.10).]

Laminar Boundary Layer on a Flat Plate. $\rho V_\infty x/\mu < 4 \times 10^5$, isothermal plate, no pressure gradient

$$\frac{h}{\rho_f C_p V_\infty}\left(\frac{C_p\mu}{k}\right)_f^{2/3} = \frac{0.332}{(\rho_f V_\infty x/\mu_f)^{1/2}} \tag{4.4.10b}$$

$$\frac{h_m}{\rho_f C_p V_\infty}\left(\frac{C_p\mu}{k}\right)_f^{2/3} = \frac{0.664}{(\rho_f V_\infty L/\mu_f)^{1/2}}$$

* From standards of Tubular Exchanger Manufacturers Assoc., 1952.
† Delaware, East River (NY), Mississippi, Schuylkill, and New York Bay.

Natural Convection Heat transfer by natural convection is governed by relations of the form

$$\frac{h_m L_c}{k_f} = f[L_c^3 \rho_f^2 g_L \beta_f (\Delta t)_s / \mu_f^2,\ (C_p \mu / k)_f] \tag{4.4.11}$$

where β_f is defined by the equation $\rho_f = \rho_\infty[1 - \beta_f(\Delta t)_s]$. For perfect gases, $\beta_f = 1/T_\infty$. The dimensionless group $L_c^3 \rho_f^2 g_L \beta_f (\Delta t)_s / \mu_f^2 \equiv N_{Gr}$ represents the ratio of the product (inertial force times buoyant force) to (viscous force squared).

If the flow is of the laminar boundary layer type and if $(C_p\mu/k)_f > 1$, an effective correlation is

$$\frac{h_m L_c}{k_f} = B_1[N_{Gr}(C_p\mu/k)_f]^{0.25} \tag{4.4.11a}$$

where B_1 is a weak function of $(C_p\mu/k)_f$. Similarly, for $(C_p\mu/k)_f < 1$,

$$\frac{h_m L_c}{k_f} = B_2[N_{Gr}(C_p\mu/k)_f^2]^{0.25} \tag{4.4.11b}$$

VERTICAL FLAT PLATES. For this case, $L_c = L$ and the flow of the laminar boundary layer type will be laminar if

$$(C_p\mu/k)_f > 1 \qquad 10^9 > N_{Gr}(C_p\mu/k)_f > 10^4$$
$$(C_p\mu/k)_f < 1 \qquad ? > N_{Gr}(C_p\mu/k)_f^2 > 10^4$$

Lefevre (*Rept. Heat* 113, National Engineering Laboratory, Great Britain, Aug. 1956) gives an interpolation formula which contains the proper limiting forms and is in complete agreement with existing numerical results:

$$\frac{h_m L_c}{k_f} = \left[\frac{N_{Gr}(C_p\mu/k)^2}{2.435 + 4.884(C_p\mu/k)_f^{1/2} + 4.953(C_p\mu/k)_f}\right]^{0.25} \tag{4.4.11c}$$

If $(C_p\mu/k)_f$ is in the vicinity of unity and if $N_{Gr}\ (C_p\mu/k)_f > 10^9$, the boundary layer will be turbulent and

$$\frac{hL}{k_f} = 0.13[N_{Gr}(C_p\mu/k)_f]^{1/3} \tag{4.4.11d}$$

HORIZONTAL CYLINDERS. Replace L in the vertical flat plate formulas by $\pi D_o/2$.

HEATED HORIZONTAL PLATES FACING UPWARD OR COOLED HORIZONTAL PLATES FACING DOWNWARD.

$$2 \times 10^7 > N_{Gr}(C_p\mu/k)_f > 10^5$$
$$\frac{h_m L}{k_f} = 0.54[N_{Gr}(C_p\mu/k)_f]^{0.25} \tag{4.4.11e}$$

$$N_{Gr}(C_p\mu/k)_f > 2 \times 10^7$$
$$\frac{h_m L}{k_f} = 0.14[N_{Gr}(C_p\mu/k)_f]^{1/3} \tag{4.4.11f}$$

HEATED HORIZONTAL PLATES FACING DOWNWARD OR COOLED HORIZONTAL PLATES FACING UPWARD.

$$3 \times 10^{10} > N_{Gr}(C_p\mu/k)_f > 3 \times 10^5$$
$$\frac{hL}{k_f} = 0.27[N_{Gr}(C_p\mu/k)_f]^{0.25} \qquad (4.4.11g)$$

Equations (4.4.11e) to (4.4.11g) should not be considered reliable if $(C_p\mu/k)_f$ differs greatly from unity.

For more complex systems, it is best to consult experimental data (Gebhart et al.).

For any particular fluid, the above equations may be greatly simplified. For air which is at room temperature and atmospheric pressure and is subjected to the gravitational attraction at sea level:

VERTICAL PLATES.

$$10^3 > L^3(\Delta t)_s > 10^{-2}$$
$$h_m = 0.28[(\Delta t)_s/L]^{0.25} \qquad (4.4.12a)$$
$$L^3(\Delta t)_s > 10^3$$
$$h_m = 0.19(\Delta t)_s^{1/3} \qquad (4.4.12b)$$

HORIZONTAL CYLINDERS.

$$10^2 > D^3(\Delta t)_s > 10^{-3}$$
$$h_m = 0.25[(\Delta t)_s/D]^{0.25} \qquad (4.4.12c)$$
$$D^3(\Delta t)_s > 10^2$$
$$h_m = 0.19(\Delta t)_s^{1/3} \qquad (4.4.12d)$$

HEATED HORIZONTAL PLATES FACING UPWARD OR COOLED HORIZONTAL PLATES FACING DOWNWARD.

$$10 > L^3(\Delta t)_s > 0.1$$
$$h_m = 0.27[(\Delta t)_s/L]^{0.25} \qquad (4.4.12e)$$
$$10^4 > L^3(\Delta t)_s > 10$$
$$h_m = 0.22(\Delta t)_s^{1/3} \qquad (4.4.12f)$$

HEATED HORIZONTAL PLATES FACING DOWNWARD OR COOLED HORIZONTAL PLATES FACING UPWARD.

$$10^4 > L^3(\Delta t)_s > 0.1 \qquad (4.4.12g)$$
$$h_m = 0.12[(\Delta t)_s/L]^{0.25}$$

Condensing Vapors If the condensate of a single pure vapor, saturated or supersaturated, wets the surface, film-type condensation is obtained. The rate of heat transfer equals $h_m(\Delta t)_m$, where $(\Delta t)_m$ is the mean difference between the saturation temperature and the temperature of the surface. As long as the condensate flow is laminar ($4\Gamma/\mu_f < 2{,}100$), the following dimensionless equations may be used:

For **horizontal tubes,**

$$h_m D/k = 0.73[D^3\rho^2\lambda g_L/k\mu_f N(\Delta t)_m]^{0.25}$$
$$= 0.76(D^3\rho^2 g_L/\mu_f\Gamma)^{1/3} \qquad (4.4.13)$$

For **vertical tubes,**

$$h_m L/k = 0.94[L^3\rho^2\lambda g_L/k\mu_f(\Delta t)_m]^{0.25}$$
$$= 0.93(L^3\rho^2 g_L/\mu_f\Gamma)^{1/3} \qquad (4.4.13a)$$

The equations show that a tube of given dimensions, for the usual case where $L/(ND)$ is greater than 2.76, is more effective in a horizontal than in a vertical position. Thus for $L/(ND) = 100$, a horizontal tube gives an average h which is 2.5 times that for a vertical tube. Since there is but little variation in the thermal conductivity or viscosity of the condensate at the condensing temperature at 1 atm, there is little variation in h_m. With horizontal tubes, use h_m from 200 to 400 Btu/(h · ft² · °F) for the following vapors condensing at atmospheric pressure: benzene, carbon tetrachloride, dichlormethane, dichlordifluoromethane, diphenyl ethyl alcohol, heptane, hexane, methyl alcohol, octane, toluene, and xylene. Ammonia gives h_m of 1,000, and mixtures of steam and organic vapors, forming immiscible condensates, give h_m ranging from 250 to 750, increasing with increasing proportion of steam. With film-type condensation of clean steam on horizontal tubes, h_m ranges from 1,000 to 3,000; see Eq. (4.4.13). With vertical tubes 10 to 20 ft long, ripples form in the film; values of h_m from Eq. (4.4.13a) should be increased 20 percent.

For long vertical tubes, $4\Gamma/\mu_f$ may exceed 2,100; in that case:

$$h_m(\mu_f^2/k_f^3\rho_f^2 g_L)^{1/3} = 0.0077(4\Gamma/\mu_f)^{0.4} \qquad (4.4.13b)$$

The presence of **noncondensible gas,** such as air, seriously reduces h, and consequently all vapor-heated apparatus should be well vented.

With steam, small traces of certain promoters (Nagle, U.S. Patent 1,995,361) such as oleic acid and benzyl mercaptan become adsorbed in a very thin layer on the surface of the tubes, preventing the condensate from wetting the metal and inducing dropwise condensation, which gives much higher values of h_m (7,000 to 70,000) than film-type condensation. However, with dirty or corroded surfaces, it is difficult to maintain dropwise condensation. Figure 4.4.4 shows overall coefficients U_o for condensing steam at 1 atm on a vertical 10-ft length of copper tube, ⅝ in OD, 0.049-in wall, at various water velocities.

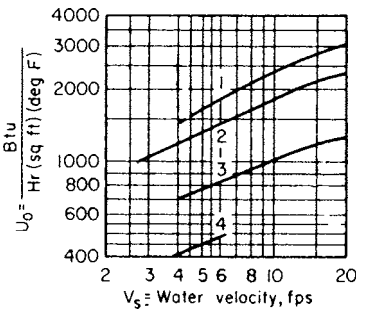

Fig. 4.4.4 Overall coefficients between condensing steam and water. Curve 1, chromium-plated copper, oleic acid; curve 2, copper, benzyl mercaptan; curve 3, copper, oleic acid; curve 4, admiralty metal, no promoter.

Boiling Liquids The nature of the heat transfer from a submerged heater to a pool of boiling water is shown in Fig. 4.4.5. Other liquids exhibit the same qualitative features. In the range *AB*, heat transfer to the liquid occurs solely by natural convection, and evaporation occurs at the free surface of the pool. In the range *BC*, **nucleate boiling** occurs. Bubbles form at active nuclei on the heating surface, detach, and rise to the pool surface. At point *C*, the heat flux passes through a maximum at

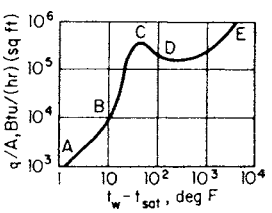

Fig. 4.4.5 Boiling of water at 212°F on a platinum surface.

a temperature difference called the **critical** Δt. In the range *CD,* transitional boiling occurs. At point *D*, the transition is complete and the heating surface is completely blanketed by a vapor film. This is the point of minimum heat flux, or the **Leidenfrost point.** In the range *DE*, the heating surface continues to be blanketed by a vapor film.

The range *AB* is adequately correlated by the usual natural-convection equations. No truly adequate correlation is available for the range *BC* because the complex processes of nucleation and interfacial interaction are only partially understood. However, the relation due to Rohsenow (*Trans. ASME,* **74,** 1952, pp. 969–976) is one of the best and can be reliably used for modest extrapolations of existing data.

$$\frac{C_{p,l}(t_w - t_{\text{sat}})}{\lambda} = C_{fs}\left[\frac{q/A}{\mu_l \lambda}\sqrt{\frac{g_c \sigma}{g_L(\rho_l - \rho_v)}}\right]^{1/3}\left(\frac{C_{p,l}\mu_l}{k_l}\right)^{1.7} \qquad (4.4.14a)$$

The value of the constant C_{fs} is intimately dependent on the nature of the particular fluid-solid pair and must be determined by experiment. It usually assumes values in the range $0.003 < C_{fs} < 0.05$ and is not affected by moderate subcooling or the shape of the heating surface.

Zuber (*USAEC Rep.* AECU-4439, June, 1959) has presented a theoretical equation for the maximum heat flux from a flat, horizontal surface. The analysis is based on considerations of hydrodynamic stability. For saturated liquids,

$$\left(\frac{q}{A}\right)_{\max} = K_1 \rho_v \lambda\left[\frac{\sigma g_L g_c(\rho_l - \rho_v)}{\rho_v^2}\right]^{1/4}\left(\frac{\rho_l}{\rho_l + \rho_v}\right)^{1/2} \qquad (4.4.14b)$$

$$0.12 < K_1 < 0.157 \qquad \text{(theoretical)}$$

Berenson (Sc.D. thesis, Mechanical Engineering Department, MIT, 1960) used a similar analysis and obtained a relation which is identical for $\rho_l \gg \rho_v$, but he found that $K_1 = 0.18$ gives better agreement with the data. The theoretical basis of this equation has been subject to attack, but the correlation appears to be the best available. Zuber also performed an analysis for subcooled liquids and proposed a modification which is also in excellent agreement with experiment:

$$\left(\frac{q}{A}\right)_{\max} = K_1 \rho_v[\lambda + C_{p,l}(t_{\text{sat}} - t_l)]\left[\frac{\sigma g_L g_c(\rho_l - \rho_v)}{\rho_v^2}\right]^{0.25} \times \left(\frac{\rho_l}{\rho_l + \rho_v}\right)^{1/2} \times \left\{1 + \frac{5.33(\rho_l C_{p,l} k_l)^{1/2}(t_{\text{sat}} - t_l)}{\rho_v[\lambda + C_{p,l}(t_{\text{sat}} - t_l)]}\left[\frac{g_L(\rho_l - \rho_v)\rho_v^2}{\sigma^3 g_c^3}\right]^{1/8}\right\} \qquad (4.4.14c)$$

Zuber's hydrodynamic analysis of the Leidenfrost point yields

$$(q/A)_{\min} = K_2 \lambda \rho_v\left[\frac{\sigma g_L g_c(\rho_l - \rho_v)}{\rho_l^2}\right]^{1/4}$$

$$0.144 < K_2 < 0.177 \qquad (4.4.14d)$$

Berenson finds better agreement with the data if $K_2 = 0.09$. For very small wires, the heat flux will exceed that predicted by this flat-plate formula. A reliable prediction of the critical temperature is not available.

For nucleate boiling accompanied by forced convection, the heat flux may be approximated by the sum of the heat flux for pool boiling alone and the heat flux for forced convection alone. This procedure will not be satisfactory at high qualities, and no satisfactory correlation exists for the maximum heat flux.

For a given liquid and system pressure, the nature of the surface may substantially influence the flux at a given (Δt), Table 4.4.11. These data may be used as rough approximations for a bank of submerged tubes. Film coefficients for scale deposits are given in Table 4.4.9.

For **forced-circulation evaporators,** vapor binding is also encountered. Thus with liquid benzene entering a 4-pass steam-jacketed pipe at 0.9 ft/s, up to the point where 60 percent by weight was vaporized, the maximum flux of 60,000 Btu/h · ft^2 was obtained at an overall temperature difference of 60°F; beyond this point, the coefficient and flux decreased rapidly, approaching the values obtained in superheating vapor, see Eq. (4.4.6b). For comparison, in a natural convection evaporator, a maximum flux of 73,000 Btu/h · ft^2 was obtained at $(\Delta t)_v$ of 100°F.

Combined Convection and Radiation Coefficients In some cases of heat loss, such as that from bare and insulated pipes, where loss is by convection to the air and radiation to the walls of the enclosing space, it is convenient to use a combined convection and radiation coefficient $h_c + h_r$. The rate of heat loss thus becomes

$$q = (h_c + h_r)A(\Delta t)_s \qquad (4.4.15)$$

where $(\Delta t)_s$ is the temperature difference, °F, between the surface of the hot body and the walls of the space. In evaluating $(h_c + h_r)$, h_c should be calculated by the appropriate convection formula [see Eqs. (4.4.11c) to (4.4.11g)] and h_r from the equation

$$h_r = 0.00685\varepsilon(T_{\text{av}}/100)^3$$

where ε is the emissivity of the radiating surface (see Sec. 4.3). T_{av} is the average temperature of the surface and the enclosing walls, °R. For oxidized bare steel pipe, the sum $h_c + h_r$ may be taken directly from Table 4.4.12.

Table 4.4.12 Values of $h_c + h_r$

Heat Transmission through Pipe Insulation (McMillan, *Trans. ASME,* 1915) For any number of layers of insulation on any size of pipe, Eqs. (4.4.2), (4.4.4), and (4.4.15) combine to give

$$\frac{q_o}{A_o} = \frac{(\Delta t)_o}{\frac{r_o}{k_1}\ln\frac{r_2}{r_1} + \frac{r_o}{k_2}\ln\frac{r_3}{r_2} + \cdots + \frac{1}{h_c + h_r}} \tag{4.4.16}$$

where q_o/A_o is the Btu/(h · ft^2) of outer surface of the last layer; $(\Delta t)_o$ is the overall temperature difference (°F) between pipe and air; r_o is the radius, feet, of the outer surface; r_1 is the outside radius (ft) of the pipe, $r_2 = r_1 +$ thickness of first layer of insulation, foot; $r_3 = r_2$ plus the thickness of second layer, etc.; and k_1, k_2, k_3, etc., are the conductivities of the respective layers. For average indoor conditions, $h_c + h_r$ is often taken as 2 as an approximation, since a substantial error in $h_c + h_r$ will have but little effect on the overall loss of heat. Figure 4.4.6 shows the variation in U_o with pipe size and thickness of insulation (for $k = 0.042$) for pipe and air temperatures of 375 and 75°F, respectively.

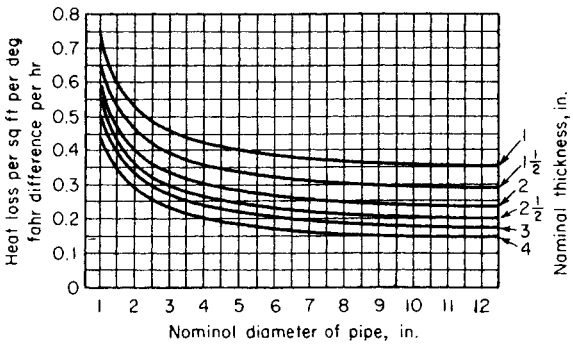

Fig. 4.4.6 Variation with pipe size of overall coefficient U_o for a given thickness of insulation, for $k = 0.042$.

STRESS-STRAIN DIAGRAMS

The Stress-Strain Curve The engineering tensile stress-strain curve is obtained by **static loading** of a standard specimen, that is, by applying the load slowly enough that all parts of the specimen are in equilibrium at any instant. The curve is usually obtained by controlling the loading rate in the tensile machine. ASTM Standards require a loading rate not exceeding 100,000 lb/in^2 (70 kgf/mm^2)/min. An alternate method of obtaining the curve is to specify the strain rate as the independent variable, in which case the loading rate is continuously adjusted to maintain the required strain rate. A strain rate of 0.05 in/in/(min) is commonly used. It is measured usually by an extensometer attached to the gage length of the specimen. Figure 5.1.1 shows several stress-strain curves.

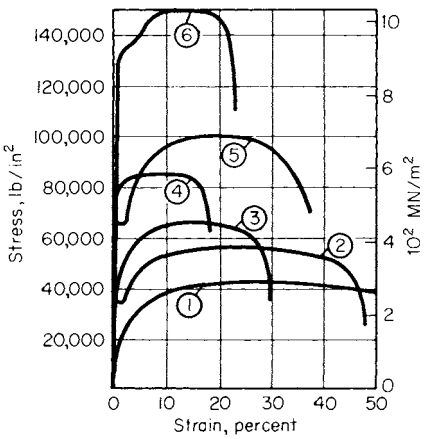

Fig. 5.1.1 Comparative stress-strain diagrams. (1) Soft brass; (2) low carbon steel; (3) hard bronze; (4) cold rolled steel; (5) medium carbon steel, annealed; (6) medium carbon steel, heat treated.

For most engineering materials, the curve will have an initial linear elastic region (Fig. 5.1.2) in which deformation is reversible and time-independent. The slope in this region is **Young's modulus** E. The **proportional elastic limit** (PEL) is the point where the curve starts to deviate from a straight line. The **elastic limit** (frequently indistinguishable from PEL) is the point on the curve beyond which plastic deformation is present after release of the load. If the stress is increased further, the stress-strain curve departs more and more from the straight line. Unloading the specimen at point X (Fig. 5.1.2), the portion XX' is linear and is essentially parallel to the original line OX''. The horizontal distance OX' is called the **permanent set** corresponding to the stress at X. This is the basis for the construction of the arbitrary **yield strength.** To determine the yield strength, a straight line XX' is drawn parallel to the initial elastic line OX'' but displaced from it by an arbitrary value of permanent strain. The permanent strain commonly used is 0.20 percent of the original gage length. The intersection of this line with the curve determines the stress value called the yield strength. In reporting the yield strength, the amount of permanent set should be specified. The arbitrary yield strength is used especially for those materials not exhibiting a natural yield point such as nonferrous metals; but it is not limited to these. Plastic behavior is somewhat time-dependent, particularly at high temperatures. Also at high temperatures, a small amount of time-dependent reversible strain may be detectable, indicative of **anelastic** behavior.

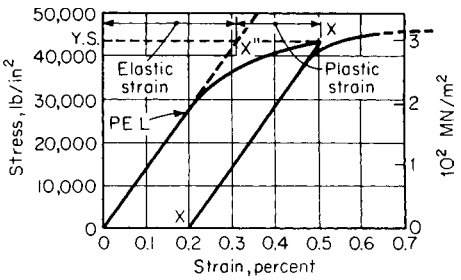

Fig. 5.1.2 General stress-strain diagram.

The **ultimate tensile strength** (UTS) is the maximum load sustained by the specimen divided by the original specimen cross-sectional area. The percent **elongation at failure** is the plastic extension of the specimen at failure expressed as (the change in original gage length × 100) divided by the original gage length. This extension is the sum of the **uniform** and **nonuniform** elongations. The uniform elongation is that which occurs prior to the UTS. It has an unequivocal significance, being associated with uniaxial stress, whereas the nonuniform elongation which occurs during localized extension (necking) is associated with triaxial stress. The nonuniform elongation will depend on geometry, particularly the ratio of specimen gage length L_0 to diameter D or square root of cross-sectional area A. ASTM Standards specify test-specimen geometry for a number of specimen sizes. The ratio $L_0/\sqrt{A}$ is maintained at 4.5 for flat- and round-cross-section specimens. The original gage length should always be stated in reporting elongation values.

The specimen percent **reduction in area** (RA) is the contraction in cross-sectional area at the fracture expressed as a percentage of the original area. It is obtained by measurement of the cross section of the broken specimen at the fracture location. The RA along with the load at fracture can be used to obtain the **fracture stress,** that is, fracture load divided by cross-sectional area at the fracture. See Table 5.1.1.

The type of fracture in tension gives some indications of the quality of the material, but this is considerably affected by the testing temperature, speed of testing, the shape and size of the test piece, and other conditions. Contraction is greatest in tough and ductile materials and least in brittle materials. In general, fractures are either of the **shear** or of the **separation** (loss of cohesion) type. Flat tensile specimens of ductile metals often show shear failures if the ratio of width to thickness is greater than 6:1. A completely shear-type failure may terminate in a chisel edge, for a flat specimen, or a point rupture, for a round specimen. Separation failures occur in brittle materials, such as certain cast irons. Combinations of both shear and separation failures are common on round specimens of ductile metal. Failure often starts at the axis in a necked region and produces a relatively flat area which grows until the material shears along a cone-shaped surface at the outside of the specimen, resulting in what is known as the cup-and-cone fracture.

Table 5.1.1 Typical Mechanical Properties at Room Temperature
(Based on ordinary stress-strain values)

Metal	Tensile strength, 1,000 lb/in^2	Yield strength, 1,000 lb/in^2	Ultimate elongation, %	Reduction of area, %	Brinell no.

NOTE: Compressive strength of cast iron, 80,000 to 150,000 lb/in^2.
Compressive yield strength of all metals, except those cold-worked = tensile yield strength.
Stress 1,000 lb/in^2 × 6.894 = stress, MN/m^2.

Double cup-and-cone and rosette fractures sometimes occur. Several types of tensile fractures are shown in Fig. 5.1.3.

Annealed or hot-rolled mild steels generally exhibit a **yield point** (see Fig. 5.1.4). Here, in a constant strain-rate test, a large increment of extension occurs under constant load at the elastic limit or at a stress just below the elastic limit. In the latter event the stress drops suddenly from the **upper yield point** to the **lower yield point.** Subsequent to the drop, the yield-point extension occurs at constant stress, followed by a rise to the UTS. Plastic flow during the yield-point extension is discontinuous;

Fig. 5.1.3 Typical metal fractures in tension.

successive zones of plastic deformation, known as **Luder's bands** or **stretcher strains,** appear until the entire specimen gage length has been uniformly deformed at the end of the yield-point extension. This behavior causes a banded or stepped appearance on the metal surface. The exact form of the stress-strain curve for this class of material is sensitive to test temperature, test strain rate, and the characteristics of the tensile machine employed.

The plastic behavior in a uniaxial tensile test can be represented as the **true stress-strain curve.** The **true stress** σ is based on the instantaneous

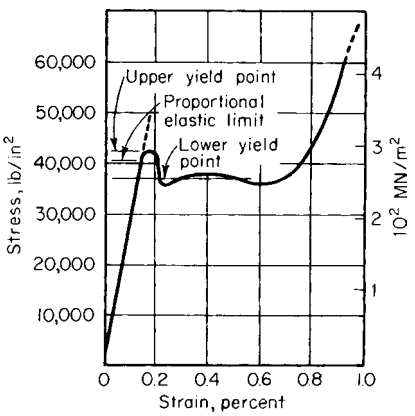

Fig. 5.1.4 Yielding of annealed steel.

cross section A, so that σ = load/A. The instantaneous **true strain** increment is $-dA/A$, or dL/L prior to necking. Total true strain ε is

$$\int_{A_0}^{A} -\frac{dA}{A} = \ln\left(\frac{A_0}{A}\right)$$

or $\ln (L/L_0)$ prior to necking. The true stress-strain curve or flow curve obtained has the typical form shown in Fig. 5.1.5. In the part of the test subsequent to the maximum load point (UTS), when necking occurs, the true strain of interest is that which occurs in an infinitesimal length at the region of minimum cross section. True strain for this element can still be expressed as $\ln (A_0/A)$, where A refers to the minimum cross section. Methods of constructing the true stress-strain curve are described in the technical literature. In the range between initial yielding and the neighborhood of the maximum load point the relationship between plastic strain ε_p and true stress often approximates

$$\sigma = k\varepsilon_p^n$$

where k is the **strength coefficient** and n is the **work-hardening exponent.** For a material which shows a yield point the relationship applies only to the rising part of the curve beyond the lower yield. It can be shown that at the maximum load point the slope of the true stress-strain curve equals the true stress, from which it can be deduced that for a material obeying the above exponential relationship between ε_p and n, $\varepsilon_p = n$ at the maximum load point. The exponent strongly influences the spread between YS and UTS on the engineering stress-strain curve. Values of n and k for some materials are shown in Table 5.1.2. A point on the flow curve indentifies the **flow stress** corresponding to a certain strain, that is, the stress required to bring about this amount of plastic deformation. The concept of true strain is useful for accurately describing large amounts of plastic deformation. The linear strain definition $(L - L_0)/L_0$ fails to correct for the continuously changing gage length, which leads to an increasing error as deformation proceeds.

During extension of a specimen under tension, the change in the specimen cross-sectional area is related to the elongation by **Poisson's ratio** μ, which is the ratio of strain in a transverse direction to that in the longitudinal direction. Values of μ for the elastic region are shown in Table 5.1.3. For plastic strain it is approximately 0.5.

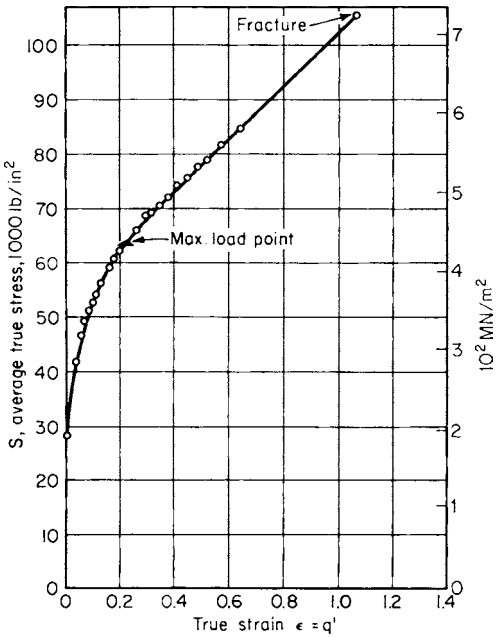

Fig. 5.1.5 True stress-strain curve for 20°C annealed mild steel.

Table 5.1.2 Room-Temperature Plastic-Flow Constants for a Number of Metals

Material	Condition	k, 1,000 in² (MN/m²)	n
0.40% C steel	Quenched and tempered at 400°F (478K)	416 (2,860)	0.088
0.05% C steel	Annealed and temper-rolled	72 (49.6)	0.235
2024 aluminum	Precipitation-hardened	100 (689)	0.16
2024 aluminum	Annealed	49 (338)	0.21
Copper	Annealed	46.4 (319)	0.54

Zirconium, crystal bar	11–14			
Molybdenum, arc-cast	48–52			

The general effect of increased strain rate is to increase the resistance to plastic deformation and thus to raise the flow curve. Decreasing test temperature also raises the flow curve. The effect of strain rate is expressed as **strain-rate sensitivity** m. Its value can be measured in the tension test if the strain rate is suddenly increased by a small increment during the plastic extension. The flow stress will then jump to a higher value. The strain-rate sensitivity is the ratio of incremental changes of $\log \sigma$ and $\log \dot{\varepsilon}$

$$m = \left(\frac{\delta \log \sigma}{\delta \log \dot{\varepsilon}} \right)_{\varepsilon}$$

For most engineering materials at room temperature the strain rate sensitivity is of the order of 0.01. The effect becomes more significant at elevated temperatures, with values ranging to 0.2 and sometimes higher.

Compression Testing The compressive stress-strain curve is similar to the tensile stress-strain curve up to the yield strength. Thereafter, the progressively increasing specimen cross section causes the compressive stress-strain curve to diverge from the tensile curve. Some ductile metals will not fail in the compression test. Complex behavior occurs when the direction of stressing is changed, because of the **Bauschinger effect,** which can be described as follows: If a specimen is first plastically strained in tension, its yield stress in compression is reduced and vice versa.

Combined Stresses This refers to the situation in which stresses are present on each of the faces of a cubic element of the material. For a given cube orientation the applied stresses may include shear stresses over the cube faces as well as stresses normal to them. By a suitable rotation of axes the problem can be simplified: applied stresses on the new cubic element are equivalent to three mutually orthogonal **principal stresses** σ_1, σ_2, σ_3 alone, each acting normal to a cube face. Combined stress behavior in the elastic range is described in Sec. 5.2, Mechanics of Materials.

Prediction of the conditions under which plastic yielding will occur under combined stresses can be made with the help of several empirical theories. In the **maximum-shear-stress theory** the criterion for yielding is that yielding will occur when

$$\sigma_1 - \sigma_3 = \sigma_{ys}$$

in which σ_1 and σ_3 are the largest and smallest principal stresses, respectively, and σ_{ys} is the uniaxial tensile yield strength. This is the simplest theory for predicting yielding under combined stresses. A more accurate prediction can be made by the **distortion-energy theory,** according to which the criterion is

$$(\sigma_1 - \sigma_2)^2 + (\sigma_1 - \sigma_3)^2 + (\sigma_2 - \sigma_3)^2 = 2(\sigma_{ys})^2$$

Stress-strain curves in the plastic region for combined stress loading can be constructed. However, a particular stress state does not determine a unique strain value. The latter will depend on the stress-state path which is followed.

Plane strain is a condition where strain is confined to two dimensions. There is generally stress in the third direction, but because of mechanical constraints, strain in this dimension is prevented. Plane strain occurs in certain metalworking operations. It can also occur in the neighborhood of a crack tip in a tensile loaded member if the member is sufficiently thick. The material at the crack tip is then in triaxial tension, which condition promotes brittle fracture. On the other hand, ductility is enhanced and fracture is suppressed by triaxial compression.

Stress Concentration In a structure or machine part having a notch or any abrupt change in cross section, the maximum stress will occur at this location and will be greater than the stress calculated by elementary formulas based upon simplified assumptions as to the stress distribution. The ratio of this maximum stress to the nominal stress (calculated by the elementary formulas) is the **stress-concentration factor** K_t. This is a constant for the particular geometry and is independent of the material, provided it is isotropic. The stress-concentration factor may be determined experimentally or, in some cases, theoretically from the mathematical theory of elasticity. The factors shown in Figs. 5.1.6 to 5.1.13 were determined from both photoelastic tests and the theory of

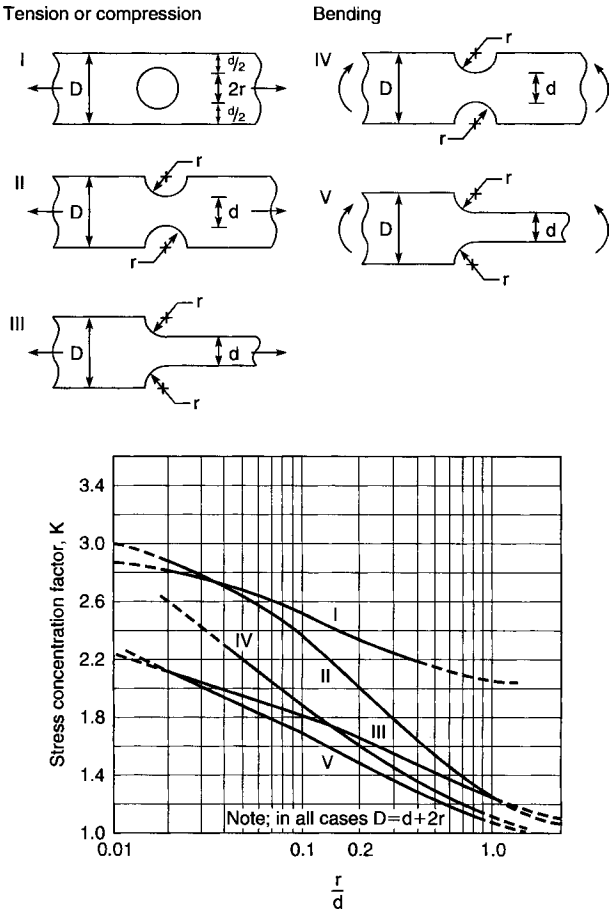

Fig. 5.1.6 Flat plate with semicircular fillets and grooves or with holes. I, II, and III are in tension or compression; IV and V are in bending.

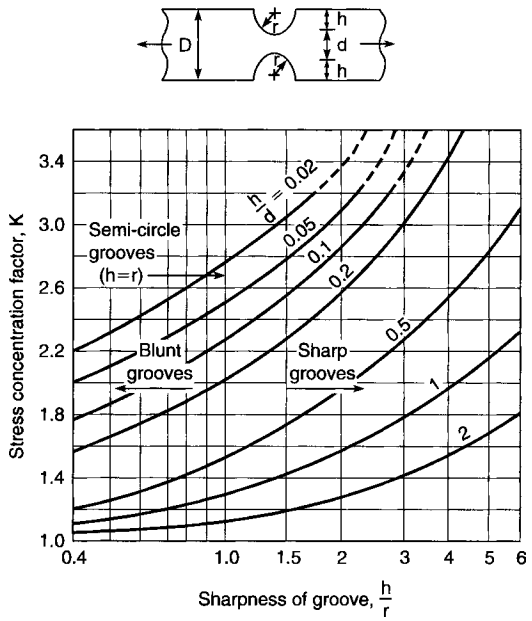

Fig. 5.1.7 Flat plate with grooves, in tension.

elasticity. Stress concentration will cause failure of brittle materials if the concentrated stress is larger than the ultimate strength of the material. In ductile materials, concentrated stresses higher than the yield strength will generally cause local plastic deformation and redistribution of stresses (rendering them more uniform). On the other hand, even with ductile materials areas of stress concentration are possible sites for fatigue if the component is cyclically loaded.

FRACTURE AT LOW STRESSES

Materials under tension sometimes fail by rapid fracture at stresses much below their strength level as determined in tests on carefully prepared specimens. These **brittle, unstable,** or **catastrophic failures** originate at preexisting stress-concentrating flaws which may be inherent in a material.

The transition-temperature approach is often used to ensure fracture-safe design in structural-grade steels. These materials exhibit a characteristic temperature, known as the **ductile brittle transition** (DBT) temperature, below which they are susceptible to brittle fracture. The transition-temperature approach to fracture-safe design ensures that the transition temperature of a material selected for a particular application is suitably matched to its intended use temperature. The DBT can be detected by plotting certain measurements from tensile or impact tests against temperature. Usually the transition to brittle behavior is complex, being neither fully ductile nor fully brittle. The range may extend over 200°F (110 K) interval. The **nil-ductility temperature** (NDT), determined by the **drop weight test** (see ASTM Standards), is an important reference point in the transition range. When NDT for a particular steel is known, temperature-stress combinations can be specified which define the limiting conditions under which catastrophic fracture can occur.

In the **Charpy V-notch** (CVN) impact test, a notched-bar specimen (Fig. 5.1.26) is used which is loaded in bending (see ASTM Standards). The energy absorbed from a swinging pendulum in fracturing the specimen is measured. The pendulum strikes the specimen at 16 to 19 ft (4.88 to 5.80 m)/s so that the specimen deformation associated with fracture occurs at a rapid strain rate. This ensures a conservative measure of toughness, since in some materials, toughness is reduced by high strain rates. A CVN impact energy vs. temperature curve is shown in Fig. 5.1.14, which also shows the transitions as given by percent brittle fracture and by percent lateral expansion. The CVN energy has no analytical significance. The test is useful mainly as a guide to the fracture behavior of a material for which an empirical correlation has been established between impact energy and some rigorous fracture criterion. For a particular grade of steel the CVN curve can be correlated with NDT. (See ASME Boiler and Pressure Vessel Code.)

Fracture Mechanics This analytical method is used for ultra-high-strength alloys, transition-temperature materials below the DBT temperature, and some low-strength materials in heavy section thickness.

Fracture mechanics theory deals with crack extension where plastic effects are negligible or confined to a small region around the crack tip. The present discussion is concerned with a through-thickness crack in a tension-loaded plate (Fig. 5.1.15) which is large enough so that the crack-tip stress field is not affected by the plate edges. Fracture mechanics theory states that unstable crack extension occurs when the work required for an increment of crack extension, namely, surface energy and energy consumed in local plastic deformation, is exceeded by the elastic-strain energy released at the crack tip. The elastic-stress field

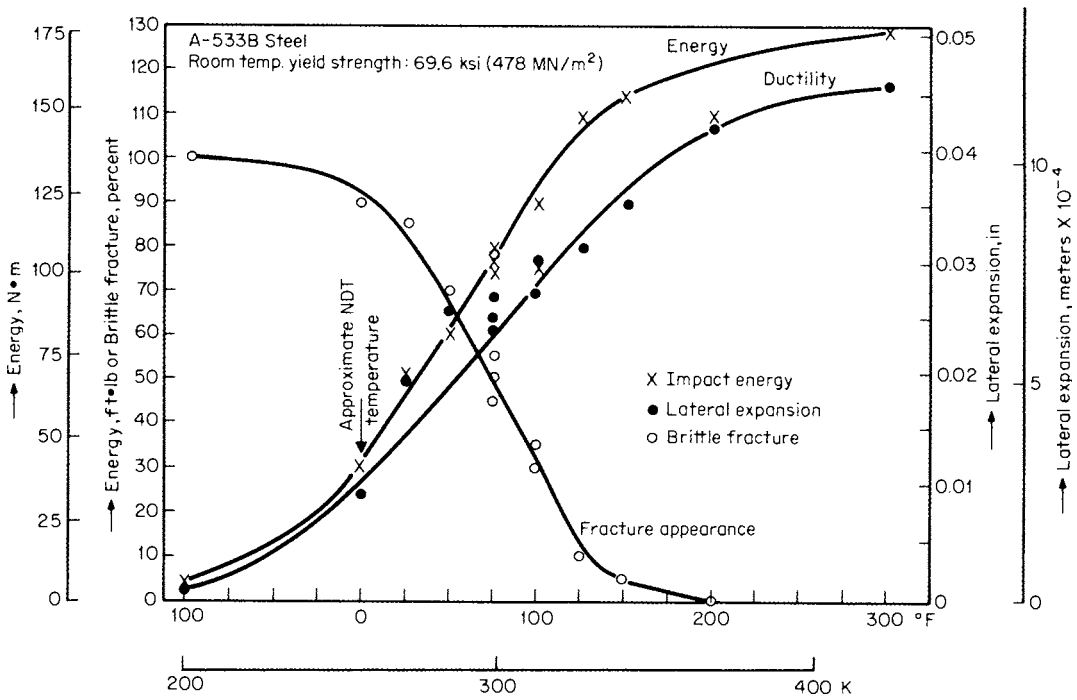

Fig. 5.1.14 CVN transition curves. (*Data from Westinghouse R & D Lab.*)

surrounding one of the crack tips in Fig. 5.1.15 is characterized by the **stress intensity** K_I, which has units of $(\text{lb}\sqrt{\text{in}})/\text{in}^2$ or $(\text{N}/\sqrt{\text{m}})/\text{m}^2$. It is a function of applied nominal stress σ, crack half-length a, and a geometry factor Q:

$$K_I^2 = Q\sigma^2\pi a \tag{5.1.1}$$

for the situation of Fig. 5.1.15. For a particular material it is found that as K_I is increased, a value K_c is reached at which unstable crack

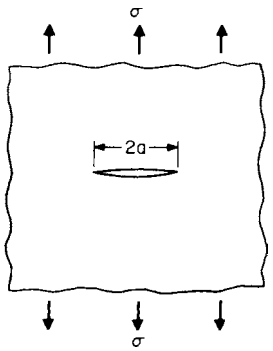

Fig. 5.1.15 Through-thickness crack geometry.

propagation occurs. K_c depends on plate thickness B, as shown in Fig. 5.1.16. It attains a constant value when B is great enough to provide plane-strain conditions at the crack tip. The low plateau value of K_c is an important material property known as the **plane-strain critical stress intensity** or **fracture toughness** K_{Ic}. Values for a number of materials are shown in Table 5.1.4. They are influenced strongly by processing and small changes in composition, so that the values shown are not necessarily typical. K_{Ic} can be used in the critical form of Eq. (5.1.1):

$$(K_{Ic})^2 = Q\sigma^2\pi a_{cr} \tag{5.1.2}$$

to predict failure stress when a maximum flaw size in the material is known or to determine maximum allowable flaw size when the stress is set. The predictions will be accurate so long as plate thickness B satisfies the **plane-strain criterion:** $B \geq 2.5(K_{Ic}/\sigma_{ys})^2$. They will be conservative if a plane-strain condition does not exist. A big advantage of the fracture mechanics approach is that stress intensity can be calculated by

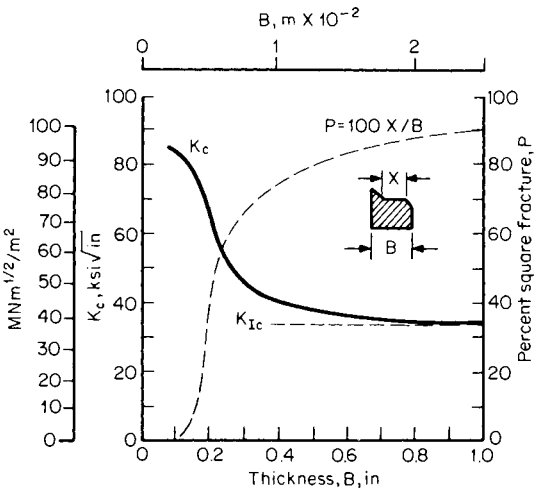

Fig. 5.1.16 Dependence of K_c and fracture appearance (in terms of percentage of square fracture) on thickness of plate specimens. Based on data for aluminum 7075-T6. (*From Scrawly and Brown, STP-381, ASTM.*)

Table 5.1.4 Room-Temperature K_{Ic} Values on High-Strength Materials*

Material	0.2% YS, 1,000 in² (MN/m²)	K_{Ic}, 1,000 in² $\sqrt{\text{in}}$ (MN m$^{1/2}$/m²)
18% Ni maraging steel	300 (2,060)	46 (50.7)
18% Ni maraging steel	270 (1,850)	71 (78)
18% Ni maraging steel	198 (1,360)	87 (96)
Titanium 6-4 alloy	152 (1,022)	39 (43)
Titanium 6-4 alloy	140 (960)	75 (82.5)

equations analogous to (5.1.1) for a wide variety of geometries, types of crack, and loadings (Paris and Sih, "Stress Analysis of Cracks," STP-381, ASTM, 1965). Failure occurs in all cases when K_I reaches K_{Ic}. Fracture mechanics also provides a framework for predicting the occurrence of **stress-corrosion cracking** by using Eq. (5.1.2) with K_{Ic} replaced by K_{Iscc}, which is the material parameter denoting resistance to stress-corrosion-crack propagation in a particular medium.

Two standard test specimens for K_{Ic} determination are specified in ASTM standards, which also detail specimen preparation and test procedure. Recent developments in fracture mechanics permit treatment of crack propagation in the ductile regime. (See "Elastic-Plastic Fracture," ASTM.)

FATIGUE

Fatigue is generally understood as the gradual deterioration of a material which is subjected to repeated loads. In fatigue testing, a specimen is subjected to periodically varying constant-amplitude stresses by means of mechanical or magnetic devices. The applied stresses may alternate between equal positive and negative values, from zero to maximum positive or negative values, or between unequal positive and negative values. The most common loading is alternate tension and compression of equal numerical values obtained by rotating a smooth cylindrical specimen while under a bending load. A series of fatigue tests are made on a number of specimens of the material at different stress levels. The stress endured is then plotted against the number of cycles sustained. By choosing lower and lower stresses, a value may be found which will not produce failure, regardless of the number of applied cycles. This stress value is called the **fatigue limit.** The diagram is called the stress-cycle diagram or ***S-N* diagram.** Instead of recording the data on cartesian coordinates, either stress is plotted vs. the logarithm of the number of cycles (Fig. 5.1.17) or both stress and cycles are plotted to logarithmic scales. Both diagrams show a relatively sharp bend in the curve near the fatigue limit for ferrous metals. The fatigue limit may be established for most steels between 2 and 10 million cycles. Nonferrous metals usually show no clearly defined fatigue limit. The *S-N* curves in these cases indicate a continuous decrease in stress values to several hundred million cycles, and both the stress value and the number of cycles sustained should be reported. See Table 5.1.5.

The mean stress (the average of the maximum and minimum stress values for a cycle) has a pronounced influence on the stress range (the algebraic difference between the maximum and minimum stress values). Several empirical formulas and graphical methods such as the "modified Goodman diagram" have been developed to show the influence of the mean stress on the stress range for failure. A simple but conservative approach (see Soderberg, Working Stresses, *Jour. Appl. Mech.,* **2,** Sept. 1935) is to plot the variable stress S_v (one-half the stress range) as ordinate vs. the mean stress S_m as abscissa (Fig. 5.1.18). At zero mean stress, the ordinate is the fatigue limit under completely reversed stress. Yielding will occur if the mean stress exceeds the yield stress S_o, and this establishes the extreme right-hand point of the diagram. A straight line is drawn between these two points. The coordinates of any other point along this line are values of S_m and S_v which may produce failure.

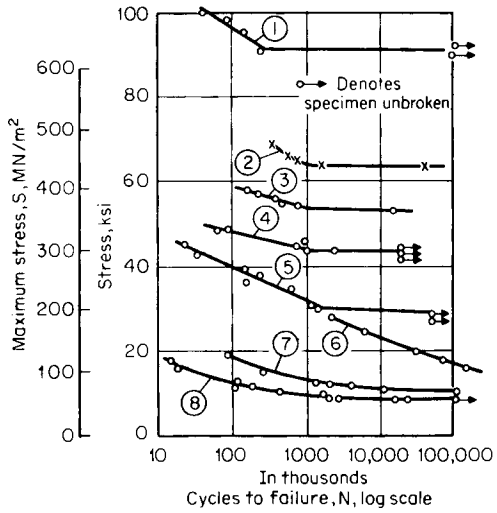

Fig. 5.1.17 The *S-N* diagrams from fatigue tests. (1) 1.20% C steel, quenched and drawn at 860°F (460°C); (2) alloy structural steel; (3) SAE 1050, quenched and drawn at 1,200°F (649°C); (4) SAE 4130, normalized and annealed; (5) ordinary structural steel; (6) Duralumin; (7) copper, annealed; (8) cast iron (reversed bending).

Surface defects, such as roughness or scratches, and notches or shoulders all reduce the fatigue strength of a part. With a notch of prescribed geometric form and known concentration factor, the reduction in strength is appreciably less than would be called for by the concentration factor itself, but the various metals differ widely in their susceptibility to the effect of roughness and concentrations, or **notch sensitivity.**

For a given material subjected to a prescribed state of stress and type of loading, notch sensitivity can be viewed as the ability of that material to resist the concentration of stress incidental to the presence of a notch. Alternately, notch sensitivity can be taken as a measure of the degree to which the geometric stress concentration factor is reduced. An attempt is made to rationalize notch sensitivity through the equation $q = (K_f - 1)/(K - 1)$, where q is the notch sensitivity, K is the geometric stress concentration factor (from data similar to those in Figs. 5.1.5 to 5.1.13 and the like), and K_f is defined as the ratio of the strength of unnotched material to the strength of notched material. Ratio K_f is obtained from laboratory tests, and K is deduced either theoretically or from laboratory tests, but both must reflect the same state of stress and type of loading. The value of q lies between 0 and 1, so that (1) if $q = 0$, $K_f = 1$ and the material is not notch-sensitive (soft metals such as copper, aluminum, and annealed low-strength steel); (2) if $q = 1$, $K_f = K$, the material is fully notch-sensitive and the full value of the geometric stress concentration factor is not diminished (hard, high-strength steel). In practice, q will lie somewhere between 0 and 1, but it may be hard to quantify. Accordingly, the pragmatic approach to arrive at a solution to a design problem often takes a conservative route and sets $q = 1$. The exact material properties at play which are responsible for notch sensitivity are not clear.

Further, notch sensitivity seems to be higher, and ordinary fatigue strength lower in large specimens, necessitating full-scale tests in many cases (see Peterson, Stress Concentration Phenomena in Fatigue of Metals, *Trans. ASME,* **55,** 1933, p. 157, and Buckwalter and Horger, Investigation of Fatigue Strength of Axles, Press Fits, Surface Rolling and Effect of Size, *Trans. ASM,* **25,** Mar. 1937, p. 229). **Corrosion** and **galling** (due to rubbing of mating surfaces) cause great reduction of fatigue strengths, sometimes amounting to as much as 90 percent of the original endurance limit. Although any corroding agent will promote severe corrosion fatigue, there is so much difference between the effects of "sea water" or "tap water" from different localities that numerical values are not quoted here.

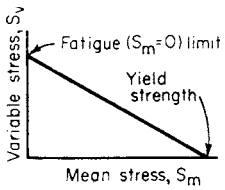

Fig. 5.1.18 Effect of mean stress on the variable stress for failure.

Overstressing specimens above the fatigue limit for periods shorter than necessary to produce failure at that stress reduces the fatigue limit in a subsequent test. Similarly, **understressing** below the fatigue limit may increase it. Shot peening, nitriding, and cold work usually improve fatigue properties.

No very good overall correlation exists between fatigue properties and any other mechanical property of a material. The best correlation is between the fatigue limit under completely reversed bending stress and the ordinary tensile strength. For many ferrous metals, the fatigue limit is approximately 0.40 to 0.60 times the tensile strength if the latter is below 200,000 lb/in^2. Low-alloy high-yield-strength steels often show higher values than this. The fatigue limit for nonferrous metals is approximately to 0.20 to 0.50 times the tensile strength. The fatigue limit in reversed shear is approximately 0.57 times that in reversed bending.

In some very important engineering situations components are cyclically stressed into the plastic range. Examples are thermal strains resulting from temperature oscillations and notched regions subjected to secondary stresses. Fatigue life in the plastic or **"low-cycle" fatigue** range has been found to be a function of plastic strain, and low-cycle fatigue testing is done with strain as the controlled variable rather than stress. Fatigue life N and cyclic plastic strain ε_p tend to follow the relationship

$$N\varepsilon_p^2 = C$$

where C is a constant for a material when $N < 10^5$. (See Coffin, A Study of Cyclic-Thermal Stresses in a Ductile Material, *Trans. ASME,* **76,** 1954, p. 947.)

Table 5.1.5 Typical Approximate Fatigue Limits for Reversed Bending

Metal	Tensile strength, 1,000 lb/in^2	Fatigue limit, 1,000 lb/in^2	Metal	Tensile strength, 1,000 lb/in^2	Fatigue limit, 1,000 lb/in^2
Cast iron	20–50	6–18	Copper	32–50	12–17
Malleable iron	50	24	Monel	70–120	20–50
Cast steel	60–80	24–32	Phosphor bronze	55	12
Armco iron	44	24	Tobin bronze, hard	65	21

Brasses, various	25–75	7–20	Molybdenum, as cast	98	45
Zirconium crystal bar	52	16–18	Titanium (Ti-75A)	91	45

NOTE: Stress, 1,000 lb/in^2 × 6.894 = stress, MN/m^2.

The type of physical change occurring inside a material as it is repeatedly loaded to failure varies as the life is consumed, and a number of stages in fatigue can be distinguished on this basis. The early stages comprise the events causing **nucleation of a crack** or flaw. This is most likely to appear on the surface of the material; **fatigue failures** generally originate at a surface. Following nucleation of the crack, it grows during the **crack-propagation** stage. Eventually the crack becomes large enough for some rapid terminal mode of failure to take over such as ductile rupture or brittle fracture. The rate of crack growth in the crack-propagation stage can be accurately quantified by fracture mechanics methods. Assuming an initial flaw and a loading situation as shown in Fig. 5.1.15, the rate of crack growth per cycle can generally be expressed as

$$da/dN = C_0(\Delta K_I)^n \tag{5.1.3}$$

where C_0 and n are constants for a particular material and ΔK_I is the range of stress intensity per cycle. K_I is given by (5.1.1). Using (5.1.3), it is possible to predict the number of cycles for the crack to grow to a size at which some other mode of failure can take over. Values of the constants C_0 and n are determined from specimens of the same type as those used for determination of K_{Ic} but are instrumented for accurate measurement of slow crack growth.

Constant-amplitude fatigue-test data are relevant to many rotary-machinery situations where constant cyclic loads are encountered. There are important situations where the component undergoes variable loads and where it may be advisable to use **random-load testing.** In this method, the load spectrum which the component will experience in service is determined and is applied to the test specimen artificially.

CREEP

Experience has shown that, for the design of equipment subjected to sustained loading at elevated temperatures, little reliance can be placed on the usual short-time tensile properties of metals at those temperatures. Under the application of a constant load it has been found that materials, both metallic and nonmetallic, show a gradual flow or **creep** even for stresses below the proportional limit at elevated temperatures. Similar effects are present in low-melting metals such as lead at room temperature. The deformation which can be permitted in the satisfactory operation of most high-temperature equipment is limited.

In metals, creep is a plastic deformation caused by slip occurring along crystallographic directions in the individual crystals, together with some flow of the grain-boundary material. After complete release of load, a small fraction of this plastic deformation is recovered with time. Most of the flow is nonrecoverable for metals.

Since the early creep experiments, many different types of tests have come into use. The most common are the **long-time creep test** under constant tensile load and the **stress-rupture test.** Other special forms are the **stress-relaxation test** and the **constant-strain-rate test.**

The **long-time creep test** is conducted by applying a dead weight to one end of a lever system, the other end being attached to the specimen surrounded by a furnace and held at constant temperature. The axial deformation is read periodically throughout the test and a curve is plotted of the strain ε_0 as a function of time t (Fig. 5.1.19). This is repeated for various loads at the same testing temperature. The portion of the curve OA in Fig. 5.1.19 is the region of **primary creep,** AB the region of **secondary creep,** and BC that of **tertiary creep.** The strain rates, or the slopes of the curve, are decreasing, constant, and increasing, respectively, in these three regions. Since the period of the creep test is usually much shorter than the duration of the part in service, various extrapolation procedures are followed (see Gittus, "Creep, Viscoelasticity and Creep Fracture in Solids," Wiley, 1975). See Table 5.1.6.

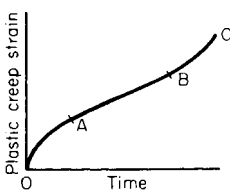

Fig. 5.1.19 Typical creep curve.

In practical applications the region of constant-strain rate (secondary creep) is often used to estimate the probable deformation throughout the life of the part. It is thus assumed that this rate will remain constant during periods beyond the range of the test data. The working stress is chosen so that this total deformation will not be excessive. An **arbitrary creep strength,** which is defined as the stress which at a given temperature will result in 1 percent deformation in 100,000 h, has received a certain amount of recognition, but it is advisable to determine the proper stress for each individual case from diagrams of stress vs. creep rate (Fig. 5.1.20) (see "Creep Data," ASTM and ASME).

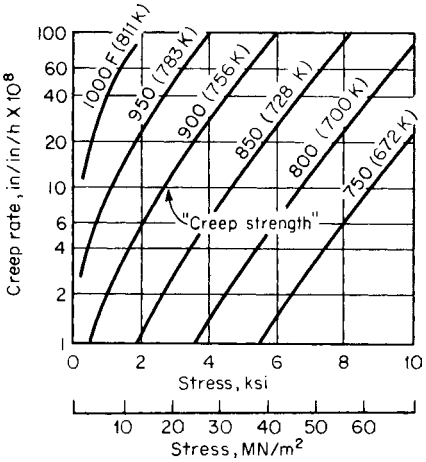

Fig. 5.1.20 Creep rates for 0.35% C steel.

Additional temperatures (°F) and stresses (in 1,000 lb/in^2) for stated creep rates (percent per 1,000 h) for wrought nonferrous metals are as follows:

60-40 Brass: Rate 0.1, temp. 350 (400), stress 8 (2); rate 0.01, temp 300 (350) [400], stress 10 (3) [1].

Phosphor bronze: Rate 0.1, temp 400 (550) [700] [800], stress 15 (6) [4] [4]; rate 0.01, temp 400 (550) [700], stress 8 (4) [2].

Nickel: Rate 0.1, temp 800 (1000), stress 20 (10).

70 Cu, 30 NI. Rate 0.1, temp 600 (750), stress 28 (13–18); rate 0.01, temp 600 (750), stress 14 (8–9).

Aluminum alloy 17 *S* (Duralumin): Rate 0.1, temp 300 (500) [600], stress 22 (5) [1.5].

Lead pure (commercial) (0.03 percent Ca): At 110°F, for rate 0.1 percent the stress range, lb/in^2, is 150–180 (60–140) [200–220]; for rate of 0.01 percent, 50–90 (10–50) [110–150].

Stress, 1,000 lb/in^2 × 6.894 = stress, MN/m^2, $t_k = \frac{5}{9}(t_F + 459.67)$.

Structural changes may occur during a creep test, thus altering the metallurgical condition of the metal. In some cases, premature rupture appears at a low fracture strain in a normally ductile metal, indicating that the material has become embrittled. This is a very insidious condition and difficult to predict. The **stress-rupture test** is well adapted to study this effect. It is conducted by applying a constant load to the specimen in the same manner as for the long-time creep test. The nominal stress is then plotted vs. the time for fracture at constant temperature on a log-log scale (Fig. 5.1.21).

The stress reaction is measured in the **constant-strain-rate test** while the specimen is deformed at a constant strain rate. In the **relaxation test,** the decrease of stress with time is measured while the total strain (elastic + plastic) is maintained constant. The latter test has direct application to the loosening of turbine bolts and to similar problems. Although some correlation has been indicated between the results

Table 5.1.6 Stresses for Given Creep Rates and Temperatures*

	Creep rate 0.1% per 1,000 h					Creep rate 0.01% per 1,000 h

* Based on 1,000-h tests. Stresses in 1,000 lb/in^2.
† Additional data. At creep rate 0.1 percent and 1,000 (1,600)°F the stress is 18–25 (1); at creep rate 0.01 percent at 1,500°F, the stress is 0.5.
‡ Additional data. At creep rate 0.1 percent and 1,000 (1,600)°F the stress is 10–30 (1).
§ Additional data. At creep rate 0.1 percent and 1,600°F the stress is 3; at creep rate 0.01 and 1,500°F, the stress is 2–3.

of these various types of tests, no general correlation is yet available, and it has been found necessary to make tests under each of these special conditions to obtain satisfactory results.

The interrelationship between strain rate and temperature in the form of a velocity-modified temperature (see MacGregor and Fisher, A Velocity-modified Temperature for the Plastic Flow of Metals, *Jour. Appl. Mech.,* Mar. 1945) simplifies the creep problem in reducing the number of variables.

Superplasticity Superplasticity is the property of some metals and alloys which permits extremely large, uniform deformation at elevated temperature, in contrast to conventional metals which neck down and subsequently fracture after relatively small amounts of plastic deformation. Superplastic behavior requires a metal with small equiaxed grains, a slow and steady rate of deformation (strain rate), and a temperature elevated to somewhat more than half the melting point. With such metals, large plastic deformation can be brought about with lower external

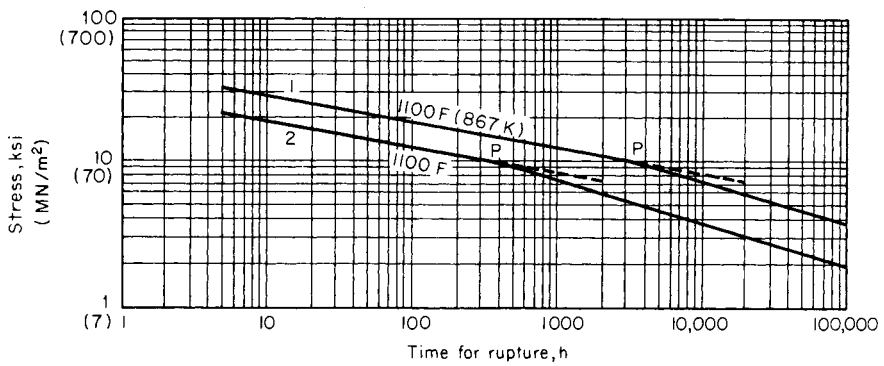

Fig. 5.1.21 Relation between time to failure and stress for a 3% chromium steel. (1) Heat treated 2 h at 1,740°F (950°C) and furnace cooled; (2) hot rolled and annealed 1,580°F (860°C).

loads; ultimately, that allows the use of lighter fabricating equipment and facilitates production of finished parts to near-net shape.

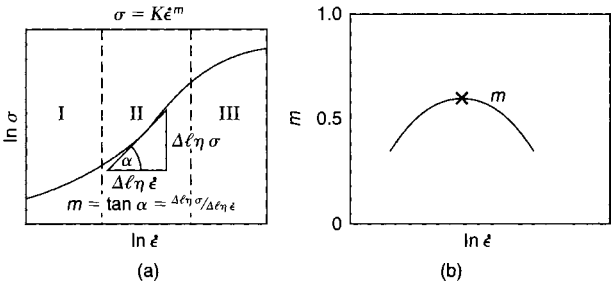

Fig. 5.1.22 Stress and strain rate relations for superplastic alloys. (*a*) Log-log plot of $\sigma = K\dot{\varepsilon}^m$; (*b*) *m* as a function of strain rate.

Stress and strain rates are related for a metal exhibiting superplasticity. A factor in this behavior stems from the relationship between the applied stress and strain rates. This factor *m*—the strain rate sensitivity index—is evaluated from the equation $\sigma = K\dot{\varepsilon}^m$, where σ is the applied stress, *K* is a constant, and $\dot{\varepsilon}$ is the strain rate. Figure 5.1.22*a* plots a stress/strain rate curve for a superplastic alloy on log-log coordinates. The slope of the curve defines *m*, which is maximum at the point of inflection. Figure 5.1.22*b* shows the variation of *m* versus ln $\dot{\varepsilon}$. Ordinary metals exhibit low values of *m*—0.2 or less; for those behaving superplastically, $m = 0.6$ to $0.8 +$. As *m* approaches 1, the behavior of the metal will be quite similar to that of a newtonian viscous solid, which elongates plastically without necking down.

In Fig. 5.1.22*a*, in region I, the stress and strain rates are low and creep is predominantly a result of diffusion. In region III, the stress and strain rates are highest and creep is mainly the result of dislocation and slip mechanisms. In region II, where superplasticity is observed, creep is governed predominantly by grain boundary sliding.

Shape Memory

Some particular alloys have a remarkable property which may be quite useful. The **shape memory effect** inherent in an alloy is a thermoelastic property that results from a reversible martensitic transformation when heated or cooled within a range of temperatures below the melting point. In essence, a given geometry at elevated temperature is cooled and further deformed. Upon being heated to the previous elevated temperature, the deformation imparted at the lower temperature is negated, and the former elevated-temperature geometry is restored. A number of useful applications have been found for those alloys which have this property.

HARDNESS

Hardness has been variously defined as resistance to local penetration, to scratching, to machining, to wear or abrasion, and to yielding. The multiplicity of definitions, and corresponding multiplicity of hardness-measuring instruments, together with the lack of a fundamental definition, indicates that hardness may not be a fundamental property of a material but rather a composite one including yield strength, work hardening, true tensile strength, modulus of elasticity, and others.

Scratch hardness is measured by **Mohs scale** of minerals (Sec. 1.2) which is so arranged that each mineral will scratch the mineral of the next lower number. In recent mineralogical work and in certain microscopic metallurgical work, jeweled scratching points either with a set load or else loaded to give a set width of scratch have been used. Hardness in its relation to machinability and to wear and abrasion is generally dealt with in direct machining or wear tests, and little attempt is made to separate hardness itself, as a numerically expressed quantity, from the results of such tests.

The resistance to localized penetration, or **indentation hardness,** is widely used industrially as a measure of hardness, and indirectly as an indicator of other desired properties in a manufactured product. The indentation tests described below are essentially nondestructive, and in most applications may be considered nonmarring, so that they may be applied to each piece produced; and through the empirical relationships of hardness to such properties as tensile strength, fatigue strength, and impact strength, pieces likely to be deficient in the latter properties may be detected and rejected.

Brinell hardness is determined by forcing a hardened sphere under a known load into the surface of a material and measuring the diameter of the indentation left after the test. The **Brinell hardness number,** or simply the **Brinell number,** is obtained by dividing the load used, in kilograms, by the actual surface area of the indentation, in square millimetres. The result is a pressure, but the units are rarely stated.

$$\text{BHN} = P \Big/ \left[\frac{\pi D}{2} (D - \sqrt{D^2 - d^2}) \right]$$

where BHN is the Brinell hardness number; *P* the imposed load, kg; *D* the diameter of the spherical indenter, mm; and *d* the diameter of the resulting impression, mm.

Hardened-steel bearing balls may be used for hardness up to 450, but beyond this hardness specially treated steel balls or jewels should be used to avoid flattening the indenter. The standard-size ball is 10 mm and the standard loads 3,000, 1,500, and 500 kg, with 100, 125, and 250 kg sometimes used for softer materials. If for special reasons any other size of ball is used, the load should be adjusted approximately as follows: for iron and steel, $P = 30D^2$; for brass, bronze, and other soft metals, $P = 5D^2$; for extremely soft metals, $P = D^2$ (see "Methods of Brinell Hardness Testing," ASTM). Readings obtained with other than the standard ball and loadings should have the load and ball size appended, as such readings are only approximately equal to those obtained under standard conditions.

The size of the specimen should be sufficient to ensure that no part of the plastic flow around the impression reaches a free surface, and in no case should the thickness be less than 10 times the depth of the impression. The load should be applied steadily and should remain on for at least 15 s in the case of ferrous materials and 30 s in the case of most nonferrous materials. Longer periods may be necessary on certain soft materials that exhibit creep at room temperature. In testing thin materials, it is not permissible to pile up several thicknesses of material under the indenter, as the readings so obtained will invariably be lower than the true readings. With such materials, smaller indenters and loads, or different methods of hardness testing, are necessary.

In the standard Brinell test, the diameter of the impression is measured with a low-power hand microscope, but for production work several testing machines are available which automatically measure the depth of the impression and from this give readings of hardness. Such machines should be calibrated frequently on test blocks of known hardness.

In the **Rockwell method** of hardness testing, the depth of penetration of an indenter under certain arbitrary conditions of test is determined. The indenter may be either a steel ball of some specified diameter or a spherical-tipped conical diamond of 120° angle and 0.2-mm tip radius, called a "Brale." A *minor load* of 10 kg is first applied which causes an initial penetration and holds the indenter in place. Under this condition, the dial is set to zero and the major load applied. The values of the latter are 60, 100, or 150 kg. Upon removal of the major load, the reading is taken while the minor load is still on. The hardness number may then be read directly from the scale which measures penetration, and this scale is so arranged that soft materials with deep penetration give low hardness numbers.

A variety of combinations of indenter and major load are possible; the most commonly used are R_B using as indenter a 1/16-in ball and a major load of 100 kg and R_C using a Brale as indenter and a major load of 150 kg (see "Rockwell Hardness and Rockwell Superficial Hardness of Metallic Materials," ASTM).

Compared with the Brinell test, the Rockwell method makes a smaller indentation, may be used on thinner material, and is more rapid, since hardness numbers are read directly and need not be calculated. However, the Brinell test may be made without special apparatus and is somewhat more widely recognized for laboratory use. There is also a **Rockwell superficial hardness test** similar to the regular Rockwell, except that the indentation is much shallower.

The **Vickers** method of hardness testing is similar in principle to the Brinell in that it expresses the result in terms of the pressure under the indenter and uses the same units, kilograms per square millimetre. The indenter is a diamond in the form of a square pyramid with an apical angle of 136°, the loads are much lighter, varying between 1 and 120 kg, and the impression is measured by means of a medium-power compound microscope.

$$V = P/(0.5393d^2)$$

where V is the Vickers hardness number, sometimes called the **diamond-pyramid hardness** (DPH); P the imposed load, kg; and d the diagonal of indentation, mm. The Vickers method is more flexible and is considered to be more accurate than either the Brinell or the Rockwell, but the equipment is more expensive than either of the others and the Rockwell is somewhat faster in production work.

Among the other hardness methods may be mentioned the **Scleroscope,** in which a diamond-tipped "hammer" is dropped on the surface and the rebound taken as an index of hardness. This type of apparatus is seriously affected by the resilience as well as the hardness of the material and has largely been superseded by other methods. In the **Monotron** method, a penetrator is forced into the material to a predetermined depth and the load required is taken as the indirect measure of the hardness. This is the reverse of the Rockwell method in principle, but the loads and indentations are smaller than those of the latter. In the **Herbert pendulum,** a 1-mm steel or jewel ball resting on the surface to be tested acts as the fulcrum for a 4-kg compound pendulum of 10-s period. The swinging of the pendulum causes a rolling indentation in the material, and from the behavior of the pendulum several factors in hardness, such as **work hardenability,** may be determined which are not revealed by other methods. Although the Herbert results are of considerable significance, the instrument is suitable for laboratory use only (see Herbert, The Pendulum Hardness Tester, and Some Recent Developments in Hardness Testing, *Engineer,* **135,** 1923, pp. 390, 686). In the **Herbert cloudburst** test, a shower of steel balls, dropped from a predetermined height, dulls the surface of a hardened part in proportion to its softness and thus reveals defective areas. A variety of **mutual indentation methods,** in which crossed cylinders or prisms of the material to be tested are forced together, give results comparable with the Brinell test. These are particularly useful on wires and on materials at high temperatures.

The relation among the scales of the various hardness methods is not exact, since no two measure exactly the same sort of hardness, and a relationship determined on steels of different hardnesses will be found only approximately true with other materials. The **Vickers-Brinell relation** is nearly linear up to at least 400, with the Vickers approximately 5 percent higher than the Brinell (actual values run from + 2 to + 11 percent) and nearly independent of the material. Beyond 500, the values become more widely divergent owing to the flattening of the Brinell ball. The **Brinell-Rockwell relation** is fairly satisfactory and is shown in Fig. 5.1.23. Approximate relations for the **Shore Scleroscope** are also given on the same plot.

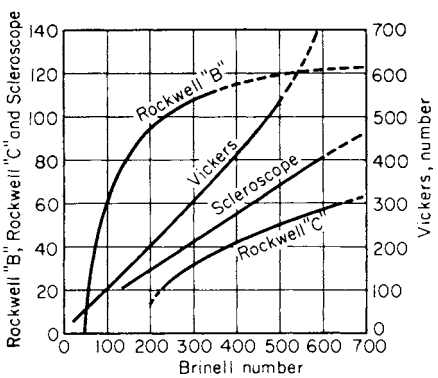

Fig. 5.1.23 Hardness scales.

The **hardness of wood** is defined by the ASTM as the load in pounds required to force a ball 0.444 in in diameter into the wood to a depth of 0.222 in, the speed of penetration being ¼ in/min. For a summary of the work in hardness see Williams, "Hardness and Hardness Measurements," ASM.

TESTING OF MATERIALS

Testing Machines Machines for the mechanical testing of materials usually contain elements (1) for gripping the specimen, (2) for deforming it, and (3) for measuring the load required in performing the deformation. Some machines (ductility testers) omit the measurement of load and substitute a measurement of deformation, whereas other machines include the measurement of both load and deformation through apparatus either integral with the testing machine (stress-strain recorders) or auxiliary to it (strain gages). In most general-purpose testing machines, the deformation is controlled as the independent variable and the resulting load measured, and in many special-purpose machines, particularly those for light loads, the load is controlled and the resulting deformation is measured. Special features may include those for constant rate of loading (pacing disks), for constant rate of straining, for constant load maintenance, and for cyclical load variation (fatigue).

In modern testing systems, the load and deformation measurements are made with load-and-deformation-sensitive transducers which generate electrical outputs. These outputs are converted to load and deformation readings by means of appropriate electronic circuitry. The readings are commonly displayed automatically on a recorder chart or digital meter, or they are read into a computer. The transducer outputs are typically used also as feedback signals to control the test mode (constant loading, constant extension, or constant strain rate). The load transducer is usually a load cell attached to the test machine frame, with electrical output to a bridge circuit and amplifier. The load cell operation depends on change of electrical resistivity with deformation (and load) in the transducer element. The deformation transducer is generally an extensometer clipped on to the test specimen gage length, and operates on the same principle as the load cell transducer: the change in electrical resistance in the specimen gage length is sensed as the specimen deforms. Optical extensometers are also available which do not make physical contact with the specimen. Verification and classification of extensometers is controlled by ASTM Standards. The application of load and deformation to the specimen is usually by means of a screw-driven mechanism, but it may also be applied by means of hydraulic and servohydraulic systems. In each case the load application system responds to control inputs from the load and deformation transducers. Important features in test machine design are the methods used for reducing friction, wear, and backlash. In older testing machines, test loads were determined from the machine itself (e.g., a pressure reading from the machine hydraulic pressure) so that machine friction made an important contribution to inaccuracy. The use of machine-independent transducers in modern testing has eliminated much of this source of error.

Grips should not only hold the test specimen against slippage but should also apply the load in the desired manner. Centering of the load is of great importance in compression testing, and should not be neglected in tension testing if the material is brittle. Figure 5.1.24 shows the theoretical errors due to off-center loading; the results are directly applicable to compression tests using swivel loading blocks. Swivel (ball-and-socket) holders or compression blocks should be used with all except the most ductile materials, and in compression testing of brittle materials (concrete, stone, brick), any rough faces should be smoothly capped with plaster of paris and one-third portland cement. Serrated grips may be used to hold ductile materials or the shanks of other holders in tension; a taper of 1 in 6 on the wedge faces gives a self-tightening action without excessive jamming. Ropes are ordinarily held by wet eye splices, but braided ropes or small cords may be given several turns over a fixed pin and then clamped. Wire ropes should be zinced into forged sockets (solder and lead have insufficient strength). Grip selection for tensile testing is described in ASTM standards.

Accuracy and Calibration ASTM standards require that commercial machines have errors of less than 1 percent within the "loading range" when checked against acceptable standards of comparison at at least five suitably spaced loads. The "loading range" may be any range through which the preceding requirements for accuracy are satisfied, except that it shall not extend below 100 times the least load to which the machine will respond or which can be read on the indicator. The use of calibration plots or tables to correct the results of an otherwise inaccurate machine is not permitted under any circumstances. Machines with errors less than 0.1 percent are commercially available (Tate-Emery and others), and somewhat greater accuracy is possible in the most refined research apparatus.

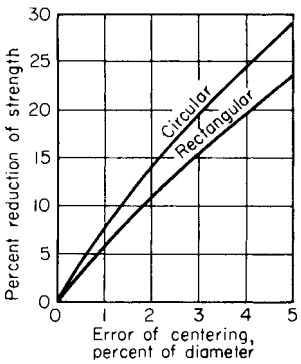

Fig. 5.1.24 Effect of centering errors on brittle test specimens.

Dead loads may be used to check machines of low capacity; accurately calibrated proving levers may be used to extend the range of available weights. Various elastic devices (such as the Morehouse proving ring) made of specially treated steel, with sensitive disortion-measuring devices, and calibrated by dead weights at the NIST (formerly Bureau of Standards) are among the most satisfactory means of checking the higher loads.

Two **standard forms of test specimens** (ASTM) are shown in Figs. 5.1.25 and 5.1.26. In wrought materials, and particularly in those which

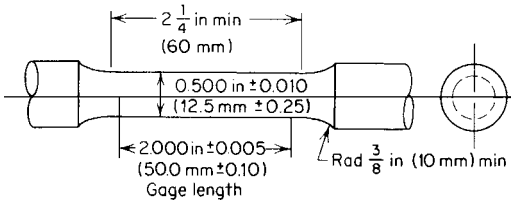

Fig. 5.1.25 Test specimen, 2-in (50-mm) gage length, ½-in (12.5-mm) diameter. Others available for 0.35-in (8.75-mm) and 0.25-in (6.25-mm) diameters. *(ASTM).*

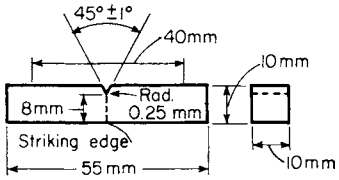

Fig. 5.1.26 Charpy V-notch impact specimens. *(ASTM.)*

have been cold-worked, different properties may be expected in different directions with respect to the direction of the applied work, and the test specimens, often called **coupons,** should be cut out from the parent material in such a way as to give the strength in the desired direction. With the exception of fatigue specimens and specimens of extremely brittle materials, surface finish is of little practical importance, although extreme roughness tends to decrease the ultimate elongation.

NOTE: The almost universal availability and utilization of computers in engineering practice has led to the development of many forms of software individually tailored to the solution of specific design problems in the area of mechanics of materials. Their use will permit the reader to amplify and supplement a good portion of the formulary and tabular collection in this section, as well as utilize those powerful computational tools in newer and more powerful techniques to facilitate solutions to problems. Many of the approximate methods, involving laborious iterative mathematical schemes, have been supplanted by the computer. Developments along those lines continue apace and bid fair to expand the types of problems handled, all with greater confidence in the results obtained thereby.

Main Symbols

UNIT STRESS

S = apparent stress
S_v or S_s = pure shearing
T = true (ideal) stress
S_p = proportional elastic limit
S_y = yield point
S_M = ultimate strength, tension
S_c = ultimate compression
S_v = vertical shear in beams
S_R = modulus of rupture

MOMENT

M = bending
M_t = torsion

EXTERNAL ACTION

P = force
G = weight of body
W = weight of load
V = external shear

MODULUS OF ELASTICITY

E = longitudinal
G = shearing
K = bulk
U_p = modulus of resilience
U_R = ultimate resilience

GEOMETRIC

l = length
A = area
V = volume
v = velocity
r = radius of gyration
I = rectangular moment of inertia
I_P or J = polar moment of inertia

DEFORMATION

e, e' = gross deformation
ε, ε' = unit deformation; strain
d or α = unit, angular
s' = unit, lateral
μ = Poisson's ratio
n = reciprocal of Poisson's ratio
r = radius
f = deflection

SIMPLE STRESSES AND STRAINS

Deformations are changes in form produced by external forces or loads that act on nonrigid bodies. Deformations are **longitudinal,** e, a lengthening (+) or shortening (−) of the body; and **angular,** α, a change of angle between the faces.

Unit deformation (strain) (dimensionless number) is the deformation in unit distance. Unit longitudinal deformation (longitudinal strain), $\varepsilon = e/l$ (Fig. 5.2.1). Unit angular-deformation tan α equals α approx (Fig. 5.2.2).

The accompanying lateral deformation results in unit lateral deformation (lateral strain) $\varepsilon' = e'/l'$ (Fig. 5.2.1). For homogeneous, isotropic material operating in the elastic region, the ratio $-\varepsilon'/\varepsilon$ is a constant and is a definite property of the material; this ratio is called **Poisson's ratio** μ.

A fundamental relation among the **three interdependent constants** E, G, and μ for a given material is $E = 2G(1 + \mu)$. Note that μ cannot be larger than 0.5; thus the shearing modulus G is always smaller than the elastic modulus E. At the extremes, for example, $\mu \approx 0.5$ for rubber and paraffin; $\mu \approx 0$ for cork. For concrete, μ varies from 0.10 to 0.20 at working stresses and can reach 0.25 at higher stresses; μ for ordinary glass is about 0.25. In the absence of definitive data, μ for most structural metals can be taken to lie between 0.25 and 0.35. Extensive listings of Poisson's ratio are found in other sections; see Tables 5.1.3 and 6.1.9.

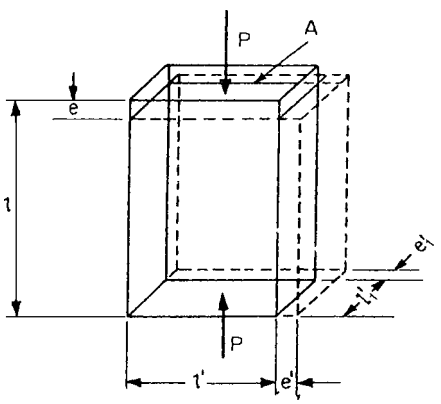

Fig. 5.2.1

Stress is an internal distributed force, or, force per unit area; it is the internal mechanical reaction of the material accompanying deformation. Stresses always occur in pairs. Stresses are **normal** [tensile stress (+) and compressive stress (−)]; and **tangential,** or **shearing.**

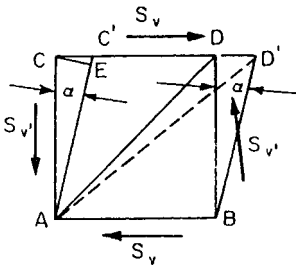

Fig. 5.2.2

Intensity of stress, or **unit stress,** S, lb/in^2 (kgf/cm^2), is the amount of force per unit of area (Fig. 5.2.3). P is the load acting through the center of gravity of the area. The uniformly distributed normal stress is

$$S = P/A$$

When the stress is not uniformly distributed, $S = dP/dA$.

A **long rod** will stretch under its own weight G and a terminal load P (see Fig. 5.2.4). The total elongation e is that due to the terminal load plus that due to one-half the weight of the rod considered as acting at the end.

$$e = (Pl + Gl/2)/(AE)$$

The maximum stress is at the upper end.

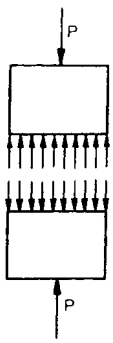

Fig. 5.2.3

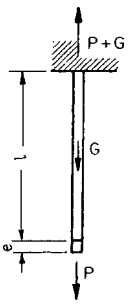

Fig. 5.2.4

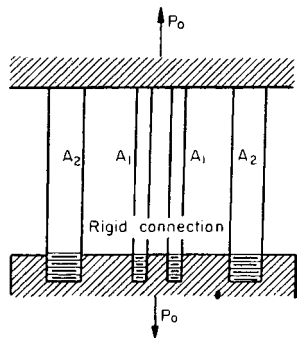

Fig. 5.2.5

When a **load** is **carried by several paths** to a support, the different paths take portions of the load in proportion to their stiffness, which is controlled by material *(E)* and by design.

EXAMPLE. Two pairs of bars rigidly connected (with the same elongation) carry a load P_0 (Fig. 5.2.5). A_1, A_2 and E_1, E_2 and P_1, P_2 and S_1, S_2 are cross sections, moduli of elasticity, loads, and stresses of the bars, respectively; e = elongation.

$$e = P_1 l/(E_1 A_1) = P_2 l/(E_2 A_2)$$

$$P_0 = 2P_1 + 2P_2$$

$$S_2 = P_2/A_2 = \tfrac{1}{2}[P_0 E_2/(E_1 A_1 + E_2 A_2)]$$

$$S_1 = \tfrac{1}{2}[P_0 E_1/(E_1 A_1 + E_2 A_2)]$$

Shearing stresses (Fig. 5.2.2) act tangentially to surface of contact and do not change length of sides of elementary volume; they **change the angle between faces** and the **length of diagonal.** Two pairs of shearing stresses must act together. **Shearing stress intensities are of equal magnitude on all four faces of an element.** $S_v = S'_v$ (Fig. 5.2.6).

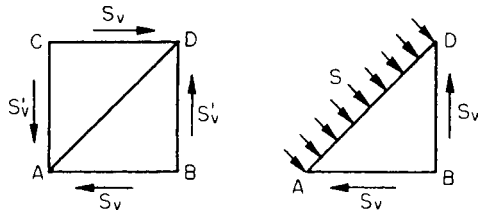

Fig. 5.2.6

In the presence of **pure shear** on external faces (Fig. 5.2.6), the **resultant stress** S on one diagonal plane at 45° is pure tension and on the other diagonal plane pure compression; $S = S_v = S'_v$. Failure under pure shear is difficult to produce experimentally, except under torsion and in certain special cases. Figure 5.2.7 shows an ideal case, and Fig. 5.2.8 a common form of test piece that introduces bending stresses.

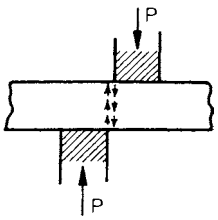

Fig. 5.2.7

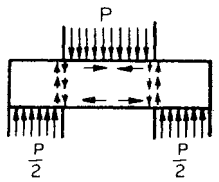

Fig. 5.2.8

Let Fig. 5.2.9 represent the symmetric section of area A with a shearing force V acting through its centroid. If pure shear exists, $S_v = V/A$, and this shear would be uniformly distributed over the area A. When this **shear** is **accompanied by bending (transverse shear in beams),** the unit

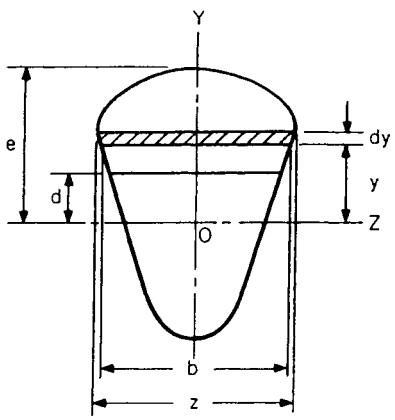

Fig. 5.2.9

shear S_v increases from the extreme fiber to its maximum, which may or may not be at the neutral axis OZ. The unit shear parallel to OZ at a point d distant from the neutral axis (Fig. 5.2.9) is

$$S_v = \frac{V}{Ib}\int_d^e yz\,dy$$

where z = the section width at distance y; and I is the moment of inertia of the **entire** section about the neutral axis OZ. Note that $\int_d^e yz\,dy$ is the first moment of the area above d with respect to axis OZ. For a **rectangular cross section** (Fig. 5.2.10a),

$$S_v = \frac{3}{2}\frac{V}{bh}\left[1 - \left(\frac{2y}{h}\right)^2\right]$$

$$S_v(\max) = \frac{3}{2}\frac{V}{bh} = \frac{3}{2}\frac{V}{A} \qquad \text{for } y = 0$$

For a **circular cross section** (Fig. 5.2.10b),

$$S_v = \frac{4}{3}\frac{V}{\pi r^2}\left[1 - \left(\frac{y}{r}\right)^2\right]$$

$$S_v(\max) = \frac{4}{3}\frac{V}{\pi r^2} = \frac{4}{3}\frac{V}{A} \qquad \text{for } y = 0$$

For a **circular ring** (thickness small in comparison with the major diameter), $S_v(\max) = 2V/A$, for $y = 0$.

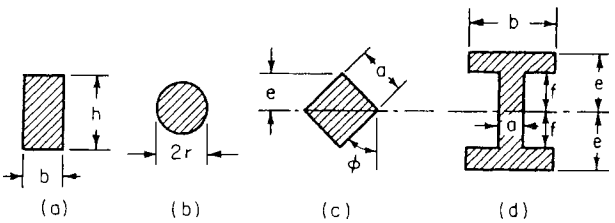

Fig. 5.2.10

For a **square cross section** (diagonal vertical, Fig. 5.2.10c),

$$S_v = \frac{V\sqrt{2}}{a^2}\left[1 + \frac{y\sqrt{2}}{a} - 4\left(\frac{y}{2}\right)^2\right]$$

$$S_v(\max) = 1.591\frac{V}{A} \qquad \text{for } y = \frac{e}{4}$$

For an **I-shaped cross section** (Fig. 5.2.10d),

$$S_v(\max) = \frac{3}{4}\frac{V}{a}\left[\frac{be^2 - (b-a)f^2}{be^3 - (b-a)f^3}\right] \qquad \text{for } y = 0$$

Consider a beam of uniform cross section that is subjected to a bending moment M. **Bending stress,** or the flexure formula, of the beam is $S = -My/I$, where y is the distance from the neutral axis and I is the moment of inertia of the cross section. For a circular cross section beam that is subjected to **torsion** M_t, pure shear stress in the beam is $S_s = M_t r/J$, where r is the radius of the cross section.

Elasticity is the ability of a material to return to its original dimensions after the removal of stresses. The **elastic limit** S_p is the limit of stress within which the deformation completely disappears after the removal of stress; i.e., no set remains.

Hooke's law states that, within the elastic limit, deformation produced is proportional to the stress. Unless modified, the deduced formulas of mechanics apply only within the elastic limit. Beyond this, they are modified by experimental coefficients, as, for instance, the modulus of rupture.

The modulus of elasticity, lb/in^2 (kgf/cm^2), is the ratio of the increment of unit stress to increment of unit deformation within the elastic limit.

The modulus of elasticity in tension, or **Young's modulus,**

$$E = \text{unit stress/unit deformation} = Pl/(Ae)$$

The modulus of elasticity in compression is similarly measured.

The **modulus of elasticity in shear** or **coefficient of rigidity,** $G = S_v/\alpha$ where α is expressed in radians (see Fig. 5.2.2).

The **bulk modulus of elasticity** K is the ratio of normal stress, applied to all six faces of a cube, to the change of volume.

Change of volume under normal stress is so small that it is rarely of significance. For example, given a body with length l, width b, thickness d, Poisson's ratio μ, and longitudinal strain ε, $V = lbd$ = original volume. The deformed volume $= (1 + \varepsilon)l(1 - \mu\varepsilon)b(1 - \mu\varepsilon)d$. Neglecting powers of ε, the deformed volume $= (1 + \varepsilon - 2\mu\varepsilon)V$. The change in volume is $\varepsilon(1 - 2\mu)V$; the **unit volumetric strain** is $\varepsilon(1 - 2\mu)$. Thus, a steel rod ($\mu = 0.3$, $E = 30 \times 10^6$ lb/in^2) compressed to a stress of 30,000 lb/in^2 will experience $\varepsilon = 0.001$ and a unit volumetric strain of 0.0004, or 1 part in 2,500.

The following relationships exist between the modulus of elasticity in tension or compression E, modulus of elasticity in shear G, bulk modulus of elasticity K, and Poisson's ratio μ:

$$E = 2G(1 + \mu)$$
$$G = E/[2(1 + \mu)]$$
$$\mu = (E - 2G)/(2G)$$
$$K = E/[3(1 - 2\mu)]$$
$$\mu = (3K - E)/(6K)$$

Resilience U (in · lb)[(cm · kgf)] is the potential energy stored up in a deformed body. The amount of resilience is equal to the work required to deform the body from zero stress to stress S, when S does not exceed the elastic limit. For normal stress, resilience = work of deformation = average force times deformation = $\frac{1}{2}Pe = \frac{1}{2}AS \times Sl/E = \frac{1}{2}\, S^2V/E$.

Modulus of resilience U_p (in · lb/in^3) [(cm · kgf/cm^3)], or **unit resilience,** is the **elastic energy** stored up in a cubic inch of material at the elastic limit. For normal stress,

$$U_p = \tfrac{1}{2}S_p^2/E$$

The unit resilience for any other kind of stress, as shearing, bending, torsion, is a constant times one-half the square of the stress divided by the appropriate modulus of elasticity. For values, see Table 5.2.1.

Unit rupture work U_R, sometimes called **ultimate resilience,** is measured by the area of the stress-deformation diagram to rupture.

$$U_R = \tfrac{1}{3}\, e_u(S_y + 2S_M) \qquad \text{approx}$$

where e_u is the total deformation at rupture.

For structural steel, $U_R = \frac{1}{3} \times \frac{27}{100} \times [35{,}000 + (2 \times 60{,}000)] = 13{,}950$ in · lb/in^3 (982 cm · kgf/cm^3).

EXAMPLE 1. A load $P = 40{,}000$ lb compresses a wooden block of cross-sectional area $A = 10$ in^2 and length $= 10$ in, an amount $e = \frac{4}{100}$ in. Stress $S = \frac{1}{10} \times 40{,}000 = 4{,}000$ lb/in^2. Unit elongation $s = \frac{4}{100} \div 10 = \frac{1}{250}$. Modulus of elasticity $E = 4{,}000 \div \frac{1}{250} = 1{,}000{,}000$ lb/in^2. Unit resilience $U_p = \frac{1}{2} \times 4{,}000 \times 4{,}000/1{,}000{,}000 = 8$ in · lb/in^3 (0.563 cm · kgf/cm^3).

EXAMPLE 2. A weight $G = 5{,}000$ lb falls through a height $h = 2$ ft; V = number of cubic inches required to absorb the shock without exceeding a stress of 4,000 lb/in^2. Neglect compression of block. Work done by falling weight $= Gh = 5{,}000 \times 2 \times 12$ in · lb (2,271 × 61 cm · kgf) Resilience of block $= V \times 8$ in · lb $= 5{,}000 \times 2 \times 12$. Therefore, $V = 15{,}000$ in^3 (245,850 cm^3).

Thermal Stresses A bar will change its length when its temperature is raised (or lowered) by the amount $\Delta l_0 = \alpha l_0(t_2 - 32)$. The linear **coefficient of thermal expansion** α is assumed constant at normal temperatures and l_0 is the length at 32°F (273.2 K, 0°C). If this expansion (or contraction) is prevented, a **thermal-time stress** is developed, equal to $S = E\alpha(t_2 - t_1)$, as the temperature goes from t_1 to t_2. In thin flat plates the stress becomes $S = E\alpha(t_2 - t_1)/(1 - \mu)$; μ is Poisson's ratio. Such stresses can occur in castings containing large and small sections. Similar stresses also occur when heat flows through members because of the difference in temperature between one point and another. The heat flowing across a length b as a result of a linear drop in temperature Δt equals $Q = kA\ \Delta t/b$ Btu/h (cal/h). The thermal conductivity k is in Btu/(h)(ft^2)(°F)/(in of thickness) [cal/(h)(m^2)(k)/(m)]. The **thermal-flow stress** is then $S = E\alpha Qb/(kA)$. Note, when Q is substituted the stress becomes $S = E\alpha\ \Delta t$ as above, only t is now a function of distance rather than time. For coefficient of thermal expansion α, see Sec. 4.

EXAMPLE. A cast-iron plate 3 ft square and 2 in thick is used as a fire wall. The temperature is 330°F on the hot side and 160°F on the other. What is the thermal-flow stress developed across the plate?

$$S = E\alpha\ \Delta t = 13 \times 10^6 \times 6.5 \times 10^{-6} \times 170$$
$$= 14{,}360 \text{ lb/in}^2\ (1{,}010 \text{ kgf/cm}^2)$$

or $$Q = 2.3 \times 9 \times 170/2 = 1{,}760 \text{ Btu/h}$$

and $$S = 13 \times 10^6 \times 6.5 \times 10^{-6} \times 1{,}760 \times 2/2.3 \times 9$$
$$= 14{,}360 \text{ lb/in}^2\ (1{,}010 \text{ kgf/cm}^2)$$

COMBINED STRESSES

In the discussion that follows, the element is subjected to stresses lying in one plane; this is the case of **plane stress,** or **two-dimensional stress**.

Simple stresses, defined as such by the flexure and torsion theories, lie in planes normal or parallel to the line of action of the forces. Normal, as well as shearing, stresses may, however, exist in other directions. A particle out of a loaded member will contain normal and shearing stresses as shown in Fig. 5.2.11. Note that the four shearing stresses must be of the same magnitude, if equilibrium is to be satisfied.

If the particle is "cut" along the plane AA, equilibrium will reveal that, in general, normal as well as shearing stresses act upon the plane

Table 5.2.1 Resilience per Unit of Volume U_p
(S = longitudinal stress; S_v = shearing stress; E = tension modulus of elasticity; G = shearing modulus of elasticity)

Tension or compression	$\frac{1}{2}S^2/E$	Torsion	
Shear	$\frac{1}{2}S_v^2/G$	Solid circular	$\frac{1}{4}S_v^2/G$
Beams (free ends)		Hollow, radii R_1 and R_2	$\dfrac{R_1^2 + R_2^2}{R_1^2}\,\dfrac{1}{4}\,\dfrac{S_v^2}{G}$
Rectangular section, bent in arc of circle; no shear	$\frac{1}{6}S^2/E$	Springs	
Ditto, circular section	$\frac{1}{8}S^2/E$	Carriage	$\frac{1}{6}S^2/E$
Concentrated center load; rectangular cross section	$\frac{1}{18}S^2/E$	Flat spiral, rectangular section	$\frac{1}{24}S^2/E$
Ditto, circular cross section	$\frac{1}{24}S^2/E$	Helical: axial load, circular wire	$\frac{1}{4}S_v^2/G$
Uniform load, rectangular cross section	$\frac{5}{36}S^2/E$	Helical: axial twist	$\frac{1}{8}S^2/E$
1-beam section, concentrated center load	$\frac{3}{32}S^2/E$	Helical: axial twist, rectangular section	$\frac{1}{6}S^2/E$

AC (Fig. 5.2.12). The normal stress on plane AC is labeled S_n, and shearing S_s. The application of equilibrium yields

$$S_n = \frac{S_x + S_y}{2} + \frac{S_x - S_y}{2}\cos 2\theta + S_{xy}\sin 2\theta$$

and

$$S_s = \frac{S_x - S_y}{2}\sin 2\theta - S_{xy}\cos 2\theta$$

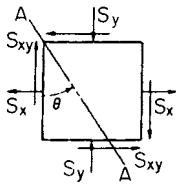

Fig. 5.2.11

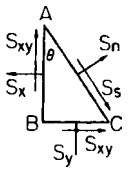

Fig. 5.2.12

A *sign convention* must be used. A tensile stress is positive while compression is negative. A shearing stress is positive when directed as on plane AB of Fig. 5.2.12; i.e., when the shearing stresses on the vertical planes form a clockwise couple, the stress is positive.

The planes defined by $\tan 2\theta = 2S_{xy}/S_x - S_y$, the *principal planes,* contain the **principal stresses**—the maximum and minimum normal stresses. These stresses are

$$S_M, S_m = \frac{S_x + S_y}{2} \pm \sqrt{\left(\frac{S_x - S_y}{2}\right)^2 + S_{xy}^2}$$

The maximum and minimum shearing stresses are represented by the quantity

$$S_{sM,m} = \pm\sqrt{\left(\frac{S_x - S_y}{2}\right)^2 + S_{xy}^2}$$

and they act on the planes defined by

$$\tan 2\theta = -\frac{S_x - S_y}{2S_{xy}}$$

EXAMPLE. The steam in a boiler subjects a particular particle on the outer surface of the boiler shell to a circumferential stress of 8,000 lb/in^2 and a longitudinal stress of 4,000 lb/in^2 as shown in Fig. 5.2.13. Find the stresses acting on the plane XX, making an angle of 60° with the direction of the 8,000 lb/in^2 stress. Find the principal stresses and locate the principal planes. Also find the maximum and minimum shearing stresses.

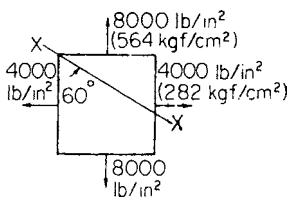

Fig. 5.2.13

$$60°\ S_n = \frac{4{,}000 + 8{,}000}{2} + \frac{4{,}000 - 8{,}000}{2}(-0.5000) + 0$$
$$= 7{,}000 \text{ lb/in}^2$$
$$60°\ S_s = \frac{4{,}000 - 8{,}000}{2}(0.8660) - 0 = -1{,}732 \text{ lb/in}^2$$

$$S_{M,m} = \frac{4{,}000 + 8{,}000}{2} \pm \sqrt{\left(\frac{4{,}000 - 8{,}000}{2}\right)^2 + 0}$$
$$= 6{,}000 \pm 2{,}000$$
$$= 8{,}000 \text{ and } 4{,}000 \text{ lb/in}^2 \ (564 \text{ and } 282 \text{ kgf/cm}^2)$$
$$\text{at } \tan 2\theta = \frac{2 \times 0}{4{,}000 - 8{,}000} = 0 \quad \text{or} \quad \theta = 90° \text{ and } 0°$$

$$S_{s\,M,m} = \pm\sqrt{\left(\frac{4{,}000 - 8{,}000}{2}\right)^2 + 0}$$
$$= \pm 2{,}000 \text{ lb/in}^2 \ (\pm 141 \text{ kgf/cm}^2)$$

Mohr's Stress Circle The biaxial stress field with its combined stresses can be represented graphically by the Mohr stress circle. For instance, for the particle given in Fig. 5.2.11, Mohr's circle is as shown in Fig. 5.2.14. The stress *sign convention* previously defined must be adhered to. Furthermore, in order to locate the point (on Mohr's circle) that yields the stresses on a plane $\theta°$ from the vertical side of the particle (such as plane AA in Fig. 5.2.11), $2\theta°$ must be laid off in the same

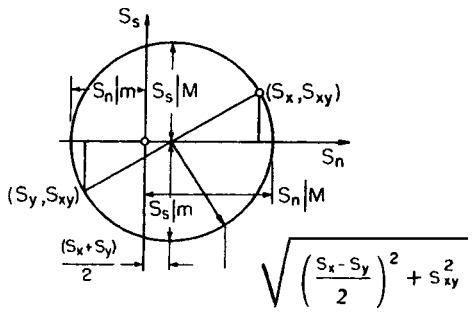

Fig. 5.2.14

direction from the radius to (S_x, S_{xy}). For the previous example, Mohr's circle becomes Fig. 5.2.15.

Eight special stress fields are shown in Figs. 5.2.16 to 5.2.23, along with Mohr's circle for each.

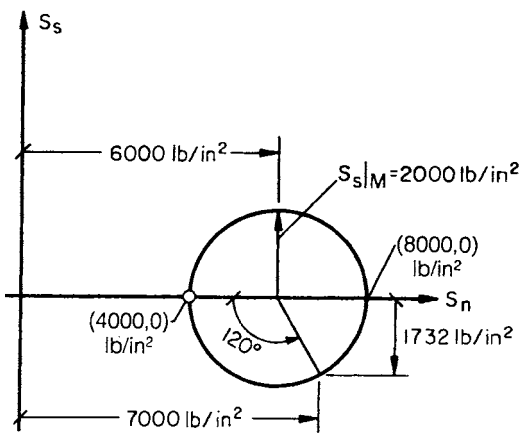

Fig. 5.2.15

Combined Loading **Combined flexure and torsion** arise, for instance, when a shaft twisted by a torque M_t is bent by forces produced by belts or gears. An element on the surface, such as $ABCD$ on the shaft of Fig. 5.2.24, is subjected to a **flexure stress** $S_x = Mc/I = 8Fl/(\pi d^3)$ and

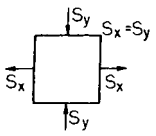

Fig. 5.2.16

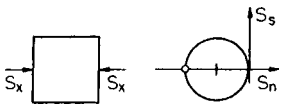

Fig. 5.2.17

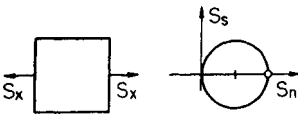

Fig. 5.2.18

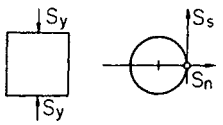

Fig. 5.2.19

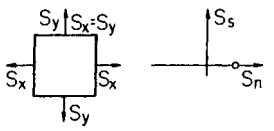

Fig. 5.2.20

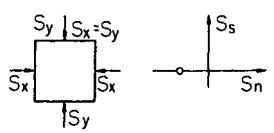

Fig. 5.2.21

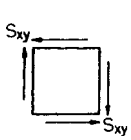

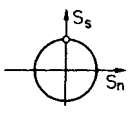

Fig. 5.2.22

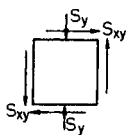

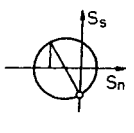

Fig. 5.2.23

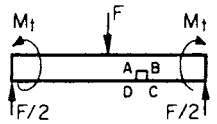
a **torsional shearing stress** $S_{xy} = M_t c/J = 16M_t/(\pi d^3)$. These stresses will induce combined stresses. The maximum combined stresses will be

$$S_n = \tfrac{1}{2}(S_x \pm \sqrt{S_x^2 + 4S_{xy}^2})$$

and

$$S_s = \pm \tfrac{1}{2}\sqrt{S_x^2 + 4S_{xy}^2}$$

The above situation appllies to any case of normal stress with shear, as when a bolt is under both tension and shear. A beam subjected to both flexure and transverse shear is another case.



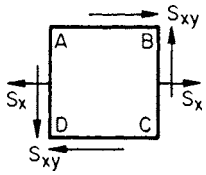


Fig. 5.2.24

Combined torsion and longitudinal loads exist on a propeller shaft. An element on this shaft will contain a tensile stress computed using $S = F/A$ and a torsion shearing stress equal to $S_s = M_t c/J$. The free body of an element on the surface of a vertical turbine shaft is subjected to direct compression and torsion.

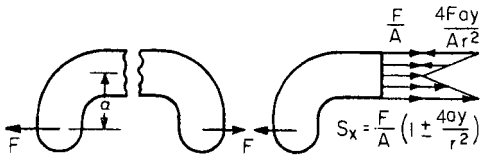

Fig. 5.2.25

When combined loading results in stresses of the same type and direction, the addition is algebraic. Such a situation exists on an offset link like that of Fig. 5.2.25.

Mohr's Strain Circle Strain equations can also be derived for plane-strain fields. Strains e_x and e_y are the extensional strains (tension or compression) occurring at a point in two right-angle directions, and the change of the angle between them is γ_{xy}. The strain e at the point in any direction a at an angle θ with the x direction derives as

$$e_a = \frac{e_x + e_y}{2} + \frac{e_x - e_y}{2}\cos 2\theta + \frac{\gamma_{xy}}{2}\sin 2\theta$$

Similarly, the shearing strain γ_{ab} (change in the original right angle between directions a and b) is defined by

$$\gamma_{ab} = (e_x - e_y)\sin 2\theta + \gamma_{xy}\cos 2\theta$$

Inspection easily reveals that the above equations for e_a and γ_{ab} are mathematically identical to those for S_n and S_s. Thus, once a sign convention is established, a Mohr circle for strain can be constructed and used as the stress circle is used. The strain e is positive when an extension and negative when a contraction. If the direction associated with the first subscript a rotates counterclockwise during straining with respect to the direction indicated by the second subscript b, the shearing strain is positive; if clockwise, it is negative. In constructing the circle, positive extensional strains will be plotted to the right as abscissas and positive **half-shearing** strains will be plotted upward as ordinates.

For the strains shown in Fig. 5.2.26*a*, Mohr's strain circle becomes that shown in Fig. 5.2.26*b*. The extensional strain in the direction a, making an angle of θ_a with the x direction, is e_a, and the shearing strain is γ_{ab} counterclockwise. The strain 90° away is e_b. The maximum principal strain is e_M at an angle θ_M clockwise from the x direction. The other principal or minimum strain is e_m 90° away.

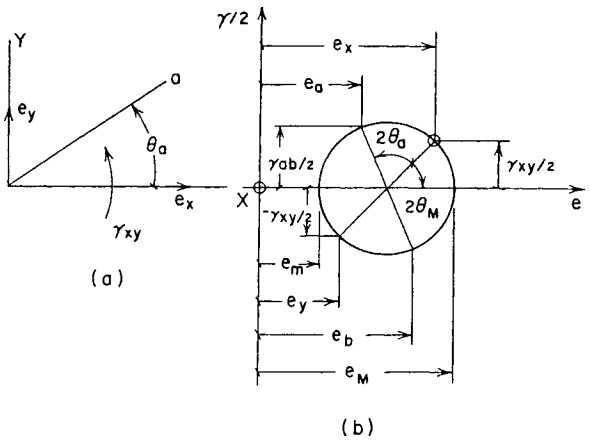

Fig. 5.2.26

PLASTIC DESIGN

Early efforts in stress analysis were based on limit loads, that is, loads which stress a member "wholly" to the yield strength. Euler's famous paper on column action ("Sur la Force des Colonnes," Academie des Sciences de Berlin, 1757) deals with the column problem this way. More recently, the concept of limit loads, referred to as **limit,** or **plastic, design,** has found strong application in the design of certain structures. The theory presupposes a ductile material, absence of stress raisers, and fabrication free of embrittlement. Local load overstress is allowed, provided the structure does not deform appreciably.

To visualize the limit-load approach, consider a simple beam of uniform section subjected to a concentrated load of midspan, as depicted in Fig. 5.2.27*a*. According to elastic theory, the outermost fiber on each side and at midspan—the section of maximum bending moment—will first reach the yield-strength value, Across the depth of the beam, the stress distribution will, of course, follow the triangular pattern, becoming zero at the neutral axis. If the material is ductile, the stress in the outermost fibers will remain at the yield value until every other fiber reaches the same value as the load increases. Thus the stress distribution assumes the rectangular pattern before the *plastic hinge* forms and failure ensues.

The problem is that of finding the final limit load. Elastic-flexure theory gives the maximum load—triangular distribution—as

$$F_y = \frac{2S_y bh^2}{3l}$$

For the rectangular stress distribution, the limit load becomes

$$F_L = \frac{S_y bh^2}{l}$$

The ratio $F_L/F_y = 1.50$—an increase of 50 percent in load capability. The ratio F_L/F_y has been named **shape factor** (Jenssen, Plastic Design in Welded Structures Promises New Economy and Safety, *Welding Jour.,* Mar. 1959). See Fig. 5.2.27*b* for shape factors for some other sections. The shape factor may also be determined by dividing the first moment of area about the neutral axis by the section modulus.

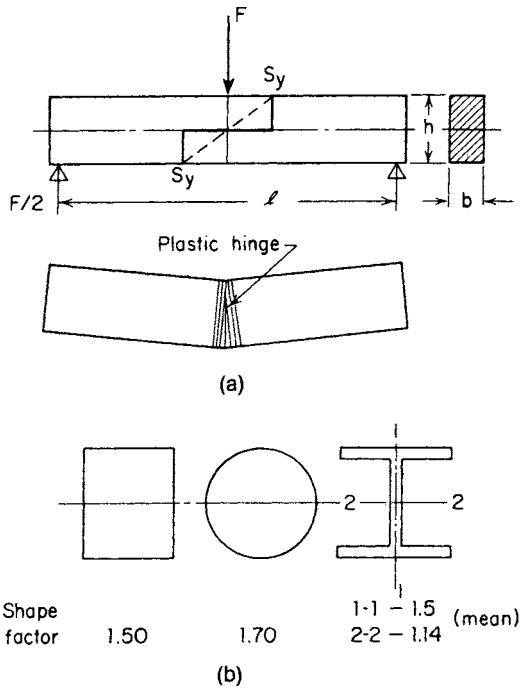

Fig. 5.2.27

A constant-section beam with both ends fixed, supporting a uniformly distributed load, illustrates another application of the plastic-load approach. The bending-moment diagram based on the elastic theory drawn in Fig. 5.2.28 (broken line) shows a moment at the center equal to one-half the moment at either end. A preferable situation, it might be argued, is one in which the moments are the same at the three stations—solid line. Thus, applying equilibrium to, say, the left half of the beam yields a bending moment at each of the three plastic hinges of

$$M_L = \frac{wl^2}{16}$$

DESIGN STRESSES

If a machine part is to safely transmit loads acting upon it, a permissible maximum stress must be established and used in the design. This is the allowable stress, the working stress, or preferably, the **design stress.** The design stress should not waste material, yet should be large enough to prevent failure in case loads exceed expected values, or other uncertainties react unfavorably.

The design stress is determined by dividing the applicable material property—yield strength, ultimate strength, fatigue strength—by a **factor of safety.** The factor should be selected only after all **uncertainties** have

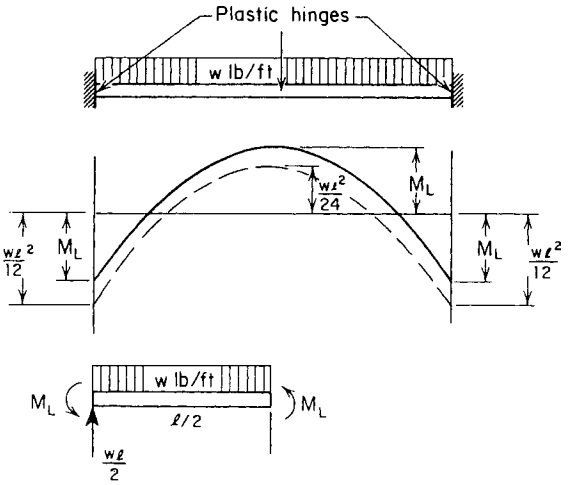

Fig. 5.2.28

been thoroughly considered. Among these are the uncertainty with respect to the magnitude and kind of operating load, the reliability of the material from which the component is made, the assumptions involved in the theories used, the environment in which the equipment might operate, the extent to which localized and fabrication stresses might develop, the uncertainty concerning causes of possible failure, and the endangering of human life in case of failure. Factors of safety vary from industry to industry, being the result of accumulated experience with a class of machines or a kind of environment. Many codes, such as the ASME code for power shafting, recommend design stresses found safe in practice.

In general, the **ductility** of the material determines the property upon which the factor should be based. Materials having an elongation of over 5 percent are considered ductile. In such cases, the factor of safety is based upon the yield strength or the endurance limit. For materials with an elongation under 5 percent, the ultimate strength must be used because these materials are **brittle** and so fracture without yielding.

Factors of safety based on yield are often taken **between 1.5 and 4.0.** For more reliable materials or well-defined design and operating conditions, the lower factors are appropriate. In the case of untried materials or otherwise uncertain conditions, the larger factors are safer. The same values can be used when loads vary, but in such cases they are applied to the fatigue or endurance strength. When the ultimate strength determines the design stress (in the case of brittle materials), the factors of safety can be doubled.

Thus, under static loading, the design stress for, say, SAE 1020, which has a yield strength of 45,000 lb/in^2 (3,170 kgf/cm^2) may be taken at 45,000/2, or 22,500 lb/in^2 (1,585 kgf/cm^2), if a reasonably certain design condition exists. A Class 30 cast-iron part might be designed at 30,000/5 or 6,000 lb/in^2 (423 kgf/cm^2). A 2017S-0 aluminum-alloy component (13,000 lb/in^2 endurance strength) could be computed at a design stress of 13,000/2.5 or 5,200 lb/in^2 (366 kgf/cm^2) in the usual fatigue-load application.

BEAMS

For properties of structural steel and wooden beams, see Sec. 12.2.

Notation

I = rectangular moment of inertia
I_p = polar moment of inertia
I/c = section modulus
M = bending moment
P, W' = concentrated load
Q or V = total vertical shear
R = reaction
S = unit normal stress

S_s or S_y = transverse shearing stress
W = total distributed load
f = deflection
i = slope
l = distance between supports
r = radius of gyration
r_c = radius of curvature
w = distributed load per longitudinal unit

A **simple beam** rests on supports at its ends which permit rotation. A **cantilever beam** is fixed (no rotation) at one end. When computing reactions and moments, distributed loads may be replaced by their resultants acting at the center of gravity of the distributed-load area.

Reactions are the forces and/or couples acting at the supports and holding the beam in place. In general, the weight of the beam should be accounted for.

The **bending moment** (pound-feet or pound-inches) (kgf · m) at any section is the algebraic sum of the external forces and moments acting on the beam on one side of the section. It is also equal to the moment of the internal-stress forces at the section, $M = \int s\,dA/y$. A bending moment that bends a beam convex downward (tensile stress on bottom fiber) is considered **positive,** while convex upward (compression on bottom) is **negative.**

The **vertical shear** V (lb) (kgf) effective on a section is the algebraic sum of all the forces acting parallel to and on one side of the section, $V = \Sigma F$. It is also equal to the sum of the transverse shear stresses acting on the section, $V = \int S_s\,dA$.

Moment and **shear diagram** may be constructed by plotting to scale the particular entity as the ordinate for each section of the beam. Such diagrams show in continuous form the variation along the length of the beam.

Moment-Shear Relation The shear V is the first derivative of moment with respect to distance along the beam, $V = dM/dx$. This relationship does not, however, account for any sudden changes in moment.

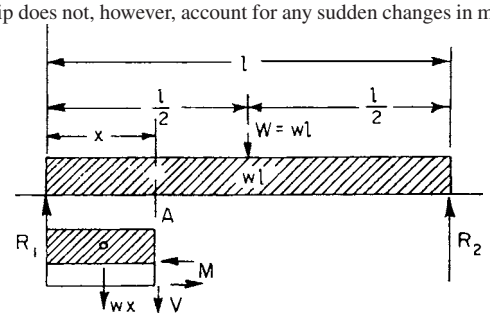

Fig. 5.2.29

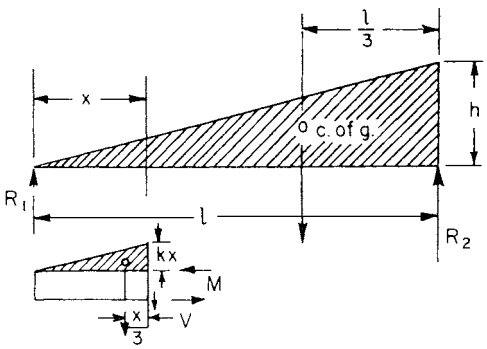

Fig. 5.2.30

EXAMPLES. Figure 5.2.29 illustrates a simple beam subjected to a uniform load. $M = R_1x - wx \times \frac{x}{2} = \frac{w/x}{2} - \frac{wx^2}{2}$ and $V = R_1 - wx = \frac{wl}{2} - wx$. Note also that $V = \frac{d}{dx}\left(\frac{wlx}{2} - \frac{wx^2}{2}\right) = \frac{wl}{2} - wx$.

Figure 5.2.30 is a simple beam carrying a uniformly varying load; $M = R_1x - h\frac{x}{1} \times \frac{x}{2} \times \frac{x}{3} = \frac{hlx}{6} - \frac{hx^3}{6l}$, if h is in pounds per foot and weight of beam is neglected. The vertical shear $V = R_1 - \frac{hx}{1} \times \frac{x}{2} = \frac{hl}{6} - \frac{hx^2}{2l}$. Note again that $V = \frac{d}{dx}\left(\frac{hlx}{6} - \frac{hx^3}{6l}\right) = \frac{hl}{6} - \frac{hx^2}{2l}$.

Table 5.2.2 gives the reactions, bending-moment equations, vertical shear equations, and the deflection of some of the more common types of beams.

Maximum Safe Load on Steel Beams See Table 5.2.3 To obtain maximum safe load (or maximum deflection under maximum safe load) for any of the conditions of loading given in Table 5.2.5, multiply the corresponding coefficient in that table by the greatest safe load (or deflection) for distributed load for the particular section under consideration as given in Table 5.2.4.

The following approximate factors for reducing the load should be used when beams are long in comparison with their breadth:

Ratio of unsupported (lateral) length to flange width or breadth	20	30	40	50	60	70
Ratio of greatest safe load to calculated load	1	0.9	0.8	0.7	0.6	0.5

Theory of Flexure A bent beam is shown in Fig. 5.2.31. The concave side is in compression and the convex side in tension. These are divided by the **neutral plane** of zero stress $A'B'BA$. The intersection of the neutral plane with the face of the beam is in the **neutral line or elastic curve** AB. The intersection of the neutral plane with the cross section is the **neutral axis** NN'.

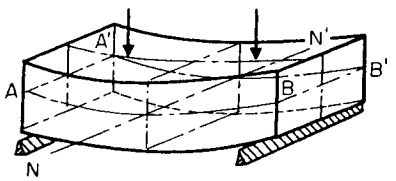

Fig. 5.2.31

It is assumed that a beam is prismatic, of a length at least 10 times its depth, and that the external forces are all at right angles to the axis of the beam and in a plane of symmetry, and that flexure is slight. Other assumptions are: (1) That the material is homogeneous, and obeys Hooke's law. (2) That **stresses are within the elastic limit.** (3) That every layer of material is free to expand and contract longitudinally and laterally under stress as if separate from other layers. (4) That the tensile and compressive moduli of elasticity are equal. (5) That the cross section remains a plane surface. (The assumption of plane cross sections is strictly true only when the shear is constant or zero over the cross section, and when the shear is constant throughout the length of the beam.)

It follows then that: (1) The internal forces are in horizontal balance. (2) The **neutral axis contains the center of gravity** of the cross section, where there is no resultant axial stress. (3) The stress intensity varies directly with the distance from the neutral axis.

The moment of the elastic forces about the neutral axis, i.e., the **stress moment** or **moment of resistance,** is $M = SI/c$, where S is an elastic unit stress at outer fiber whose distance from the neutral axis is c; and I is the rectangular moment of inertia about the neutral axis. I/c is the **section modulus.**

This formula is for the **strength of beams.** For rectangular beams, $M = \frac{1}{6}Sbh^2$, where b = breadth and h = depth; i.e., the elastic **strength of beam sections** varies as follows: (1) for equal width, as the square of the depth; (2) for equal depth, directly as the width; (3) for equal depth

and width, directly as the strength of the material; (4) if span varies, then for equal depth, width, and material, inversely as the span.

If a beam is cut in halves vertically, the two halves laid side by side each will carry only one-half as much as the original beam.

Tables 5.2.6 to 5.2.8 give the properties of various beam cross sections. For properties of structural-steel shapes, see Sec. 12.2.

Oblique Loading It should be noted that Table 5.2.6 includes certain cases for which the horizontal axis is not a neutral axis, assuming the common case of vertical loading. The rectangular section with the diagonal as a horizontal axis (Table 5.2.6) is such a case. These cases must be handled by the principles of oblique loading.

Every section of a beam has two principal axes passing through the center of gravity, and these two axes are always at right angles to each other. The principal axes are axes with respect to which the moment of inertia is, respectively, a maximum and a minimum, and for which the product of inertia is zero. For symmetrical sections, axes of symmetry are always principal axes. For unsymmetrical sections, like a **rolled angle** section (Fig. 5.2.32), the inclination of the principal axis with the X axis may be found from the formula $\tan 2\theta = 2I_{xy}/(I_y - I_x)$, in which θ = angle of inclination of the principal axis to the X axis, I_{xy} = the product of inertia of the section with respect to the X and Y axes, I_y = moment of inertia of the section with respect to the Y axis, I_x = moment of inertia

* This table is convenient for wooden beams. For any other fiber stress S', multiply the values in table by S'/1,000. See Sec. 12.2 for properties of wooden beams of commercial sizes.
† To change to kgf, multiply by 0.454.
‡ To change to m, multiply by 0.305.
§ To change to cm, multiply by 2.54.

of the section with respect to the X axis. When this principal axis has been found, the other principal axis is at right angles to it.

Calling the moments of inertia with respect to the principal axes I'_x and I'_y, the unit stress existing anywhere in the section at a point whose coordinates are x and y (Fig. 5.2.33) is $S = My\cos\alpha/I'_x + Mx\sin\alpha/I'_y$, in which M = bending moment with respect to the section in question, α = the angle which the plane of bending moment or the plane of the loads makes with the y axis, $M\cos\alpha$ = the component of bending moment causing bending about the principal axis which has been designated as the X axis, $M\sin\alpha$ = the component of bending moment causing bending about the principal axis which has been designated as the Y axis. The sign of the two terms for unit stress may be determined by inspection in the usual way, and the result will be tension or compression as determined by the algebraic sum of the two terms.

Table 5.2.4 Approximate Safe Loads in Pounds (kgf) on Steel Beams,* Simply Supported, Single Span

Allowable fiber stress for steel, 16,000 lb/in^2 (1,127 kgf/cm^2) (basis of table)
Beams simply supported at both ends.
L = distance between supports, ft (m) — a = interior area, in^2 (cm^2)
A = sectional area of beam, in^2 (cm^2) — d = interior depth, in (cm)
D = depth of beam, in (cm) — w = total working load, net tons (kgf)

	Greatest safe load, lb		Deflection, in	
Shape of section	Load in middle	Load distributed	Load in middle	Load distributed
Solid rectangle	$\frac{890AD}{L}$	$\frac{1{,}780AD}{L}$	$\frac{wL^3}{32AD^2}$	$\frac{wL^3}{52AD^2}$
Hollow rectangle	$\frac{890(AD - ad)}{L}$	$\frac{1{,}780(AD - ad)}{L}$	$\frac{wL^3}{32(AD^2 - ad^2)}$	$\frac{wL^3}{52(AD^2 - ad^2)}$
Solid cylinder	$\frac{667AD}{L}$	$\frac{1{,}333AD}{L}$	$\frac{wL^3}{24AD^2}$	$\frac{wL^3}{38AD^2}$
Hollow cylinder	$\frac{667(AD - ad)}{L}$	$\frac{1{,}333(AD - ad)}{L}$	$\frac{wL^3}{24(AD^2 - ad^2)}$	$\frac{wL^3}{38(AD^2 - ad^2)}$
I beam	$\frac{1{,}795AD}{L}$	$\frac{3{,}390AD}{L}$	$\frac{wL^3}{58AD^2}$	$\frac{wL^3}{93AD^2}$

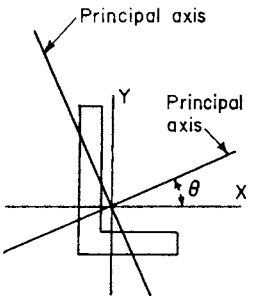

Fig. 5.2.32

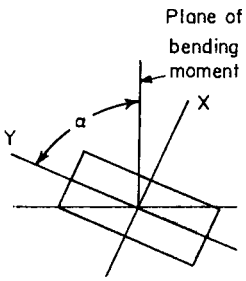

Fig. 5.2.33

In general, it may be stated that when the plane of the bending moment coincides with one of the principal axes, the other principal axis is the neutral axis. This is the ordinary case, in which the ordinary formula for unit stress may be applied. When the plane of the bending moment does not coincide with one of the principal axes, the above formula for oblique loading may be applied.

Internal Moment Beyond the Elastic Limit

Ordinarily, the expression $M = SI/c$ is used for stresses above the elastic limit, in which case S becomes an experimental coefficient S_R, the **modulus of rupture,** and the formula is empirical. The true relation is obtained by applying to the cross section a stress-strain diagram from a tension and compression test, as in Fig. 5.2.34. Figure 5.2.34 shows the side of a beam of depth d under flexure beyond its elastic limit; line 1–1

Table 5.2.5 Coefficients for Correcting Values in Table 5.2.4 for Various Methods of Support and of Loading, Single Span

Conditions of loading	Max relative safe load	Max relative deflection under max relative safe load
Beam supported at ends:		
Load uniformly distributed over span	1.0	1.0
Load concentrated at center of span	½	0.80
Two equal loads symmetrically concentrated	$l/4c$	
Load increasing uniformly to one end	0.974	0.976
Load increasing uniformly to center	¾	0.96
Load decreasing uniformly to center	½	1.08
Beam fixed at one end, cantilever:		
Load uniformly distributed over span	¼	2.40
Load concentrated at end	⅛	3.20
Load increasing uniformly to fixed end	⅜	1.92
Beam continuous over two supports equidistant from ends:		
Load uniformly distributed over span		
1. If distance $a > 0.2071l$	$l^2/(4a^2)$	
2. If distance $a < 0.2071l$	$\frac{l}{l - 4a}$	
3. If distance $a = 0.2071l$	5.83	
Two equal loads concentrated at ends	$l/(4a)$	

NOTE: l = length of beam; c = distance from support to nearest concentrated load; a = distance from support to end of beam.

$r = \frac{h}{\sqrt{6}}$	$\sqrt{\frac{5}{24}}R$		$0.475R$

NOTE: Square, axis same as first rectangle, side = h; $I = h^4/12$; $I/c = h^3/6$; $r = 0.289h$.
Square, diagonal taken as axis: $I = h^4/12$; $I/c = 0.1179h^3$; $r = 0.289h$.

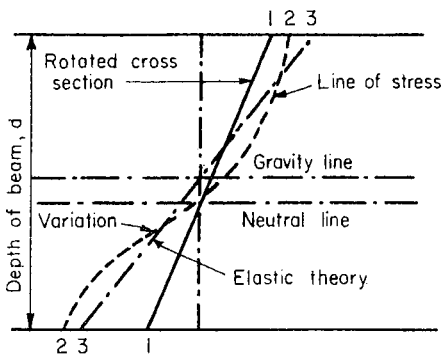

Fig. 5.2.34

shows the distorted cross section; line 3–3, the usual rectilinear relation of stress to strain; and line 2–2, an actual stress-strain diagram, applied to the cross section of the beam, compression above and tension below. The neutral axis is then below the gravity axis. The **outer material** may be expected to develop **greater ultimate strength** than in simple stress, because of the reinforcing action of material nearer the neutral axis that is not yet overstrained. This leads to an **equalization of stress** over the cross section. S_R exceeds the ultimate strength S_M in tension as follows: for cast iron, $S_R = 2S_M$; for sandstone, $S_R = 3S_M$; for concrete, $S_R = 2.2S_M$; for wood (green), $S_R = 2.3S_M$.

In the case of steel I beams, failure begins practically when the elastic limit in the compression flange is reached.

Because of the support of adjoining material, the **elastic limit in flexure** S_p is also greater than in tension, depending upon the relation of breadth to depth of section. For the same breadth, the difference decreases with

increase of height. No difference will occur in the case of an I beam, or with hard materials.

Wide plates will not expand and contract freely, and the value of E will be increased on account of side constraint. As a consequence of lateral contraction of the fibers of the tension side of a beam and lateral swelling of fibers at the compression side, the cross section becomes distorted to a trapezoidal shape, and the neutral axis is at the center of gravity of the trapezoid. Strictly, this shape is one with a curved perimeter, the radius being r_c/μ, where r_c is the radius of curvature of the neutral line of the beam, and μ is Poisson's ratio.

Deflection of Beams

When a beam is subjected to bending, the fibers on one side elongate, while the fibers on the other side shorten (Fig. 5.2.35). These changes in length cause the beam to deflect. All points on the beam except those directly over the support fall below their original position, as shown in Figs. 5.2.31 and 5.2.35.

The **elastic curve** is the curve taken by the neutral axis. The radius of curvature at any point is

$$r_c = EI/M$$

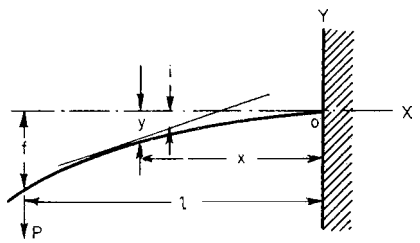

Fig. 5.2.35

A beam bent to a **circular curve** of constant radius has a constant bending moment.

Replacing r_c in the equation by its approximate geometrical value, $1/r_c = d^2y/dx^2$, the fundamental equation from which the elastic curve of a bent beam can be developed and the deflection of any beam obtained is

$$M = EI\,d^2y/dx^2 \quad \text{(approx)}$$

Substituting the value of M, in terms of x, and integrating once, gives the slope of the tangent to the elastic curve of the beam at point x; $\tan i = dy/dx = \int_0^x M\,dx/(EI)$. Since i is usually small, $\tan i = i$,

A number of the sections shown are obsolete and will be encountered mainly in older equipment and/or building structures.

expressed in radians. A second integration gives the vertical deflection of any point of the elastic curve from its original position.

EXAMPLE. In the cantilever beam shown in Fig. 5.2.35, the bending moment at any section $= -P(l - x) = EI\, d^2y/(dx)^2$. Integrate and determine constant by the condition that when $x = 0$, $dy/dx = 0$. Then $EI\, dy/dx = -Plx + \frac{1}{2}Px^2$. Integrate again; and determine constant by the condition that when $x = 0$, $y = 0$. Then $Ely = -\frac{1}{2}Plx^2 + Px^3/6$. This is the equation of the elastic curve. When $x = l$, $y = f = -Pl^3/(3EI)$. In general, the two constants of integration must be determined simultaneously.

Deflection in general, f, may be expressed by the equation $f = Pl^3/(mEI)$, where m is a coefficient. See Tables 5.2.2 and 5.2.4 for values of f for beams of various sections and loadings. For coefficients of deflection of wooden beams and structural steel shapes, see Sec. 12.2.

Since I varies as the cube of the depth, the **stiffness,** or inverse deflection, of various **beams** varies, other factors remaining constant, inversely as the load, inversely as the cube of the span, and directly as the cube of the depth. This deflection is due to bending moment only. In general, however, the bending of beams involves transverse shearing stresses which cause **shearing strains** and thus **add to the total deflection.** The contribution of shearing strain to overall deflection becomes significant only when the beam span is very short. These strains may affect substantially the strength as well as the deflection of beams. When deflection due to transverse shear is to be accounted for, the differential equation of the elastic curve takes the form

$$EI\frac{d^2y}{dx^2} = EI\left(\frac{d^2y_b}{dx^2} + \frac{d^2y_s}{dx^2}\right) = M - \frac{kEI}{AG} \times \frac{d^2M}{dx^2}$$

where k is a factor dependent upon the beam cross section. Sergius Sergev, in "The Effect of Shearing Forces on the Deflection and Strength of Beams" (*Univ. Wash. Eng. Exp. Stn. Bull.* 114) gives $k = 1.2$ for rectangular sections, 10/9 for circular sections, and 2.4 for I beams. He also points out that in the case of a deep, rectangular-section cantilever, carrying a concentrated load at the free end, the deflection due to shear may be up to 3.1 percent of that due to bending moment; if this beam supports a uniformly distributed load, it may be up to 4.1 percent. A deep, simple beam deflection may increase up to 15.6 percent when carrying a uniformly distributed load and up to 12.5 percent when the load is concentrated at midspan.

Design of beams may be based on **strength** (stress) or on **stiffness** if deflection must be limited. Deflection rather than stress becomes the criterion for design, e.g., of machine tools, for which the relative positions of tool and workpiece must be maintained while the cutting loads are applied during operation. Similarly, large steam-turbine shafts supported on two end bearings must maintain alignment and tight critical clearances between the rotating blade assemblies and the stationary stator blades during operation. When more than one beam shares a load, each beam will assume a portion of the load that is proportional to its stiffness. **Superposition** may be used in connection with both stresses and deflections.

EXAMPLE. (Fig. 5.2.36). Two wooden stringers—one *(A)* 8 × 16 in in cross section and 20 ft in span, the other *(B)* 8 in × 8 in × 16 ft—carrying the center load $P_0 = 22{,}000$ lb are required, the load carried by each stringer. The deflections f of the two stringers must be equal. Load on $A = P_1$, and on $B = P_2$. $f = P_1l_1^3/(48EI_1) = P_2l_2^3/(48EI_2)$. Then $P_1/P_2 = l_2^3I_1/(l_1^3I_2) = 4$. $P_0 = P_1 + P_2 = 4P_2 + P_2$, whence $P_2 = 22{,}000/5 = 4{,}400$ lb (1,998 kgf) and $P_1 = 4 \times 4{,}400 = 17{,}600$ lb (7,990 kgf).

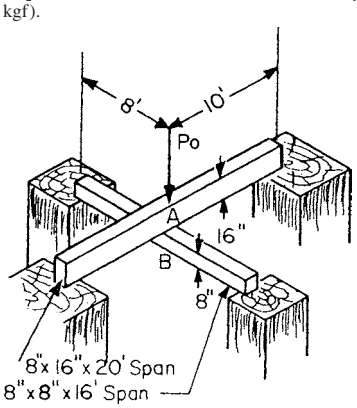

Fig. 5.2.36

Relation between Deflection and Stress

Combine the formula $M = SI/c = Pl/n$, where n is a constant, $P =$ load, and $l =$ span, with formula $f = Pl^3/(mEI)$, where m is a constant. Then

$$f = C''Sl^2/(Ec)$$

where C'' is a new constant $= n/m$. Other factors remaining the same, the **deflection varies directly as the stress and inversely as** E. If the span is

Table 5.2.7

Beam	Load	n	m	C''
Cantilever	Concentrated at end	1	3	1/3
Cantilever	Uniform	2	8	1/4
Simple	Concentrated at center	4	48	1/12
Simple	Uniform	8	384/5	5/48
Fixed ends	Concentrated at center	8	192	1/24
Fixed ends	Uniform	12	384	1/32
One end fixed, one end supported	Concentrated at center	16/3	768/7	7/144
One end fixed, one end supported	Uniform	128/9	185	1/13
Simple	Uniformly varying, maximum at center	6	60	1/10

constant, a shallow beam will submit to greater deformations than a deeper beam without exceeding a safe stress. If depth is constant, a beam of double span will attain a given deflection with only one-quarter the stress. Values of n, m, and C'' are given in Table 5.2.7 (for other values, see Table 5.2.2).

Graphical Relations

Referring to Fig. 5.2.37, the shear V acting at any section is equal to the total load on the right of the section, or

$$V = \int w\,dx$$

Since $w\,dx$ is the product of w, a loading intensity (which is expressed as a vertical height in the load diagram), and dx, an elementary length along the horizontal, evidently $w\,dx$ is the area of a small vertical strip of the **load diagram.** Then $\int w\,dx$ is the summation of all such vertical strips between two indefinite points. Thus, to obtain the shear in any

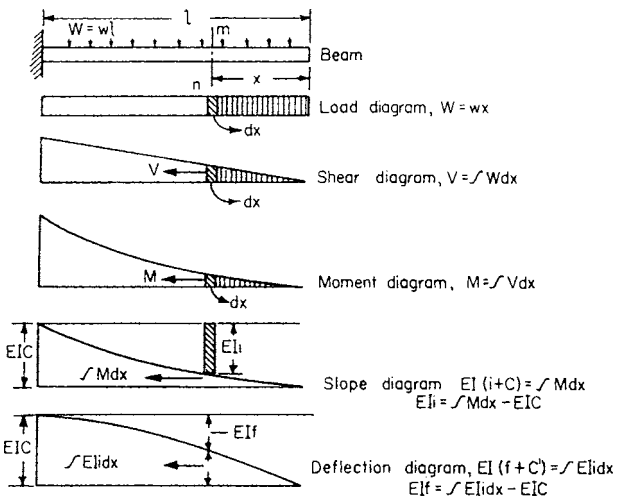

Fig. 5.2.37

section mn, find the area of the load diagram up to that section, and draw a second diagram called the **shear diagram,** any ordinate of which is proportional to the shear, or to the area in the load diagram to the right of mn. Since $V = dM/dx$,

$$\int V dx = M$$

By similar reasoning, a **moment diagram** may be drawn, such that the ordinate at any point is proportional to the area of the shear diagram to the right of that point. Since $M = EI\,d^2f/dx^2$,

$$\int M\,dx = EI(df/dx + C) = EI(i + C)$$

if I is constant. Here C is a constant of integration. Thus i, the slope or grade of the elastic curve at any point, is proportional to the area of the moment diagram $\int M\,dx$ up to that point; and a **slope diagram** may be derived from the moment diagram in the same manner as the moment diagram was derived from the shear diagram.

If I is not constant, draw a new curve whose ordinates are M/I and use these M/I ordinates just as the M ordinates were used in the case where I was constant; that is, $\int (M/I)\,dx = E(i + C)$. The ordinate at any point of the slope curve is thus proportional to the area of the M/I curve to the right of that point. Again, since $iE = E\,df/dx$.

$$\int iE\,dx = \int E\,df = E(f + C)$$

and thus the ordinate f to the elastic curve at any point is proportional to the area of the slope diagram $\int i\,dx$ up to that point. The equilibrium polygon may be used in drawing the **deflection curve** directly from the M/I diagram.

Thus, the five curves of load, shear, moment, slope, and deflection are so related that each curve is derived from the previous one by a process of graphical integration, and with proper regard to scales the deflection is thereby obtained.

The vertical distance from any point A (Fig. 5.2.38) on the elastic curve of a beam to the tangent at any other point B equals the moment of the area of the $M/(EI)$ diagram from A to B about A. This distance, the **tangential deviation** t_{AB}, may be used with the slope-area relation and the geometry of the elastic curve to obtain deflections. These theorems, together with the equilibrium equations, can be used to compute reactions in the case of statically **indeterminate beams.**

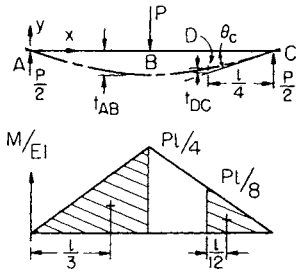

Fig. 5.2.38

EXAMPLE. The deflections of points B and D (Fig. 5.2.38) are

$$y_B = -t_{AB} = \text{moment area}\,\frac{M}{EI}\Big|_A^B$$

$$= -\frac{1}{EI} \times \frac{Pl}{4} \times \frac{l}{4} \times \frac{l}{3} = -\frac{Pl^3}{48EI}$$

$$\theta_c = \nabla\theta\Big|_B^C = \text{area}\,\frac{M}{EI}\Big|_B^C = \frac{1}{EI} \times \frac{Pl}{4} \times \frac{l}{4} = \frac{Pl^2}{16EI}$$

$$y_D = -\left(\theta_c \times \frac{l}{4} - t_{DC}\right)$$

$$= -\frac{Pl^2}{16EI} \times \frac{l}{4} \times \frac{l}{EI} \times \frac{Pl}{8} \times \frac{l}{8} \times \frac{l}{12} = -\frac{11Pl^3}{768EI}$$

Resilience of Beams

The external work of a load gradually applied to a beam, and which increases from zero to P, is $\frac{1}{2}Pf$ and equals the **resilience** U. But, from the formulas $P = nSI/(cl)$ and $f = nSl^2/(mcE)$, where n and m are constants that depend upon loading and supports, S = fiber stress, c = distance from neutral axis to outer fiber, and l = length of span. Substitute for P and f, and

$$U = \frac{n^2}{m}\left(\frac{k}{c}\right)^2 \frac{S^2 V}{2E}$$

where k is the radius of gyration and V the volume of the beam. For values of U, see Table 5.2.1.

The resilience of beams of similar cross section at a given stress is proportional to their volumes. The **internal resilience,** or the elastic deformation energy in the material of a beam in a length x is dU, and

$$U = \tfrac{1}{2}\int M^2\, dx/(EI) = \tfrac{1}{2}\int M\, di$$

where M is the moment at any point x, and di is the angle between the tangents to the elastic curve at the ends of dx. The values of resilience and deflection in special cases are easily developed from this equation.

Rolling Loads

Rolling or **moving loads** are those loads which may change their position on a beam. Figure 5.2.39 represents a beam with two equal concentrated moving loads, such as two wheels on a crane girder, or the wheels of a

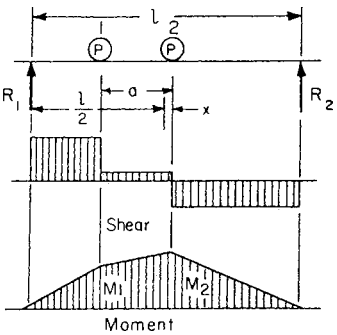

Fig. 5.2.39

truck on a bridge. Since the maximum moment occurs where the shear is zero, it is evident from the shear diagram that the maximum moment will occur under a wheel. $x < a/2$:

$$R_1 = P\left(1 - \frac{2x}{l} + \frac{a}{l}\right)$$

$$M_2 = \frac{Pl}{2}\left(1 - \frac{a}{l} + \frac{2x}{l}\frac{a}{l} - \frac{4x^2}{l^2}\right)$$

$$R_2 = P\left(1 + \frac{2x}{l} - \frac{a}{l}\right)$$

$$M_1 = \frac{Pl}{2}\left(1 - \frac{a}{l} - \frac{2a^2}{l^2} + \frac{2x}{l}\frac{3a}{l} - \frac{4x^2}{l^2}\right)$$

M_2 max when $x = \frac{1}{4}a$

M_1 max when $x = \frac{3}{4}a$

$$M_{\max} = \frac{Pl}{2}\left(1 - \frac{a}{2l}\right)^2 = \frac{P}{2l}\left(l - \frac{a}{2}\right)^2$$

EXAMPLE. Two wheel loads of 3,000 lb each, spaced on 5-ft centers, move on a span of l = 15 ft, x = 1.25 ft, and R_2 = 2,500 lb. $\therefore M_{\max} = M_2 = 2{,}500 \times 6.25$ $(1{,}135 \times 1.90) = 15{,}600$ lb · ft (2,159 kgf · m).

Figure 5.2.40 shows the condition when two equal loads are equally distant on opposite sides of the center. The moment is equal under the two loads.

If the **two moving loads** are **of unequal weight,** the condition for **maximum moment** is that the maximum moment will occur under the heavy wheel when the center of the beam bisects the distance between the resultant of the loads and the heavy wheel. Figure 5.2.41 shows the position and the shear and moment diagrams.

When **several wheel loads** constituting a system occur, the several suspected wheels must be examined in turn to determine which will cause the greatest moment. The **position for the greatest moment** that can occur under a given wheel is, as stated, when the center of the span bisects the distance between the wheel in question and the resultant of all the loads then on the span. The **position for maximum shear** at the support will be when one wheel is passing off the span.

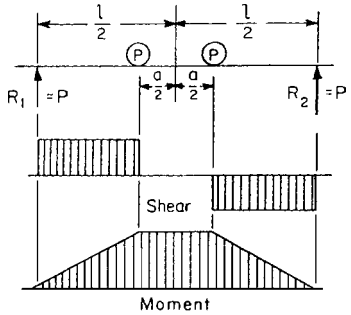

Fig. 5.2.40

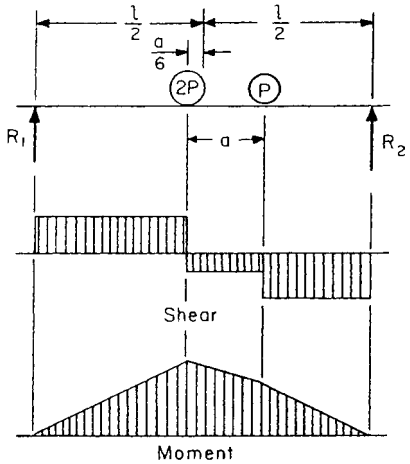

Fig. 5.2.41

Constrained Beams

Constrained beams are those so held or "built in" at one or both ends that the tangent to the elastic curve remains fixed in direction. These beams are held at the ends in such a manner as to allow free horizontal motion, as illustrated by Fig. 5.2.42. A constrained beam is stiffer than a simple beam of the same material, because of the modification of the moment by an end resisting moment. Figure 5.2.43 shows the two most common cases of constrained beams. See also Table 5.2.2.

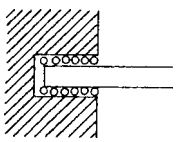

Fig. 5.2.42

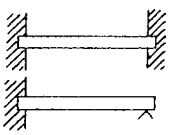

Fig. 5.2.43

Continuous Beams

A continuous beam is one resting upon several supports which may or may not be in the same horizontal plane. The general discussion for

beams holds for continuous beams. $S_v A = V$, $SI/c = M$, and $d^2f/dx^2 = M/(EI)$. The **shear** at any section is equal to the algebraic sum of the components parallel to the section of all external forces on either side of the section. The bending moment at any section is equal to the moment of all external forces on either side of the section. The relations stated above between shear and moment diagrams hold true for continuous beams. The bending moment at any section is equal to the bending moment at any other section, plus the shear at that section times its arm, plus the product of all the intervening external forces times their respective arms. To illustrate (Fig. 5.2.44):

$$V_x = R_1 + R_2 + R_3 - P_1 - P_2 - P_3$$
$$M_x = R_1(l_1 + l_2 + x) + R_2(l_2 + x) + R_3x - P_1(l_2 + c + x) - P_2(b + x) - P_3a$$
$$M_x = M_3 + V_3x - P_3a$$

Table 5.2.8 gives the value of the moment at the various supports of a uniformly loaded continuous beam over equal spans, and it also gives the values of the shears on each side of the supports. Note that the shear is of opposite sign on either side of the supports and that the sum of the two shears is equal to the reaction.

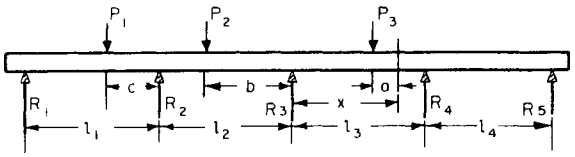

Fig. 5.2.44

Figure 5.2.45 shows the relation between the moment and shear diagrams for a uniformly loaded continuous beam of four equal spans (see Table 5.2.8). Table 5.2.8 also gives the **maximum bending moment** which will occur **between supports,** and in addition the position of this moment and the points of inflection (see Fig. 5.2.46).

Figure 5.2.46 shows the values of the functions for a uniformly loaded continuous beam resting on three equal spans with four supports.

Continuous beams are **stronger and much stiffer than simple beams.** However, a small, unequal subsidence of piers will cause serious

	Rectangle: width (b) constant, depth (y) variable	Elevation: ellipse Plan: rectangle	$\frac{x^2}{\left(\frac{l}{2}\right)^2} + \frac{y^2}{\frac{3Pl}{4bS_s}} = 1$ $h = \sqrt{\frac{3Pl}{4bS_s}}$ Deflection at O: $f = \frac{1}{64}\frac{Pl^3}{EI}$ $= \frac{3}{16}\frac{P}{bE}\left(\frac{l}{h}\right)^3$

changes in sign and magnitude of the bending stresses, reactions, and shears.

Maxwell's Theorem When a number of loads rest upon a beam, the deflection at any point is equal to the sum of the deflections at this point due to each of the loads taken separately. Maxwell's theorem states that if unit loads rest upon a beam at two points A and B, the deflection at A due to the unit load at B equals the deflection at B due to the unit load at A.

Castigliano's theorem states that the deflection of the point of application of an external force acting on a beam is equal to the partial derivative of the work of deformation with respect to this force. Thus, if P is the force, f the deflection, and U the work of deformation, which equals the resilience,

$$dU/dP = f$$

According to the **principle of least work,** the deformation of any structure takes place in such a manner that the work of deformation is a minimum.

Similarly, angular rotation of a point in a structure θ can be determined by $dU/dM_t = \theta$, where M_t is the bending or torsional moment.

In applying Castigliano's theorem, the strain energy must be expressed as a function of the load. If the structure is subjected to combination of loads, for example, axial force N, bending moment M, shearing force V, and torsional moment M_t, the strain energy is

$$U = \int \frac{N^2\,dx}{2EA} + \int \frac{M^2\,dx}{2EI} + \int \frac{f_s V^2\,dx}{2GA} + \int \frac{M_t^2\,dx}{2GJ}$$

Note that the last integral is valid only for a circular cross section. Using Castigliano's theorem, the displacement f is given by

$$f = \frac{1}{EA}\int N\frac{\partial N}{\partial P}dx + \frac{1}{EI}\int M\frac{\partial M}{\partial P}dx + \frac{1}{GA}\int f_s V\frac{\partial V}{\partial P}dx + \frac{1}{GJ}\int M_t\frac{\partial M_t}{\partial P}dx$$

Beams of Uniform Strength

Beams of uniform strength vary in section so that the unit stress S remains constant, the I/c varies as M. For **rectangular beams,** of breadth b and depth d, $I/c = bd^2/6$; and $M = Sbd^2/6$. Thus, for a cantilever beam of rectangular cross section, under a load P, $Px = Sbd^2/6$. If b is constant, d^2 varies with x, and the profile of the shape of the beam will be a parabola, as Fig. 5.2.47. If d is constant, b will vary as x and the beam will be triangular in plan, as shown in Fig. 5.2.48.

Shear at the end of a beam necessitates a modification of the forms determined above. The area required to resist shear will be P/S_v in a cantilever and R/S_v in a simple beam. The dotted extensions in Figs. 5.2.47 and 5.2.48 show the changes necessary to enable these cantilevers to resist shear. The extra material and cost of fabrication, however, make many of the forms impractical.

Table 5.2.9 shows some of the simple **sections of uniform strength.** In none of these, however, is shear taken into account.

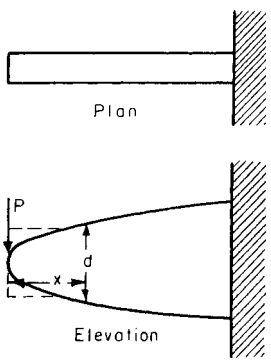

Fig. 5.2.47

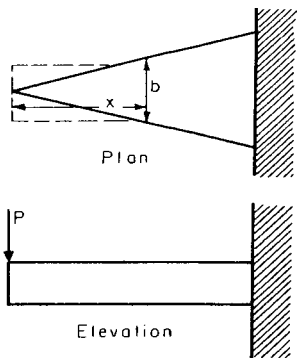

Fig. 5.2.48

TORSION

Under torsion, a bar (Fig. 5.2.49) is twisted by a couple of magnitude Pp. Elements of the surface becomes helices of angle d, and a radius rotates through an angle θ in a length l, both d and θ being expressed in radians. S_v = shearing unit stress at distance r from center; I_p = *polar moment of inertia;* G = shearing modulus of elasticity. It is assumed that the cross sections remain plane surfaces. The strain on the cross section is wholly tangential, and is zero at the center of the section. Note that $ld = r\theta$.

In the case of a **circular cross section,** the stress S_v increases directly as the distance of the strained element from the center.

The polar moment of inertia I_p for any section may be obtained from $I_p = I_1 + I_2$, where I_1 and I_2 are the rectangular moments of inertia of the section about any two lines at right angles to each other, through the center of gravity.

The **external twisting moment** M_t is balanced by the internal resisting moment.

For strength, $M_t = S_v I_p/r$.

For stiffness, $M_t = aGI_p/l$.

The torsional resilience $U = \frac{1}{2}Ppa = S_v^2 I_p l/(2r^2 G) = a^2 G I_p/(2l)$.

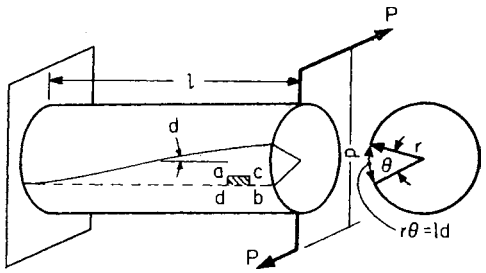

Fig. 5.2.49

The state of stress on an element taken from the surface of the shaft, as in Fig. 5.2.50, is pure shear. Pure tension exists at right angles to one 45° helix and pure compression at right angles to the opposite helix.

Reduced **formulas for shafts of various sections** are given in Table 5.2.11. When the ratio of shaft length to the largest lateral dimension in the cross section is less than approximately 2, the **end effects** may drastically affect the torsional stresses calculated.

Failure under torsion in brittle materials is a tensile failure at right angles to a helical element on the surface. Plastic materials twist off squarely. Fibrous materials separate in long strips.

Torsion of Noncircular Sections When a section is not circular, the unit stress no longer varies directly as the distance from the center. Cross sections become warped, and the greatest unit stress usually occurs at a point on the perimeter of the cross section *nearest* the axis of twist; thus, there is no stress at the corners of square and rectangular sections. The analyses become complex for noncircular sections, and the methods for solution of design problems using them most often admit only of approximations.

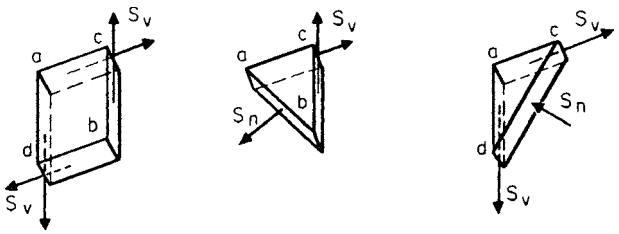

Fig. 5.2.50

Torsion problems have been solved for many different noncircular cross sections by utilizing the **membrane analogy,** due to Prandtl, which makes use of the fact that the mathematical treatment of a twisted bar is governed by the same equations as for a membrane stretched over a hole which has the same shape as the bar and then inflated. The resulting three-dimensional surface provides the following: (1) The torque transmitted is proportional to twice the volume under the inflated membrane, and (2) the shear stress at any point is proportional to the slope of the curve measured perpendicular to that slope. In recent years, several other mathematical techniques have become widely used, especially with the aid of faster computational methods available from electronic computers.

By using **finite-difference methods,** the differential operators of the governing equations are replaced with difference operators which are related to the desired unknown values at a gridwork of points in the outline of the cross section being investigated.

The **finite-element method,** commonly referred to as **FEM,** deals with a spatial approximation of a complex shape which is then analyzed to determine deformations, stresses, etc. By using FEM, the exact structure is replaced with a set of simple structural elements interconnected at a finite number of nodes. The governing equations for the approximate structure can be solved exactly. Note that inasmuch as there is an exact solution for an approximate structure, the end result must be viewed, and the results thereof used, as approximate solutions to the real structure.

Using a finite-difference approach to Poisson's partial differential equation, which defines the stress functions for solid and hollow shafts with generalized contours, along with Prandl's membrane analogy, Isakower has developed a series of practical design charts (ARRADCOMMISD Manual UN 80-5, January 1981, Department of the Army). Dimensionless charts and tables for transmitted torque and maximum shearing stress have been generated. Information for circular shafts with rectangular and circular keyways, external splines and milled flats, as well as rectangular and X-shaped torsion bars, is presented.

Assuming the stress distribution from the point of maximum stress to the corner to be parabolic, Bach derived the approximate expression, $S_s M = 9M_t/(2b^2h)$ for a rectangular section, b by h, where $h > b$. For closer results, the shearing stresses for a **rectangular section** (Fig. 5.2.51) may be expressed $S_A = M_t/(\alpha_A b^2 h)$ and $S_B = M_t/(\alpha_B b^2 h)$. The angle of twist for these shafts is $\theta = M_t l/(\beta G b^3 h)$. The factors α_A, α_B, and β are functions of the ratio h/b and are given in Table 5.2.10.

In the case of **composite sections,** such as a tee or angle, the torque that can be resisted is $M_t = G\,\theta \Sigma \beta h b^3$; the summation applies to each of the rectangles into which the section can be divided. The maximum stress occurs on the component rectangle having the largest b value. It is computed from

$$S_A = M_t \beta_A b_A / (\alpha_A \Sigma \beta h b^3)$$

Torque, deflection, and work relations for some additional sections are given in Table 5.2.11.

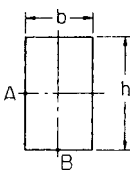

Fig. 5.2.51

COLUMNS

Members subjected to direct compression can be grouped into three classes. **Compression blocks** are so short (slenderness ratios below 30) that bending of member is unlikely. At the other limit, columns so slender that bending is primary, are the **long columns** defined by Euler's theory. The intermediate columns, quite common in practice, are called **short columns.**

Long columns and the more slender short columns usually fail by **buckling** when the **critical load** is reached. This is a matter of **instability;** that is, the column may continue to yield and deflect even though the load is not increased above critical. The **slenderness ratio** is the unsupported length divided by the least radius of gyration, parallel to which it can bend.

Long columns are handled by **Euler's column formula,**

$$P_{cr} = n\pi^2 EI/l^2 = n\pi^2 EA/(l/r)^2$$

The **coefficient** n accounts for **end conditions.** When the column is pivoted at both ends, $n = 1$; when one end is fixed and other rounded, $n = 2$; when both are fixed, $n = 4$; and when one end is fixed with the other free, $n = ¼$. The slenderness ratio that separates long columns from short ones depends upon the modulus of elasticity and the yield strength of the column material. When Euler's formula results in $(P_{cr}/A) > S_y$, strength rather than buckling causes failure, and the column ceases to be long. In round numbers, this **critical slenderness ratio** falls between 120 and 150. Table 5.2.12 gives additional facts concerning long columns.

Short Columns The stress in a short column may be considered partly due to compression and partly due to bending. A theoretical equation has not been derived. Empirical, though rational, expressions are, in general, based on the assumption that the permissible stress must be reduced below that which could be permitted were it due to compression only. The manner in which this reduction is made determines the type of equation as well as the slenderness ratio beyond which the **equation does not apply.** Figure 5.2.52 illustrates the situation. Some typical formulas are given in Table 5.2.13.

EAMPLE. A machine member unsupported for a length of 15 in has a square cross section 0.5 in on a side. It is to be subjected to compression. What maximum safe load can be applied centrally, according to the AISC formula? At the computed load, what size section (also square) would be needed, if it were to be designed according to the AREA formula?

$$l/r = 15/0.5/\sqrt{12} = 104 \qquad \therefore \text{short column}$$

$$P/A = 17{,}000 - 0.485(104)^2 = 11{,}730$$

or $$P = 0.25 \times 11{,}730 = 2{,}940 \text{ lb } (1{,}335 \text{ kgf})$$

and $$\frac{2{,}940}{a^2} \le 15{,}000 - 50\left(\frac{15la}{\sqrt{12}}\right) = 15{,}000 - \frac{2{,}600}{a}$$

thus $$a^2 - 0.173a - 0.196 = 0 \quad \text{or} \quad a = 0.536 \text{ in } (1.36 \text{ cm})$$

Combined Flexure and Longitudinal Force Figure 5.2.53 shows a bar under flexure due to transverse and longitudinal loads. The maximum fiber stress S is made up of S_0, due to the direct action of load P, and S_b, due to the entire bending moment M. M is the algebraic sum of two bending moments, M_1 due to longitudinal load (+ for compression and − for tension), and M_2 due to transverse load. $M = M_2 \pm M_1$. Here $M_1 = Pf$ and $f = CS_b l^2/(Ec)$.

* S_{cr} = theoretical maximum, c = end fixity coefficient,
$c = 2$, both ends pivoted; $c = 2.86$, one pivoted, other fixed;
$c = 4$, both ends fixed; $c = 1$, one end fixed, one end free.
† e is initial eccentricity at which load is applied to center of column cross section.

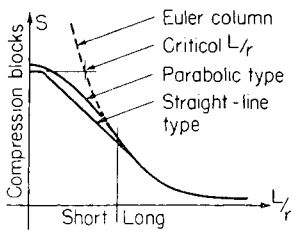

Fig. 5.2.52

FOR THE CASE OF LONGITUDINAL COMPRESSION. $S_b I/c = M_2 + CPS_b l^2/(Eo)$, or $S_b = M_2 c(I - CPl^2/E)$. The maximum stress is $S = S_b + S_0$ compression. The constant C for the case of Fig. 5.2.53 is derived from the equations $P'l/4 = S_b I/c$ and $f = P'l^3/(48EI)$. Solving for f; $f = 1/12\ S_b l^2/(Ec)$, or $C = 1/12$. For a beam supported at the ends and uniformly loaded, $C = 5/48$. Other cases can be similarly calculated.

FOR THE CASE OF LONGITUDINAL TENSION. $M = M_2 - Pf$, and $S_b = M_2 c/(I + CPl^2/E)$. The maximum stress is $S = S_b + S_0$, tension.

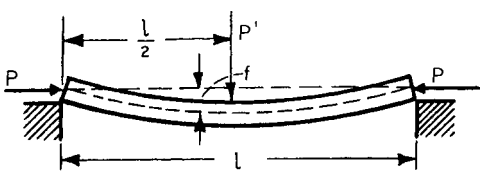

Fig. 5.2.53

ECCENTRIC LOADS

When **short blocks** are **loaded eccentrically** in compression or in tension, i.e., not through the center of gravity (cg), a combination of axial and bending stress results. The maximum unit stress S_M is the algebraic sum of these two unit stresses.

In Fig. 5.2.54 a load P acts in a line of symmetry at the distance e from cg; r = radius of gyration. The unit stresses are (1) S_c, due to P, as

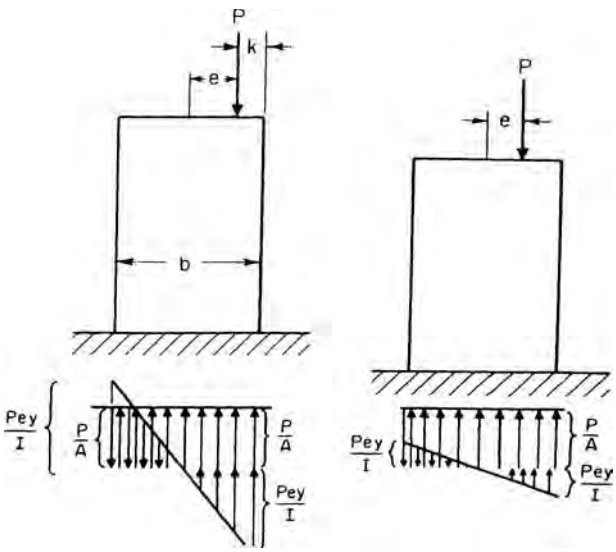

Fig. 5.2.54

if it acted through cg, and (2) S_b, due to the bending moment of P acting with a leverage of e about cg. Thus unit stress S at any point y is

$$S = S_c \pm S_b$$
$$= P/A \pm Pey/I$$
$$= S_c(1 \pm et/r^2)$$

y is positive for points on the same side of cg as P, and negative on the opposite side. For a **rectangular cross section** of width b, the maximum stress $S_M = S_c\ (1 + 6e/b)$. When P is outside the middle third of width b and is a compressive load, tensile stresses occur.

For **a circular cross section** of diameter d, $S_M = S_c(1 + 8e/d)$. The stress due to the weight of the solid will modify these relations.

NOTE. In these formulas e is measured from the gravity axis, and gives tension when e is greater than one-sixth the width (measured in the same direction as e), for rectangular sections; and when greater than one-eighth the diameter for solid circular sections.

If, as in certain classes of masonry construction, the **material cannot withstand tensile stress** and thus no tension can occur, the center of moments (Fig. 5.2.55) is taken at the center of stress. For a **rectangular section,** P acts at distance k from the nearest edge. Length under compression $= 3k$, and $S_M = \frac{2}{3}P/(hk)$. For a **circular section,** $S_M = [0.372 + 0.056(k/r)]P/k\sqrt{rk}$, where r = radius and k = distance of P from circumference. For a **circular ring,** S = average compressive stress on cross section produced by P; e = eccentricity of P; z = length of diameter under compression (Fig. 5.2.56). Values of z/r and of the ratio of S_{max} to average S are given in Tables 5.2.14 and 5.2.15.

CHIMNEY PROBLEM. Weight of chimney = 563,000 lb; e = 1.56 ft; OD of chimney = 10 ft 8 in; ID = 6 ft 6 ½ in. Overturning moment = Pe = 878,000 ft· lb, r_1/r = 0.6. e/r = 0.29. This gives $z/r > 2$. Therefore, the entire area of the base is under compression. Area under compression = 55.8 ft^2; I = 546; S = 563,000/55.8 ± (878,000 × 5.33)/546 = 18,700 (max) and 1,500 (min) lb compression per ft^2. From Table 5.2.15, by interpolation, $S_{max}/S_{av} = 1.85$. ∴ S_{max} = (563,000/55.8) × 1.85 = 18,685 lb/ft^2 (91,313 kgf/m^2).

The **kern** is the area around the center of gravity of a cross section within which any load applied will produce stress of only one sign throughout the entire cross section. Outside the kern, a load produces stresses of different sign. Figure 5.2.57 shows kerns (shaded) for various sections.

For **a circular ring,** the radius of the kern $r = D[1 + (d/D)^2]/8$.

For a **hollow square** (H and h = lengths of outer and inner sides), the kern is a square similar to Fig. 5.2.57*a*, where

$$r_{\min} = \frac{H}{6}\frac{1}{\sqrt{2}}\left[1 + \left(\frac{h}{H}\right)^2\right] = 0.1179H\left[1 + \left(\frac{h}{H}\right)^2\right]$$

For a **hollow octagon** R_a and R_i = radii of circles circumscribing the outer and inner sides; thickness of wall = $0.9239(R_a - R_i)$, the kern is an octagon similar to Fig. 5.2.57*c*, where $0.2256R$ becomes $0.2256R_a[1 + (R_i/R_a)^2]$.

CURVED BEAMS

The application of the flexure formula for a straight beam to the case of a curved beam results in error. When all "fibers" of a member have the same center of curvature, the **concentric** or common type of curved beam exists (see Fig. 5.2.58). Such a beam is defined by the Winkler-Bach theory. The stress at a point y units from the centroidal axis is

$$S = \frac{M}{AR}\left[1 + \frac{y}{Z(R + y)}\right]$$

M is the bending moment, positive when it increases curvature; Y is positive when measured toward the convex side; A is the cross-sectional area; R is the radius of the centroidal axis; Z **is a cross-section property** defined by

$$Z = -\frac{1}{A}\int \frac{y}{R + y}\,dA$$

Analytical expressions for Z of certain sections are given in Table 5.2.16. Also Z can be found by **graphical** integration methods (see any advanced strength book). The **neutral surface** shifts toward the center of curvature, or inside fiber, an amount equal to $e = ZR/(Z + 1)$. The Winkler-Bach theory, though practically satisfactory, disregards radial stresses as well as lateral deformations and assumes pure bending. The **maximum stress** occurring on the inside fiber is $S = Mh_i/(AeR_i)$, while that on the outside fiber is $S = Mh_0/(AeR_0)$.

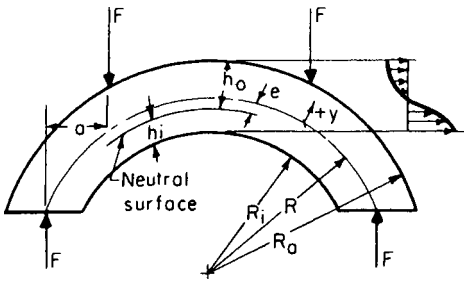

Fig. 5.2.58

EXAMPLE. A split steel ring of rectangular cross section is subjected to a diametral force of 1,000 lb as shown in Fig. 5.2.59*a*. Compute the stress at the point 0.5 in from the outside fiber on plane *mm*. Also compute the maximum stress.

$$Z = -1 + \frac{R}{h}\ln\frac{R + C}{R - C}$$
$$= -1 + \frac{10}{4}\ln\frac{10 + 2}{10 - 2} = 0.0133$$
$$S_{1.5} = \frac{M}{AR}\left[1 + \frac{y}{Z(R + y)}\right] + \frac{F}{A}$$
$$= \frac{-1{,}000 \times 10}{8 \times 10}\left[1 + \frac{1.5}{0.0133(10 + 1.5)}\right] + \frac{1{,}000}{8}$$
$$= -1{,}250 + 125 = -1{,}125 \text{ lb/in}^2 \text{ (compr.)} (79 \text{ kgf/cm}^2)$$

$$S_M = \frac{-1{,}000}{8}\left[1 + \frac{-2}{0.0133(10-2)}\right] + \frac{1{,}000}{8}$$

$$= 2{,}230 + 125 = 2{,}335 \text{ lb/in}^2 \text{ (166 kfg/cm}^2\text{)}$$

or $$e = \frac{ZR}{Z+1} = \frac{0.0133 \times 10}{0.0133 + 1} = 0.131$$

and $$S_M = \frac{Mh_i}{AeR_i} + \frac{F}{A} = \frac{1{,}000 \times 10 \times 1.87}{8 \times 0.131 \times 8} + \frac{1{,}000}{8}$$

$$= 2{,}355 \text{ lb/in}^2 \text{ (166 kgf/cm}^2\text{)}$$

The **deflection** in curved beams can be computed by means of the moment-area theory. If the origin of axes is taken at the point whose deflection is wanted, it can be shown that the component displacements in the x and y directions are

$$\Delta_x = \int_0^s \frac{My\,ds}{EI} \quad \text{and} \quad \Delta_y = \int_0^s \frac{Mx\,ds}{EI}$$

The resultant deflection is then equal to $\Delta_0 = \sqrt{\Delta_x^2 + \Delta_y^2}$ in the direction defined by $\tan\theta = \Delta_y/\Delta_x$. Deflections can also be found conveniently by use of **Castigliano's theorem.** It states that in an elastic system the displacement in the direction of a force (or couple) and due to that force (or couple) is the partial derivative of the strain energy with respect to the force (or couple). Stated mathematically, $\Delta_z = \partial U/\partial F_z$. If a force does not exist at the point and/or in the direction desired, a dummy force may be applied. This force must then be eliminated by equating it to zero at the end.

EXAMPLE. A quadrant of radius R is fixed at one end as shown in Fig. 5.2.59*b*. The force F is applied in the radial direction at the free end B. Find the deflection of B.

By moment area:

$$y = R\sin\theta \qquad x = R(1-\cos\theta)$$

$$ds = R\,d\theta \qquad m = FR\sin\theta$$

$${}_B\Delta_x = \frac{FR^3}{EI}\int_0^{\pi/2}\sin^2\theta\,d\theta = \frac{\pi FR^3}{4EI}$$

$${}_B\Delta_y = \frac{FR^3}{EI}\int_0^{\pi/2}\sin\theta(1-\cos\theta)\,d\theta = -\frac{FR^3}{2EI}$$

and $$\Delta_B = \frac{FR}{2EI}\sqrt{1 + \frac{\pi^2}{4}}$$

at $$\theta_x = \tan^{-1}\left(-\frac{FR^3}{2EI} \times \frac{4EI}{\pi FR^3}\right) = \tan^{-1}\frac{2}{\pi} = 32.5°$$

By Castigliano:

$${}_B\Delta_x = \frac{\partial U}{\partial F} = \frac{\partial}{\partial F_x}\int_0^{\pi/2}\frac{F^2R^3}{2EI}\sin^2\theta\,d\theta = \frac{\pi FR^3}{4EI}$$

$${}_B\Delta_y = \frac{\partial U}{\partial F_y} = \frac{\partial}{\partial F_y}\int_0^{\pi/2}\frac{[FR\sin\theta - F_yR(1-\cos\theta)]^2R\,d\theta}{2EI}$$

$$= -\frac{FR^3}{2EI}$$

The F_y, assumed downward, is equated to zero, after the integration and differentiation are performed to find ${}_B\Delta_y$. The remainder of the computation is exactly as in the moment-area method.

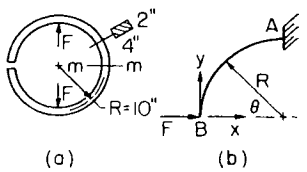

Fig. 5.2.59

Eccentrically Curved Beams These beams (Fig. 5.2.60) are bounded by arcs having different centers of curvature. In addition, it is possible for either radius to be the larger one. The one in which the section depth shortens as the central section is approached may be called the **arch beam.** When the central section is the largest, the beam is of the crescent type. **Crescent I** denotes the beam of larger outside radius and **crescent II** of larger inside radius. The stress at the **central section** of such beams may be found from $S = KMC/I$. In the case of rectangular cross section, the equation becomes $S = 6KM/(bh^2)$ where M is the bending moment, b is the width of the beam section, and h its height. The **stress factors** K for the **inner boundary,** established from photoelastic data, are given in Table 5.2.17. The outside radius is denoted by R_o and the inside by R_i. The geometry of crescent beams is such that the stress can be larger in **off-center sections.** The stress at the central section determined above must then be multiplied by the **position factor** k, given in Table 5.2.18. As in the concentric beam, the **neutral surface** shifts slightly toward the inner boundary (see Vidosic, Curved Beams with Eccentric Boundaries, *Trans. ASME,* 79, pp., 1317–1321).

Table 5.2.16 Analytical Expressions for *Z*

Section	Expression	Section	Expression
	$Z = -1 + \frac{R}{h}\ln\frac{R+C}{R-C}$		$Z = -1 + \frac{R}{A}\left[t\ln(R+C_1) + (b-t)\ln(R-C_3) - b\ln(R-C_3)\right]$ $A = tC_1 - (b-t)C_3 + bC_2$
	$Z = -1 + 2\left(\frac{R}{r}\right)\left[\frac{R}{r} - \sqrt{\left(\frac{R}{r}\right)^2 - 1}\right]$		$Z = -1 + \frac{R}{A}\left[b\ln\frac{R+C_2}{R-C_2} + (t-b)\ln\frac{R+C_1}{R-C_1}\right]$ $A = 2[(t-b)C_1 + bC_2]$

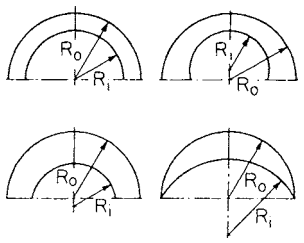

Fig. 5.2.60

Table 5.2.17 Stress Factors for Inner Boundary at Central Section (See Fig. 5.2.60)

1. For the arch-type beams

(a) $K = 0.834 + 1.504\dfrac{h}{R_o + R_i}$ if $\dfrac{R_o + R_i}{h} < 5.$

(b) $K = 0.899 + 1.181\dfrac{h}{R_o + R_i}$ if $5 < \dfrac{R_o + R_i}{h} < 10.$

(c) In the case of larger section ratios use the equivalent beam solution.

2. For the crescent I-type beams

(a) $K = 0.570 + 1.536\dfrac{h}{R_o + R_i}$ if $\dfrac{R_o + R_i}{h} < 2.$

(b) $K = 0.959 + 0.769\dfrac{h}{R_o + R_i}$ if $2 < \dfrac{R_o + R_i}{h} < 20.$

(c) $K = 1.092\left(\dfrac{h}{R_o + R_i}\right)^{0.0298}$ if $\dfrac{R_o + R_i}{h} > 20.$

3. For the crescent II-type beams

(a) $K = 0.897 + 1.098\dfrac{h}{R_o + R_i}$ if $\dfrac{R_o + R_i}{h} < 8.$

(b) $K = 1.119\left(\dfrac{h}{R_o + R_i}\right)^{0.0378}$ if $8 < \dfrac{R_o + R_i}{h} > 20.$

(c) $K = 1.081\left(\dfrac{h}{R_o + R_i}\right)^{0.0270}$ if $\dfrac{R_o + R_i}{h} > 20.$

Table 5.2.18 Crescent-Beam Position Stress Factors (See Fig. 5.2.60)

Angle θ, deg	k	
	Inner	Outer
10	$1 + 0.055H/h$	$1 + 0.03H/h$
20	$1 + 0.164H/h$	$1 + 0.10H/h$
30	$1 + 0.365H/h$	$1 + 0.25H/h$
40	$1 + 0.567H/h$	$1 + 0.467H/h$
50	$1.521 - \dfrac{(0.5171 - 1.382H/h)^{1/2}}{1.382}$	$1 + 0.733H/h$
60	$1.756 - \dfrac{(0.2416 - 0.6506H/h)^{1/2}}{0.6506}$	$1 + 1.123H/h$
70	$2.070 - \dfrac{(0.4817 - 1.298H/h)^{1/2}}{0.6492}$	$1 + 1.70H/h$
80	$2.531 - \dfrac{(0.2939 - 0.7084H/h)^{1/2}}{0.3542}$	$1 + 2.383H/h$
90		$1 + 3.933H/h$

NOTE: All formulas are valid for $0 < H/h \leq 0.325$. Formulas for the inner boundary, except for 40 deg, may be used to $H/h \leq 0.36$. H = distance between centers.

IMPACT

A force or stress is considered **suddenly applied** when the duration of load application is less than one-half the **fundamental natural period** of vibration of the member upon which the force acts. Under impact, a compression wave propagates through the member at a velocity $c = \sqrt{E/\rho}$, where ρ is the mass density. As this compression wave travels back and forth by reflection from one end of the bar to the other, a maximum stress is produced which is many times larger than what it would be statically. An exact determination of this stress is most difficult. However, if conservation of kinetic and strain energies is applied, the **impact stress** is found to be

$$S' = S\sqrt{\frac{W}{W_b}\left(\frac{3W}{3W + W_b}\right)}$$

The weight of the striking mass is here denoted by W, that of the struck bar by W_b, while S is the static stress, W/A (A is the cross-sectional area of the bar). Above is the case of **sudden impact.** When the ratio W/W_b is small, the stress computed by the above equation may be erroneous. A better solution of this problem may result from

$$S' = S + S\sqrt{\frac{W}{W_b} + \frac{2}{3}}$$

If a weight W falls a distance h before striking a bar of mass W_b, energy conservation will yield the relation

$$S' = S\left(1 + \sqrt{1 + \frac{2h}{e} \times \frac{3W}{3W + W_b}}\right)$$

The elongation $e = \varepsilon l = SI/E$. When the striking mass W is assumed rigid, the elasticity factor is taken equal to 1. Thus the equation becomes

$$S' = S(1 + \sqrt{1 + 2h/e})$$

If, in addition, h is taken equal to zero (sudden impact), the radical equals 1, and so the stress becomes $S' = 2S$. Since Hooke's law is applicable, the relations

$$e' = e(1 + \sqrt{1 + 2h/e}) \qquad \text{and} \qquad e' = 2e$$

are also true for the same conditions.

The expression may be converted, by using $v^2 = 2gh$, to

$$S' = S[1 + \sqrt{1 + v^2/(eg)}]$$

This might be called the **energy impact** form. If the **natural frequency** f_n of the bar is used, the stress equation is

$$S' = S(1 + \sqrt{1 + 0.204hf_n^2})$$

In general, the **maximum impact stress** in a **beam** and a **shaft** can be approximated from the simplified falling-weight equation. It is necessary, though, to substitute the maximum **deflection** y for e, in the case of beams, and for the **angle of twist** θ in the case of shafts. Of course $S = Mc/I$ and $M_t c/J$, respectively. Thus

$$S' = S\left[1 + \sqrt{1 + \frac{2h}{y(\text{or } \theta)}}\right]$$

For a more exact solution, elastic yield in each member must be considered. The theory then yields

$$S' = S\left[1 + \sqrt{1 + \frac{2h}{y}\left(\frac{35W}{35W + 17W_b}\right)}\right]$$

for a **simply supported beam** struck in the middle by a weight W.

THEORY OF ELASTICITY

For loaded members in which the stress distribution cannot be estimated by elementary strength-of-material methods, the more advanced mathematical principles of the **theory of elasticity** must be applied. When this is not possible, experimental stress analysis has to be used. Because of the complexity of solution, only some of the more practical problems have been solved by the theory of elasticity. The more general concepts and methods are presented.

Two kinds of forces may act on a body. **Surface forces** are distributed over the surface as the result of, for instance, the pressure of one body on another. Forces due to gravity, inertia, magnetism, etc., which act over the entire volume of a body, are called **body forces.** Both surface and body forces can be best handled if resolved into three orthogonal components. Surface forces are thus designated $\overline{X}$, $\overline{Y}$, and $\overline{Z}$, while body forces are labeled X, Y, and Z.

In general, there exists a normal stress σ and a shearing stress τ at each point of a loaded member. It is convenient to deal with components of each of these stresses on each of six orthogonal planes that bound the point element. Thus there are at each point **six stress components,** σ_x, σ_y, σ_z, $\tau_{yx} = \tau_{xy}$, $\tau_{xz} = \tau_{zx}$, and $\tau_{yz} = \tau_{zy}$. Similarly, if the normal unit strain is designated by the letter ε and shearing unit strain by γ, the **six components of strain** are defined by

$$\varepsilon_x = \partial u/\partial x \qquad \varepsilon_y = \partial v/\partial y \qquad \varepsilon_z = \partial w/\partial z$$

$$\gamma_{xy} = \partial u/\partial y + \partial v/\partial x \qquad \gamma_{yz} = \partial v/\partial z + \partial w/\partial y$$

and $$\gamma_{xz} = \partial u/\partial z + \partial w/\partial x$$

The elastic **displacements** of particles on the body in the x, y, and z directions are identified as the u, v, and w **components,** respectively.

Since metals have the usually assumed elastic as well as isotropic properties, Hooke's law holds. Therefore, the interrelationships between stress and strain can easily be obtained.

$$\varepsilon_x = \frac{1}{E}[\sigma_x - \mu(\sigma_y + \sigma_z)]$$

$$\varepsilon_y = \frac{1}{E}[\sigma_y - \mu(\sigma_x + \sigma_z)]$$

$$\varepsilon_z = \frac{1}{E}[\sigma_z - \mu(\sigma_x + \sigma_y)]$$

$$\gamma_{xy} = \tau_{xy}/G \qquad \gamma_{xz} = \tau_{xz}/G$$

and $$\gamma_{yz} = \tau_{yz}/G$$

The general case of strain can be obtained by superposing the elongation strains upon the shearing strains.

Problems depending upon theories of elasticity are considerably simplified if the stresses are all parallel to one plane or if all deformations occur in planes perpendicular to the length of the member. The first case is one of **plane stress,** as when a thin plate of uniform thickness is subjected to central, boundary forces parallel to the plane of the plate. The second is a case of **plane strain,** such as a gate subjected to hydrostatic pressure, the intensity of which does not vary along the gate's length. All particles therefore displace at right angles to the length, and so cross sections remain plane. In plane-stress problems, three of the six stress components vanish, thus leaving only σ_x, σ_y, and τ_{xy}. Similarly, in plane strain, only ε_x, ε_y, and γ_{xy} will not equal zero; thus the same three stresses σ_x, σ_y, and τ_{xy} remain to be considered. Plane problems can thus be represented by the element shown in Fig. 5.2.61. Equilibrium considerations applied to this particle result in the **differential equations of equilibrium** which reduce to

$$\frac{\partial \sigma_x}{\partial x} + \frac{\partial \tau_{xy}}{\partial y} + X = 0$$

and $$\frac{\partial \sigma_y}{\partial y} + \frac{\partial \tau_{xy}}{\partial x} + Y = 0$$

Since the two differential equations of equilibrium are insufficient to find the three stresses, a third equation must be used. This is the **compatibility equation** relating the three strain components. It is

$$\frac{\partial^2 \varepsilon_x}{\partial y^2} + \frac{\partial^2 \varepsilon_y}{\partial x^2} = \frac{\partial^2 \gamma_{xy}}{\partial x\, \partial y}$$

If strains are expressed in terms of the stresses, the compatibility equation becomes

$$\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}\right)(\sigma_x + \sigma_y) = 0$$

Now, in any **two-dimensional** problem, the compatibility equation along with the differential equilibrium equations must be simultaneously solved for the three unknown stresses. This is accomplished using **stress functions,** which permit the integration and satisfy boundary conditions in each particular situation.

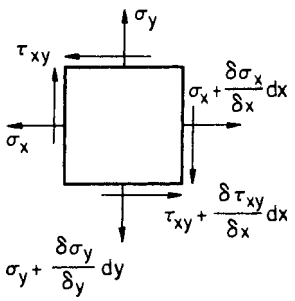

Fig. 5.2.61

In **three-dimensional** problems, the third dimension must be considered. This results in three differential equations of equilibrium, as well as three compatibility equations. The six stress components can thus be found. The complexity involved in the solution of these equations is such, however, that only a few special cases have been solved.

In certain problems, such as rotating circular disks, **polar coordinates** become more convenient. In such cases, the stress components in a two-dimensional field are the **radial stress** σ_r, the **tangential stress** σ_θ, and the **shearing stress** $\tau_{r\theta}$. In terms of these stresses the **polar differential equations** become

$$\frac{\partial \sigma_r}{\partial r} + \frac{1}{r}\frac{\partial \tau_{r\theta}}{\partial \theta} + \frac{\sigma_r - \sigma_\theta}{r} + R = 0$$

and $$\frac{1}{r}\frac{\partial \sigma_\theta}{\partial \theta} + \frac{\partial \tau_{r\theta}}{\partial r} + \frac{2\tau_{r\theta}}{r} = 0$$

The body force per unit volume is represented by R. The **compatibility equation** in polar coordinates is

$$\left(\frac{\partial^2}{\partial r^2} + \frac{1}{r}\frac{\partial}{\partial r} + \frac{1}{r^2}\frac{\partial^2}{\partial \theta^2}\right)\left(\frac{\partial^2 \phi}{\partial r^2} + \frac{1}{r}\frac{\partial \phi}{\partial r} + \frac{1}{r^2}\frac{\partial^2 \phi}{\partial \theta^2}\right) = 0$$

ϕ is again a stress function of r and θ that will provide a solution of the differential equations and satisfy boundary conditions. As an example, the exact solution of a **simply supported beam** carrying a uniformly distributed load w yields

$$\sigma_x = \frac{w}{2I}(I^2 - x^2)y + \frac{w}{2I}\left(\frac{2y^3}{3} - \frac{2c^2 y}{5}\right)$$

The origin of coordinates is at the center of the beam, $2c$ is the beam depth, and $2l$ is the span length. Thus the maximum stress at $x = 0$ and $y = c$ is $\sigma_x = \dfrac{wl^2 c}{2I} + \dfrac{2}{15}\dfrac{wc^3}{I}$. The first term represents the stress as obtained by the elementary flexure theory; the second is a correction. The second term becomes negligible when c is small compared to l.

The important case of a **flat plate** of unit width with a **circular hole** of diameter $2a$ at its center, subjected to a uniform tensile load, has been solved using polar coordinates. If S is the uniform stress at some distance from the hole, r is measured from the center of the hole, and θ is the angle of r with respect to the longitudinal axis of the member, the stresses are

$$\sigma_r = \frac{S}{2}\left(1 - \frac{a^2}{r^2}\right) + \frac{S}{2}\left(1 + \frac{3a^4}{r^4} - \frac{4a^2}{r^2}\right)\cos 2\theta$$

$$\sigma_\theta = \frac{S}{2}\left(1 + \frac{a^2}{r^2}\right) - \frac{S}{2}\left(1 + \frac{3a^4}{r^4}\right)\cos 2\theta$$

$$\tau_r\theta = -\frac{S}{2}\left(1 - \frac{3a^4}{r^4} + \frac{2a^2}{r^2}\right)\sin 2\theta$$

CYLINDERS AND SPHERES

A thin-wall cylinder has a wall thickness such that the assumption of constant stress across the wall results in negligible error. Cylinders having internal-diameter-to-thickness (D/t) ratios greater than 10 are usually considered thin-walled. Boilers, drums, tanks, and pipes are often treated as such. Equilibrium equations reveal the circumferential, or hoop, stress to be $S = pr/t$ under an internal pressure p (see Fig. 5.2.62). If the cylinder is closed at the ends, a longitudinal stress of $pr/(2t)$ is developed. The tensile stress developed in a thin hollow sphere subjected to internal pressure is also $pr/(2t)$.

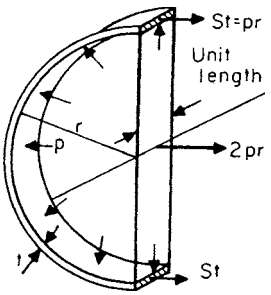

Fig. 5.2.62

When thin-walled cylinders, such as vacuum tanks and submarines, are subjected to **external pressure, collapse** becomes the mode of failure. The shell is assumed perfectly round and of uniform thickness, the material obeys Hooke's law, the radial stress is negligible, and the normal stress distribution is linear. Other, lesser assumptions are also made. Using the theory of elasticity, R. G. Sturm (*Univ. Ill. Eng. Exp. Stn. Bull.*, no 12, Nov. 11, 1941) derived the **collapsing pressure** as

$$W_c = KE\left(\frac{t}{D}\right)^3 \qquad \text{lb/in}^2$$

The factor K, a numerical coefficient, depends upon the L/R and D/t ratios (D is outside-shell diameter), the kind of end support, and whether pressure is applied radially only, or at the ends as well. Figures 5.2.63 to 5.2.66, reproduced from the bulletin, supply the K values. N on these charts indicates the number of lobes into which the shell collapses. These values are for materials having Poisson's ratio $\mu = 0.3$. It may also be pointed out that in the case of long cylinders (infinitely long, theoretically) the value of K approaches $2/(1 - \mu^2)$.

When the **cylinder** is **stiffened with rings,** the shell may be assumed to be divided into a series of shorter shells, equal in length to the ring spacing. The previous equation can then be applied to a ring-to-ring length of cylinder. However, the flexural rigidity of the combined stiffener and shell EI_c necessary to withstand the pressure is $EI_c = W_s D^3 L_s/24$. W_s is the pressure, L_s the length between rings, and I_c the combined moment of inertia of the ring and that portion of the shell assumed acting with the ring.

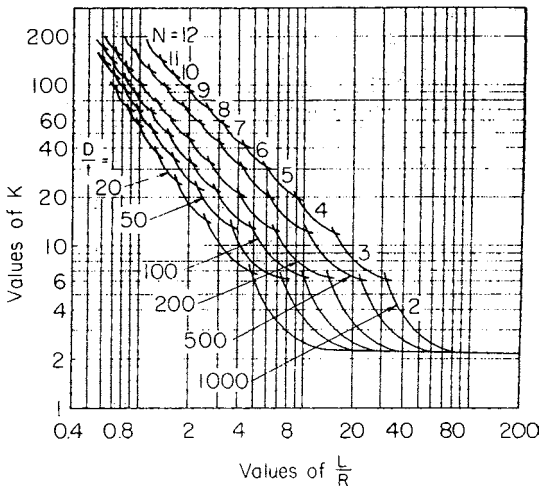

Fig. 5.2.63 Radial external pressure with simply supported edges.

In some instances, cylinders collapse only after a stress in excess of the elastic limit has been reached; that is, **plastic range** stresses are present. In such cases the same equation applies, but the modulus of elasticity must be modified.

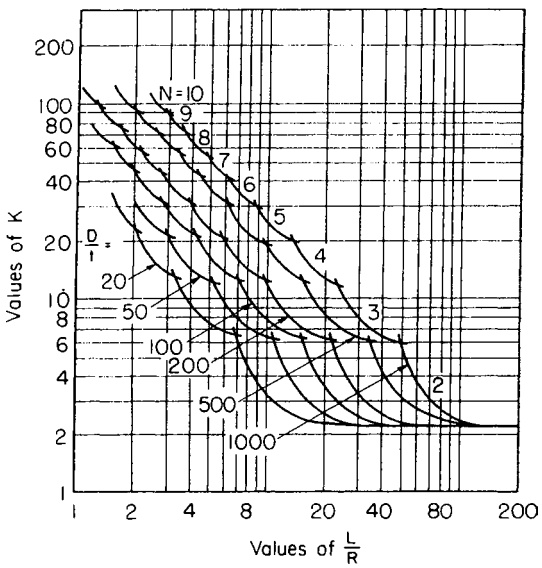

Fig. 5.2.64 Radial external pressure with fixed edges.

When the average stress S_a is less than the proportional limit S_p, and the maximum stress (direct, plus bending) is S, the modified modulus

$$E' = E\left[1 - \frac{1}{4}\left(\frac{S - S_l}{S_u - S_a}\right)^2\right]$$

S_u is the modulus of rupture. When the average stress is larger than the proportional limit, the modified modulus is taken as the tangent at the average stress.

In **thick-walled cylinders** (Fig. 5.2.67a) the circumferential, hoop, or tangential stress S_t is not uniform. In addition a radial stress S_r is present. When equilibrium is applied to the annulus taken out of Fig. 5.2.67a and

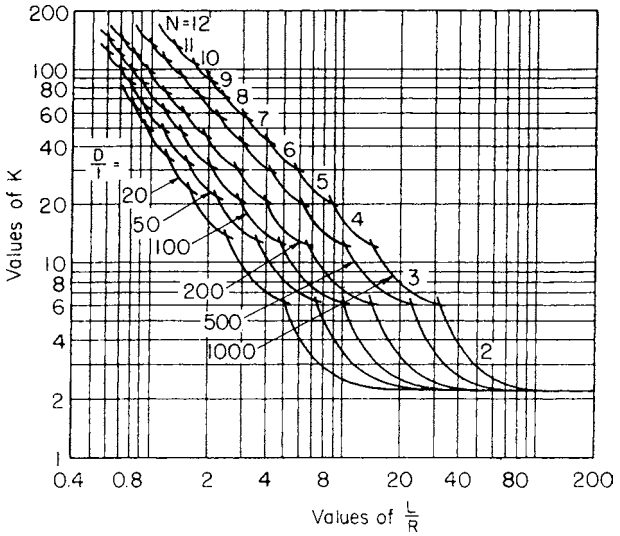

Fig. 5.2.65 Radial and end external pressure with simply supported edges.

shown in Fig. 5.2.67*b* and the equation is integrated, the general tangential and radial stress relations, called the **Lamé** equations, are derived.

$$S_t = \frac{r_1^2 p_1 - r_2^2 p_2 + (p_1 - p_2) r_1^2 r_2^2 / r^2}{r_2^2 - r_1^2}$$

and

$$S_r = \frac{r_1^2 p_1 - r_2^2 p_2 - (p_1 - p_2) r_1^2 r_2^2 / r^2}{r_2^2 - r_1^2}$$

When the external pressure $p_2 = 0$, the equations reduce to

$$S_t = \frac{r_1^2 p_1}{r_2^2 - r_1^2}\left(1 + \frac{r_2^2}{r^2}\right)$$

and

$$S_r = \frac{r_1^2 p_1}{r_2^2 - r_1^2}\left(1 + \frac{r_2^2}{r^2}\right)$$

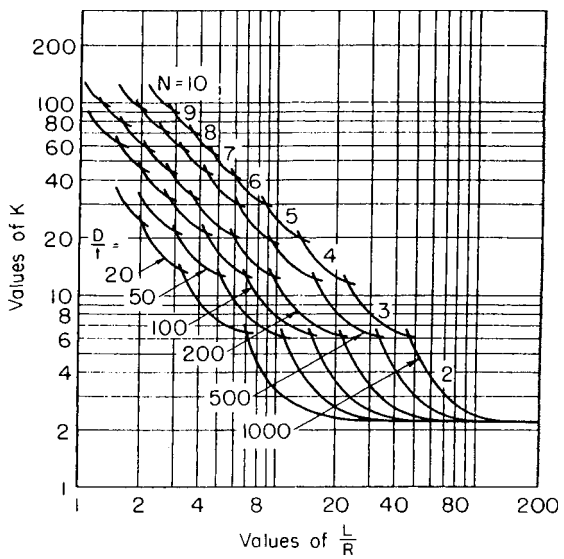

Fig. 5.2.66 Radial and end external pressure with fixed edges.

At the inner boundary the tangential elongation ε_t is equal to

$$\varepsilon_t = (S_t - \mu S_r)/E$$

The increase in the bore radius Δr_1 resulting therefrom is

$$\Delta r_1 = \frac{r_1 p_1}{E_h}\left(\frac{1 + r_1^2/r_2^2}{1 - r_1^2/r_2^2} + \mu\right)$$

Similarly a solid shaft of r radius under external pressure p_2 will have its radius decreased by the amount

$$\Delta r = -\frac{r p_2}{E_s}(1 - \mu)$$

In the case of a **press or shrink fit,** $p_1 = p_2 = p$. The sum of Δr_1 and Δr_1 absolute is the radial interference; twice this sum is the **diametral interference** Δ or

$$\Delta = 2 r_1 p\left[\frac{1}{E_h}\left(\frac{1 + r_1^2/r_2^2}{1 - r_1^2/r_2^2} + \mu\right) + \frac{1 - \mu}{E_s}\right]$$

If the hub and shaft materials are the same, $E_h = E_s = E$, and

$$\Delta = \frac{4 r_1 r_2^2 p}{E(r_2^2 - r_1^2)}$$

If the equation is solved for p and this value is substituted in Lamé's equation, the maximum tangential stress on the inner surface of the hub is found to be

$$S_t = \frac{E\Delta}{4 r_1 r_2^2}(r_2^2 + r_1^2)$$

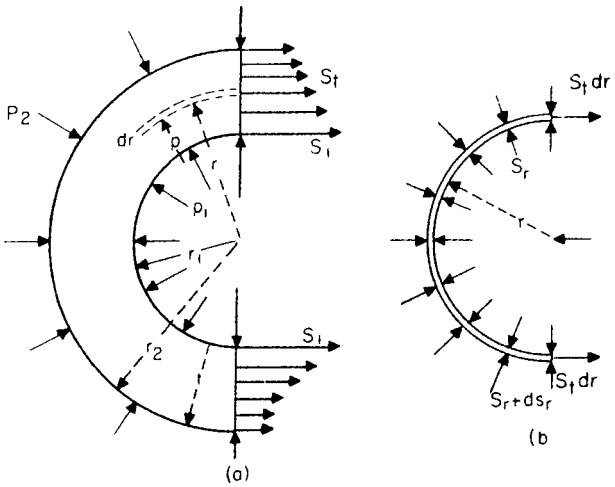

Fig. 5.2.67

EXAMPLE. The barrel of a field gun has an outside diameter of 9 in and a bore of 4.7 in. An internal pressure of 16,000 lb/in^2 is developed during firing. What maximum stress occurs in the barrel? An investigation of Lamé's equations for internal pressure reveals the maximum stress to be the tangential one on the inner surface. Thus,

$$S_t = p_1 \frac{r_1^2 + r_2^2}{r_2^2 - r_1^2} = \frac{16{,}000(2.35^2 + 4.5^2)}{4.5^2 - 2.35^2}$$

$$= 28{,}000 \text{ lb/in}^2 \text{ (1,972 kgf/cm}^2\text{)}$$

Oval Hollow Cylinders In Fig. 5.2.68, let a and b be the semiminor and semimajor axes. The bending moments at A and C will then be

$$M_0 = pa^2/2 - pI_x/(2S) - pI_y/(2S)$$
$$M_1 = M_0 - p(a^2 - b^2)/2$$

where I_x and I_y are the moments of inertia of the arc AC about the x and y axes, respectively. The **bending moment at any point** will be

$$M = M_0 - pa^2/2 + px^2/2 + py^2/2$$

Thick Hollow Spheres With an **internal pressure** p, where $p < T/0.65$.

$$r_2 = r_1[(T + 0.4p)/(T - 0.65p)]^{1/3}$$

The maximum tensile stress is on the inner surface, in the direction of the circumference. With an **external pressure** p, where $p < T/1.05$,

$$r_2 = r_1[T/(T - 1.05p)]^{1/3}$$

In both cases T is the true stress.

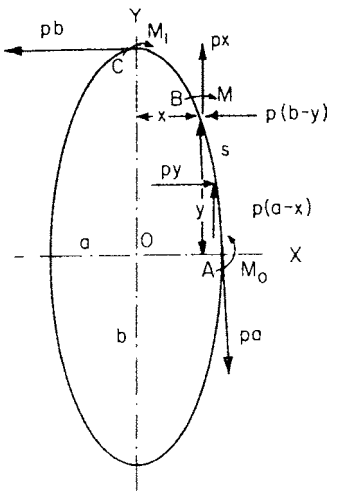

Fig. 5.2.68

PRESSURE BETWEEN BODIES WITH CURVED SURFACES (CONTACT STRESSES)

(See Hertz, "Gesammelte Werke," vol. 1, pp. 159 *et seq.*, Barth.)

Two Spheres The radius A of the compressed area is obtained from the formula $A^3 = 0.68P(c_1+c_2)/(1/r_1 + 1/r_2)$, in which P is the compressing force, c_1 and c_2 (= $1/E_1$ and $1/E_2$) are reciprocals of the respective moduli of elasticity, and r_1 and r_2 are the radii. (Reciprocal of Poisson's ratio is assumed to be $n = 10/3$.) The **greatest contact pressure** in the middle of the compressed surface will be $S_{max} = 1.5(P/\pi A^2)$, and

$$S^3_{max} = 0.235P(1/r_1 + 1/r_2)^2/(c_1 + c_2)^2$$

The **total deformation** of the two spheres will be Y, which is obtained from

$$Y^3 = 0.46P^2(c_1 + c_2)^2(1/r_1 + 1/r_2)$$

For $c_1 = c_2 = 1/E$, i.e., two spheres with the same modulus of elasticity, it follows that $A^3 = 1.36P/E(1/r_1 + 1/r_2)$, $S^3_{max} = 0.059PE^2(1/r_1 + 1/r_2)^2$, and $Y^3 = 1.84P^2(1/r_1 + 1/r_2)/E^2$. If the radii of these spheres are also equal, $A^3 = 0.68Pr/E = 0.34Pd/E$; $S^3_{max} = 0.235PE^2/r^2 = 0.94PE^2/d^2$; and $Y^3 = 3.68P^2/(E^2r) = 7.36P^2/(E^2d)$.

Sphere and Flat Plate In this case $r_1 = r$ and $r_2 = \infty$, and the above formulas become $A^3 = 0.68Pr(c_1 + c_2) = 1.36Pr/E$, and

$$S^3_{max} = 0.235P/[r^2(c_1 + c_2)^2] = 0.059PE^2/r^2$$

$$Y^3 = 0.46P^2(c_1 + c_2)^2/r = 1.84P^2/(E^2r)$$

Two Cylinders The width b of the rectangular pressure surface is obtained from $(b/4)^2 = 0.29P(c_1 + c_2)/l[(1/r_1 + (1/r_2)]$, where r_1 and r_2 are the radii, and l the length

$$S^2_{max} = [4P/(\pi bl)]^2 = 0.35P(1/r_1 + 1/r_2)/l(c_1 + c_2)]$$

For cylinders with the same moduli of elasticity, $c_1 = c_2 = 1/E$, and $(b/4)^2 = 0.58P/El[(1/r_1) + (1/r_2)]$; and $S^2_{max} = 0.175PE(1/r_1 + 1/r_2)/l$. When $r_1 = r_2 = r$, $(b/4)^2 = 0.29Pr/(El)$, and $S^2_{max} = 0.35PE/(lr)$.

Cylinder and Flat Plate Here $r_1 = r$, $r_2 = \infty$, and the above formulas reduce to $(b/4)^2 = 0.29Pr(c_1 + c_2)/l = 0.58Pr/(El)$, and

$$S^2_{max} = 0.35P/[lr(c_1 + c_2)] = 0.175PE/(lr)$$

For application to ball and roller bearings and to gear teeth, see Sec. 8.

FLAT PLATES

The analysis of flat plates subjected to **lateral loads** is very involved because plates bend in all vertical planes. Strict mathematical derivations have therefore been accomplished only in some special cases. Most of the available formulas contain some amount of rational empiricism. Plates may be classified as (1) **thick plates,** in which transverse shear is important; (2) **average-thickness plates,** in which flexure stress predominates; (3) **thin plates,** which depend in part upon direct tension; and (4) **membranes,** which are subject to direct tension only. However, exact lines of demarcation do not exist.

The flat-plate formulas given apply primarily to symmetrically loaded **average-thickness plates** of constant thickness. They are valid only if the maximum deflection is small relative to the plate thickness; usually, $y \le 0.4t$. In the mathematical analyses, allowance for stress redistribution, because of slight local yielding, is usually not made. Since this yielding, especially in ductile materials, is beneficial, the formulas generally err on the side of safety. Certain cases of symmetrically loaded **circular and rectangular plates** are presented in Figs. 5.2.69 and 5.2.70. The maximum stresses are calculated from

$$S_M = k\frac{wR^2}{t^2} \qquad S_M = k\frac{P}{t^2} \qquad \text{or} \qquad S_M = k\frac{C}{t^2}$$

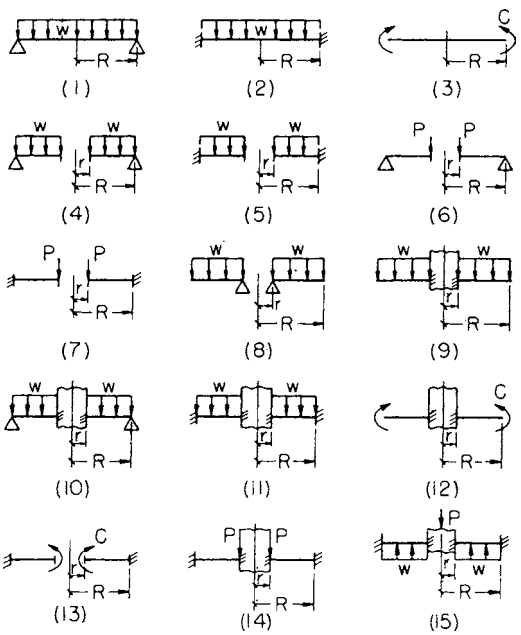

Fig. 5.2.69 Circular plates. Cases (4), (5), (6), (7), (8), and (13) have central hole of radius r; cases (9), (10), (11), (12), (14), and (15) have a central piston of radius r to which the plate is fixed.

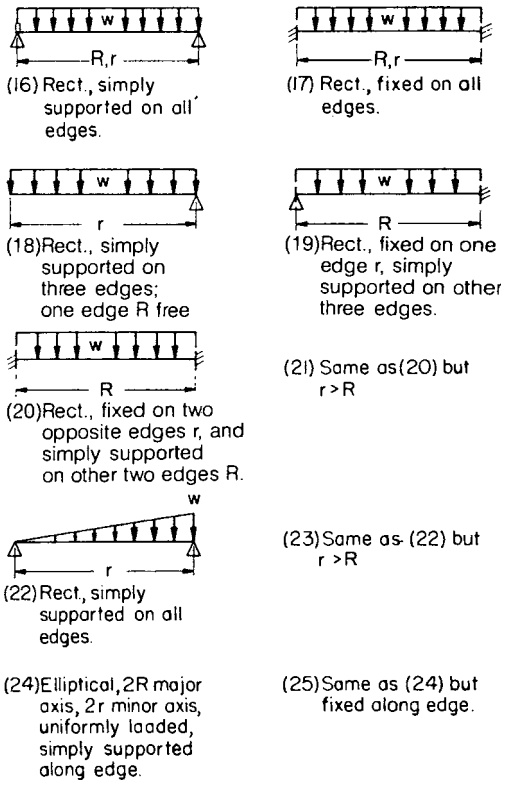

Fig. 5.2.70 Rectangular and elliptical plates. [R is the longer dimension except in cases (21) and (23).]

The first equation is for a uniformly distributed load w, lb/in^2; the second supports a concentrated load P, lb; and the third a couple C, per unit length, uniformly distributed along the edge. Combinations of these loadings may be treated by superposition. The factors k and k_1 are given in Tables 5.2.19 and 5.2.20; R is the radius of circular plates or one side of rectangular plates, and t is the plate thickness. [In Figs. 5.2.69 and 5.2.70, r = radius of hole or piston for circular plates and r = smaller side of rectangular plates.]

The **maximum deflection** for the same cases is given by

$$y_M = k_1\frac{wR^4}{Et^3} \qquad y_M = k_1\frac{PR^2}{Et^3} \qquad \text{and} \qquad y_M = k_1\frac{CR^2}{Et^3}$$

The factors k_1 are also given in the tables. For additional information, including shells, refer to ASME Handbook, "Metals Engineering: Design," McGraw-Hill.

THEORIES OF FAILURE

Material properties are usually determined from tests in which specimens are subjected to **simple stresses** under static or fluctuating loads. The attempt to apply these data to **bi- or triaxial stress fields** has resulted in the proposal of various theories of failure. Figure 5.2.71 shows the principal stresses on a triaxially stressed element. It is assumed, for simplicity. that $S_1 > S_2 > S_3$. Compressive stresses are negative.

1. **Maximum-stress theory** (Rankine) assumes failure occurs when the largest principal stress reaches the yield stress in a tension (or compression) specimen. That is, $S_1 = \pm S_y$.
2. **Maximum-shear theory** (Coulomb) assumes yielding (failure) occurs when the maximum shearing stress equals that in a simple tension (or compression) specimen at yield. Mathematically, $S_1 - S_3 = \pm S_y$.
3. **Maximum-strain-energy theory** (Beltrami) assumes failure occurs when the energy absorbed per unit volume equals the strain energy per unit volume in a tension (or compression) specimen at yield. Mathematically, $S_1^2 + S_2^2 + S_3^2 - 2\mu(S_1S_2 + S_2S_3 + S_3S_1) = S_y^2$.
4. **Maximum-distortion-energy theory** (Huber, von Mises, Hencky) assumes yielding occurs when the distortion energy equals that in simple tension at yield. The distortion energy, that portion of the total energy which causes distortion rather than volume change, is

$$U_d = \frac{1+\mu}{3E}(S_1^2 + S_2^2 + S_3^2 - S_1S_2 - S_2S_3 - S_3S_1)$$

Thus failure is defined by

$$S_1^2 + S_2^2 + S_3^2 - (S_1S_2 + S_2S_3 + S_3S_1) = S_y^2$$

5. **Maximum-strain theory** (Saint-Venant) claims failure occurs when the maximum strain equals the strain in simple tension at yield or $S_1 - \mu(S_2 + S_3) = S_y$.

* Length ratio is r/R in cases 21 and 23.

6. **Internal-friction theory** (Mohr). When the ultimate strengths in tension and compression are the same, this theory reduces to that of maximum shear. For principal stresses of opposite sign, failure is defined by $S_1 - (S_{uc}/S_u)\, S_2 = -S_{uc}$; if the signs are the same $S_1 = S_u$ or $-S_{uc}$, where S_{uc} is the ultimate strength in compression. If the principal stresses are both either tension or compression, then the larger one, say S_1, must equal S_u when S_1 is tension or S_{uc} when S_1 is compression.

A **graphical representation** of the first four theories applied to a biaxial stress field is presented in Fig. 5.2.72. Stresses outside the bounding lines in the case of each theory mean failure (yield or fracture). A comparison with experimental data proves the distortion-energy theory (4) best for ductile materials of equal tension-compression properties. When these properties are unequal, the internal friction theory (6) appears best. In practice, judging by some accepted codes, the maximum-shear theory (2) is generally used for ductile materials, and the maximum-stress theory (1) for brittle materials.

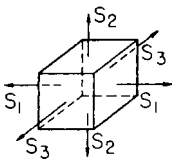

Fig. 5.2.71

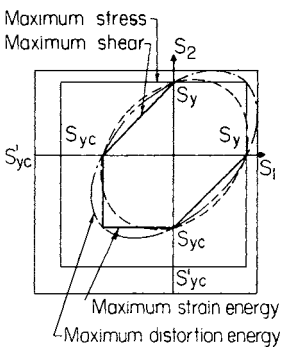

Fig. 5.2.72

Fatigue failures cannot be related, theoretically, to elastic strength and thus to the theories described. However, experimental results justify this, at least to a limited extent. Therefore, the theory evaluation given above holds for **fluctuating stresses,** provided that principal stresses at the maximum load are used and the **endurance strength** in simple bending is substituted for the yield strength.

EXAMPLE. A steel shaft, 4 in in diameter, is subjected to a bending moment of 120,000 in · lb, as well as a torque. If the yield strength in tension is 40,000 lb/in^2, what maximum torque can be applied under the (1) maximum-shear theory and (2) the distortion-energy theory?

$$S_x = \frac{M_c}{I} = \frac{120{,}000 \times 2}{12.55} = 19{,}100 \text{ lb/in}^2 \qquad S_{xy} = \frac{TC}{J} = \frac{T \times 2}{25.1} = 0.0798T$$

and
$$S_{M,m} = \frac{S_x}{2} \pm \sqrt{\left(\frac{S_x}{2}\right)^2 + S_{xy}^2}$$

$$S_M - S_m = S_y \quad \text{or} \quad 2\sqrt{\left(\frac{19{,}100}{2}\right)^2 + (0.0798T)^2} = 40{,}000 \tag{1}$$

or
$$T = 221{,}000 \text{ in} \cdot \text{lb} (254{,}150 \text{ cm} \cdot \text{kgf})$$

$$S_M^2 + S_m^2 - S_M S_m = S_y^2 \tag{2}$$

substituting and simplifying,

$$(9{,}550)^2 + 3\sqrt{\left(\frac{19{,}100}{2}\right)^2 + (0.0798T)^2} = (40{,}000)^2$$

or
$$T = 255{,}000 \text{ in} \cdot \text{lb} (293{,}250 \text{ cm} \cdot \text{kgf})$$

PLASTICITY

The reaction of materials to stress and strain in the plastic range is not fully defined. However, some concepts and theories have been proposed.

Ideally, a **purely elastic material** is one complying explicitly with Hooke's law. In a **viscous material,** the shearing stress is proportional to the shearing strain. The **purely plastic material** yields indefinitely, but only after reaching a certain stress. Combinations of these are the **elastoviscous** and the **elastoplastic** materials.

Engineering materials are not ideal, but usually contain some of the elastoplastic characteristics. The **total strain** ε_t is the sum of the **elastic strain** ε_o plus the **plastic strain** ε_p, as shown in Fig. 5.2.73, where the stress-strain curve is approximated by two straight lines. The **natural strain,** which is at the same time the total strain, is $\varepsilon = \int_{l_o}^{l} dl/l = \ln (l/l_o)$. In this equation, l is the instantaneous length, while l_o is the original length. In terms of the normal strain, the natural strain becomes $\bar{\varepsilon} = \ln (1 + \varepsilon_o)$. Since it is assumed that the volume remains constant, $l/l_o = A_o/A$, and so the natural stress becomes $\bar{S} = P/A = (P/A_o)(1 + \varepsilon_o)$. A_o is the original cross-sectional area. If the natural stress is plotted against strain on log-log paper, the graph is very nearly a straight line. The plastic-range relation is thus approximated by $\bar{S} = K\bar{\varepsilon}^n$, where the proportionality factor K and the **strain-hardening coefficient** n are determined from best fits to experimental data. Values of K and n

Table 5.2.21 Constants *K* and *n* for Sheet Materials

Material	Treatment	K, lb/in^2	n
0.05%C rimmed steel	Annealed	77,100	0.261
0.05%C killed steel	Annealed and tempered	73,100	0.234
Decarburized 0.05%C steel	Annealed in wet H_2	75,500	0.284
0.05/0.07% phos. low C	Annealed	93,330	0.156
SAE 4130	Annealed	169,400	0.118
SAE 4130	Normalized and tempered	154,500	0.156
Type 430 stainless	Annealed	143,000	0.229
Alcoa 24-S	Annealed	55,900	0.211
Reynolds R-301	Annealed	48,450	0.211

determined by Low and Garofalo (*Proc. Soc. Exp. Stress Anal.,* vol. IV, no. 2,1947) are given in Table 5.2.21.

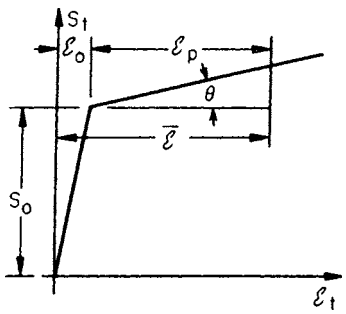

Fig. 5.2.73

The geometry of Fig. 5.2.73 can be used to arrive at a second approximate relation

$$\bar{S} = S_o + (\varepsilon_p - \varepsilon_o)\tan\theta = S_o\left(1 - \frac{H}{E}\right) + \varepsilon_p H$$

where $H = \tan\theta$ is a kind of **plastic modulus.**

The **deformation theory of plastic flow** for the general case of combined stress is developed using the above concepts. Certain additional assumptions involved include: principal plastic-strain directions are the same as principal stress directions; the elastic strain is negligible compared to plastic strain; and the ratios of the three principal shearing strains—$(\bar{\varepsilon}_1 - \bar{\varepsilon}_2)$, $(\bar{\varepsilon}_2 - \bar{\varepsilon}_3)$, $(\bar{\varepsilon}_3 - \bar{\varepsilon}_1)$—to the principal shearing stresses—$(\bar{S}_1 - \bar{S}_2)/2$, $(\bar{S}_2 - \bar{S}_3)/2$, $(\bar{S}_3 - \bar{S}_1)/2$—are equal. The relations between the principal strains and stresses in terms of the simple tension quantities become

$$\bar{\varepsilon}_1 = \bar{\varepsilon}/\bar{S}[\bar{S}_1 - (\bar{S}_2 + \bar{S}_3)/2]$$
$$\bar{\varepsilon}_2 = \bar{\varepsilon}/\bar{S}[\bar{S}_2 - (\bar{S}_3 + \bar{S}_1)/2]$$
$$\bar{\varepsilon}_3 = \bar{\varepsilon}/\bar{S}[\bar{S}_3 - (\bar{S}_1 + \bar{S}_2)/2]$$

If these equations are added, the plastic-flow theory is expressed:

$$\frac{\bar{S}}{\bar{\varepsilon}} = \sqrt{\frac{[(\bar{S}_1 - \bar{S}_2)^2 + (\bar{S}_2 - \bar{S}_3)^2 + (\bar{S}_3 - \bar{S}_1)^2]/2}{2(\bar{\varepsilon}_1^2 + \bar{\varepsilon}_2^2 + \bar{\varepsilon}_3^2)/3}}$$

In the above equation

$$\sqrt{[(\bar{S}_1 - \bar{S}_2)^2 + (\bar{S}_2 - \bar{S}_3)^2 + (\bar{S}_3 - \bar{S}_1)^2]/2} = \bar{S}_e$$

and

$$\sqrt{2(\bar{\varepsilon}_1^2 + \bar{\varepsilon}_2^2 + \bar{\varepsilon}_3^2)/3} = \varepsilon_e$$

are the effective, or significant, stress and strain, respectively,

EXAMPLE. An annealed, stainless-steel type 430 tank has a 41-in inside diameter and has a wall 0.375 in thick. The ultimate strength of the stainless steel is 85,000 lb/in^2. Compute the maximum strain as well as the pressure at fracture.

The tank constitutes a biaxial stress field where $S_1 = pd/(2t)$, $S_2 = pd/(4t)$, and $S_3 = 0$. Taking the power stress-strain relation

$$\bar{S}_e = K\bar{\varepsilon}_e^n \quad \text{or} \quad \bar{\varepsilon}/\bar{S} = \bar{S}_e^{(1-n)/n}/K^{1/n}$$

thus

$$\bar{\varepsilon}_1 = \frac{\bar{S}_e^{(1-n)/n}}{K^{1/n}}\left(\frac{3}{4}\bar{S}_1\right)\bar{\varepsilon} = 0$$

and

$$\bar{\varepsilon}_3 = \frac{\bar{S}_e^{(1-n)/n}}{K^{1/n}}\left(-\frac{3}{4}\bar{S}_t\right) = -\bar{\varepsilon}_1$$

The maximum-shear theory, which is applicable to a ductile material under combined stress, is acceptable here. Thus rupture will occur at

$\bar{S}_1 - \bar{S}_3 = \bar{S}_u$, and

$$\bar{S}_e = \sqrt{\frac{1}{2}\left[\left(\frac{\bar{S}_1}{2}\right)^2 + \left(\frac{\bar{S}_1}{2}\right)^2 + \bar{S}_1^2\right]} = \sqrt{\frac{3}{4}\bar{S}_1^2} = \left(\frac{3}{4}\right)^{1/2}\bar{S}_u$$

$$\bar{\varepsilon}_1 = \frac{[(3/4)]^{1/2}\bar{S}_u]^{(1-n)/n}}{K^{1/n}}\left(\frac{3}{4}\bar{S}_u\right) = \left(\frac{3}{4}\right)^{1+0.229/0.458}\left(\frac{85{,}000}{143{,}000}\right)^{1/0.225}$$
$$= 0.0475 \text{ in/in } (0.0475 \text{ cm/cm})$$

since

$$\bar{S}_u = S_1 = \frac{pd}{2t}, \text{ then } p = \frac{2t\bar{S}_u}{d}$$

or

$$p = \frac{2 \times 0.375 \times 85{,}000}{41} = 1{,}550 \text{ lb/in}^2\,(109 \text{ kgf/cm}^2)$$

ROTATING DISKS

Rotating circular disks may be of various profiles, of constant or variable thickness, with or without centrally and noncentrally located holes, and with radial, tangential, and shearing stresses.

Solution starts with the differential equations of equilibrium and compatibility and the subsequent application of appropriate boundary conditions for the derivation of working-stress equations.

If the disk thickness is small compared with the diameter, the variation of stress with thickness can be assumed to be negligible, and symmetry eliminates the shearing stress. In the rotating case, the disk weight is neglected, but its inertia force becomes the body-force term in the equilibrium equations.

Thus solved, the stress components in a solid disk become

$$\sigma_r = \frac{3+\mu}{8}\rho\omega^2(R^2 - r^2)$$

$$\sigma_\theta = \frac{3+\mu}{8}\rho\omega^2 R^2 - \frac{1+3\mu}{8}\rho\omega^2 r^2$$

where μ = Poisson's ratio; ρ = mass density, lb · s^2/in^4; ω = angular speed, rad/s; R = outside disk radius; and r = radius to point in question.

The largest stresses occur at the center of the solid disk and are

$$\sigma_r = \sigma_\theta = \frac{3 + \mu}{8}\rho\omega^2 R^2$$

A disk with a central hole of radius r_h (no external forces) is subjected to the following stresses:

$$\sigma_r = \frac{3 + \mu}{8}\rho\omega^2\left(R^2 + r_h^2 - \frac{R^2 r_h^2}{r^2} - r^2\right)$$

$$\sigma_\theta = \frac{3 + \mu}{8}\rho\omega^2\left(R^2 + r_h^2 + \frac{R^2 r_h^2}{r^2} - \frac{1 + 3\mu}{3 + \mu}r^2\right)$$

The maximum radial stress $\sigma_r|_M$ occurs at $r = \sqrt{Rr_h}$, and

$$\sigma_r|_M = \frac{3 + \mu}{8}\rho\omega^2(R - r_h)^2$$

The largest tangential stress $\sigma_\theta|_M$ exists at the inner boundary, and

$$\sigma_\theta|_M = \frac{3 + \mu}{4}\rho\omega^2\left(R^2 + \frac{1 - \mu}{3 + \mu}r_h^2\right)$$

As the hole radius r_h approaches zero, the tangential stress assumes a value twice that at the center of a rotating solid disk, given above.

5.3 PIPELINE FLEXURE STRESSES

by Harold V. Hawkins

EDITOR'S NOTE: The almost universal availability and utilization of personal computers in engineering practice has led to the development of many competing and complementary forms of piping stress analysis software. Their use is widespread, and individual packaged software allows analysis and design to take into account static and dynamic conditions, restraint conditions, aboveground and buried configurations, etc. The reader is referred to the technical literature for the most suitable and current software available for use in solving the immediate problems at hand.

The brief discussion in this section addresses the fundamental concepts entailed and sets forth the solution of simple systems as an exercise in application of the principles.

For details of pipe and pipe fittings see Sec. 8.7.

Nomenclature (see Figs. 5.3.1 and 5.3.2)

M_0 = end moment at origin, in · lb (N · m)
M = max moment, in · lb (N · m)
F_x = end reaction at origin in x direction, lb (N)
F_y = end reaction at origin in y direction, lb (N)
S_l = $(Mr/I)\alpha$ = max unit longitudinal flexure stress, lb/in^2 (N/m^2)
S_t = $(Mr/I)\beta$ = max unit transverse flexure stress, lb/in^2 (N/m^2)
S_s = $(Mr/I)\gamma$ = max unit shearing stress, lb/in^2 (N/m^2)
Δx = relative deflection of ends of pipe parallel to x direction caused by either temperature change or support movement, or both, in (m)
Δy = same as Δx but parallel to y direction, in. Note that Δx and Δy are positive if under the change in temperature the end opposite the origin tends to move in a positive x or y direction, respectively.
t = wall thickness of pipe, in (m)
r = mean radius of pipe cross section, in (m)
λ = constant = tR/r^2
I = moment of inertia of pipe cross section about pipe centerline, in^4 (m^4)
E = modulus of elasticity of pipe at *actual working* temperature, lb/in^2 (N/m^2)
K = flexibility index of pipe. $K = 1$ for all straight pipe sections, $K = (10 + 12\lambda^2)/(1 + 12\lambda^2)$ for all curved pipe sections where $\lambda > 0.335$ (see Fig. 5.3.3)
a, β, γ = ratios of actual max longitudinal flexure, transverse flexure, and shearing stresses to Mr/I for curved sections of pipe (see Fig. 5.3.3)

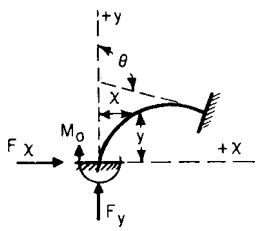

Fig. 5.3.1

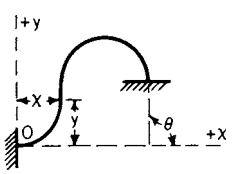

Fig. 5.3.2

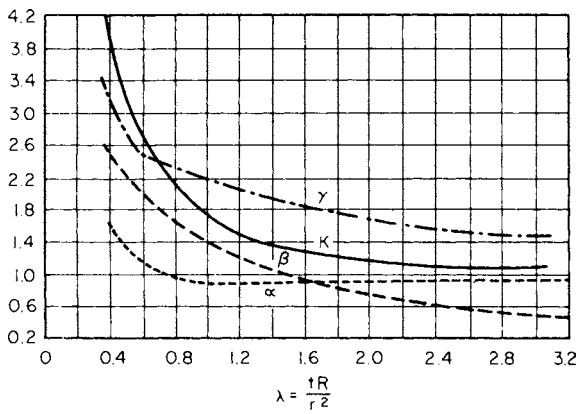

Fig. 5.3.3 Flexure constants of initially curved pipes.

A, B, C, F, G, H = constants given by Table 5.3.2
θ = angle of intersection between tangents to direction of pipe at reactions
$\Delta\theta$ = change in θ caused by movements of supports, or by temperature change, or both, rad
ds = an infinitesimal element of length of pipe
s = length of a particular curved section of pipe, in (m)
R = radius of curvature of pipe centerline, in (m)

General Discussion

Under the effect of changes in temperature of the pipeline, or of movement of support reactions (either translation or rotation), or both, the determination of stress distribution in a pipe becomes a statically indeterminate problem. In general the problem may be solved by a slight modification of the standard arch theory: $\Delta x = -K\int My\, ds/(EI)$, $\Delta y = K\int Mx\, ds/(EI)$, and $\Delta\theta = K\int M\, ds/(EI)$ where the constant K is introduced to correct for the increased flexibility of a curved pipe, and where the integration is over the entire length of pipe between supports. In Table 5.3.1 are given equations derived by this method for moment and thrust at one reaction point for pipes in one plane that are fully fixed, hinged at both ends, hinged at one end and fixed at the other, or partly fixed. If the reactions at one end of the pipe are known, the moment distribution in the entire pipe then can be obtained by simple statics.

Since an initially curved pipe is more flexible than indicated by its moment of inertia, the constant K is introduced. Its value may be taken from Fig. 5.3.3, or computed from the equation given below. $K = 1$ for all straight pipe sections, since they act according to the simple flexure theory.

In Fig. 5.3.3 are given the flexure constants K, α, β, and γ for initially curved pipes as functions of the quantity $\lambda = tR/r^2$. The flexure constants are derived from the equations.

$$K = (10 + 12\lambda^2)/(1 + 12\lambda^2) \qquad \text{when } \lambda > 0.335$$

$$\alpha = \tfrac{2}{3}K\sqrt{(5 + 6\lambda^2)/18} \qquad \lambda \le 1.472$$

$$\alpha = K(6\lambda^2 - 1)/(6\lambda^2 + 5) \qquad \lambda > 1.472$$

$$\beta = 18\lambda/(1 + 12\lambda^2)$$

$$\gamma = [8\lambda - 36\lambda^3 + (32\lambda^2 + 20/3) \times \sqrt{(4/3)\lambda^2 + 5/18}] \div (1 + 12\lambda^2) \qquad \text{when } \lambda < 0.58$$

$$= (12\lambda^2 + 18\lambda - 2)/(1 + 12\lambda^2) \qquad \text{when } \lambda > 0.58$$

Table 5.3.1 General Equations for Pipelines in One Plane (See Figs. 5.3.1 and 5.3.2)

Type of supports	Unsymmetric	Symmetric about y-axis
Both ends fully fixed	$M_0 = \dfrac{EI\,\Delta x(CF - AB) + EI\,\Delta y(BF - AG)}{2ABF + CGH - B^2H - A^2G - CF^2}$ $F_x = \dfrac{EI\,\Delta x(CH - A^2) + EI\,\Delta y(BH - AF)}{2ABF + CGH - B^2H - A^2G - CF^2}$ $F_y = \dfrac{EI\,\Delta x(BH - AF) + EI\,\Delta y(GH - F^2)}{2ABF + CGH - B^2H - A^2G - CF^2}$ $\Delta\theta = 0$	$M_0 = \dfrac{EI\,\Delta x\,F}{GH - F^2}$ $F_x = \dfrac{EI\,\Delta x\,H}{GH - F^2}$ $F_y = 0$ $\Delta\theta = 0$
Both ends hinged	$M_0 = 0$ $F_x = \dfrac{EI\,\Delta x\,C + EI\,\Delta y\,B}{CG - B^2}$ $F_y = \dfrac{EI\,\Delta x\,B + EI\,\Delta y\,G}{CG - B^2}$ $\Delta\theta = \dfrac{\Delta x(AB - CF) + \Delta y(AG - BF)}{CG - B^2}$	$M_0 = 0$ $F_x = \dfrac{EI\,\Delta x}{G}$ $F_y = 0$ $\Delta\theta = \dfrac{-\Delta x\,F}{G}$
Origin end only hinged, other end fully fixed	$M_0 = 0$ $F_x = \dfrac{EI\,\Delta x\,C + EI\,\Delta y\,B}{CG - B^2}$ $F_y = \dfrac{EI\,\Delta x\,B + EI\,\Delta y\,G}{CG + B^2}$ $\Delta\theta = \dfrac{\theta x(AB - CF) + \Delta y(AG - BF)}{CG - B^2}$	
In general for any specific rotation $\Delta\theta$ and movement Δx and Δy . . .	$M_0 = \dfrac{EI\,\Delta x(CF - AB) + EI\,\Delta y(BF - AG) + EI\,\Delta\theta(CG - B^2)}{2ABF + CGH - A^3G - CF^2 - B^2H}$ $F_x = \dfrac{EI\,\Delta x(CH - A^2) + EI\,\Delta y(BH - AF) + EI\,\Delta\theta(CF - AB)}{2ABF + CGH - A^2G - CF^2 - B^2H}$ $F_y = \dfrac{EI\,\Delta x(BH - AF) + EI\,\Delta y(GH - F^2) + EI\,\Delta\theta(BF - AG)}{2ABF + CGH - A^2G - CF^2 - B^2H}$	

The increased flexibility of the curved pipe is brought about by the tendency of its cross section to flatten. This flattening causes a transverse flexure stress whose maximum is S_r. Because the maximum longitudinal and maximum transverse stresses do not occur at the same point in the pipe's cross section, the resulting maximum shear is not one-half the difference of S_l and S_t; it is S_s. In the straight sections of the pipe, $\alpha = 1$, the transverse stress disappears, and $\lambda = \frac{1}{2}$. This discussion of S_s does not include the uniform transverse or longitudinal tension stresses induced by the internal pressure in the pipe; their effects should be added if appreciable.

Table 5.3.2 gives values of the constants A, B, C, F, G, and H for use in equations listed in Table 5.3.1. The values may be used (1) for the solution of any pipeline or (2) for the derivation of equations for standard shapes composed of straight sections and arcs of circles as of Fig. 5.3.5. Equations for shapes not given may be obtained by algebraic addition of those given. All measurements are from the left-hand end of the pipeline. Reactions and stresses are greatly influenced by end conditions. Formulas are given to cover the extreme conditions. The following suggestions and comments should be considered when laying out a pipeline:

Avoid expansion bends, and design the entire pipeline to take care of its own expansion.

The movement of the equipment to which the ends of the pipeline are attached must be included in the Δx and Δy of the equations.

Maximum flexibility is obtained by placing **supports** and **anchors** so that they will not interfere with the natural movement of the pipe.

That shape is most efficient in which the **maximum length of pipe is working** at the maximum safe stress.

Excessive **bending moment at joints** is more likely to cause trouble than excessive stresses in pipe walls. Hence, keep pipe joints away from points of high moment.

Reactions and stresses are greatly influenced by **flattening of the cross section** of the curved portions of the pipeline.

It is recommended that **cold springing** allowances be discounted in stress calculations.

Application to Two- and Three-Plane Pipelines Pipelines in more than one plane may be solved by the successive application of the preceding data, dividing the pipeline into two or more one-plane lines.

EXAMPLE 1. The unsymmetric pipeline of Fig. 5.3.4 has fully fixed ends. From Table 5.3.2 use $K = 1$ for all sections, since only straight segments are involved.

Upon introduction of $a = 120$ in (3.05 m), $b = 60$ in (1.52 m), and $c = 180$ in (4.57 m), into the preceding relations (Table 5.3.3) for A, B, C, F, G, H, the equations for the reactions at 0 from Table 5.3.1 become

$$M_0 = EI\Delta x(-7.1608 \times 10^{-5}) + EI\Delta y(-8.3681 \times 10^{-5})$$

$$F_x = EI\Delta x(+1.0993 \times 10^{-5}) + EI\Delta y(+3.1488 \times 10^{-6})$$

$$F_y = EI\Delta x(+3.1488 \times 10^{-6}) + EI\Delta y(+1.33717 \times 10^{-6})$$

Also it follows that

$$M_1 = M_0 + F_y a = EI\Delta x(+3.0625 \times 10^{-4}) + EI\Delta y(+7.6799 \times 10^{-5})$$

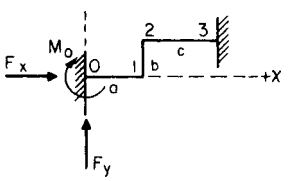

Fig. 5.3.4

$$M_2 = M_1 - F_x b = EI\Delta x(-3.5333 \times 10^{-4}) + EI\Delta y(-1.1215 \times 10^{-4})$$

$$M_3 = M_2 + F_y c = EI\Delta x(+2.1345 \times 10^{-4}) + EI\Delta y(+1.2854 \times 10^{-4})$$

Thus the maximum moment M occurs at 3.

The total maximum longitudinal fiber stress ($a = 1$ for straight pipe)

$$S_l = \frac{F_x}{2\pi rt} \pm \frac{M_3 r}{I}$$

There is no transverse flexure stress since all sections are straight. The maximum shearing stress is either (1) one-half of the maximum longitudinal fiber stress as given above, (2) one-half of the hoop-tension stress caused by an internal radial pressure that might exist in the pipe, or (3) one-half the difference of the maximum longitudinal fiber stress and hoop-tension stress, whichever of these three possibilities is numerically greatest.

EXAMPLE 2. The equations of Table 5.3.1 may be employed to develop the solution of generalized types of pipe configurations for which Fig. 5.3.5 is a typical example. If only temperature changes are considered, the reactions for the right-angle pipeline (Fig. 5.3.5) may be determined from the following equations:

$$M_0 = C_1 EI\,\Delta x/R^2$$

$$F_x = C_2 EI\,\Delta x/R^3$$

$$F_y = C_3 EI\,\Delta x/R^3$$

In these equations, Δx is the x component of the deflection between reaction points caused by temperature change only. The values of C_1, C_2, and C_3 are given in Fig. 5.3.6 for $K = 1$ and $K = 2$. For other values of K, interpolation may be employed.

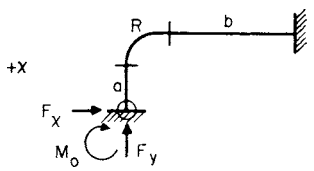

Fig. 5.3.5 Right angle pipeline.

EXAMPLE 3. With $a/R = 20$ and $b/R = 3$, the value of C_1 is 0.185 for $K = 1$ and 0.165 for $K = 2$. If $K = 1.75$, the interpolated value of C_1 is 0.175.

Elimination of Flexure Stresses Pipeline flexure stresses that normally would result from movement of supports or from the tendency of the pipes to expand under temperature change often may be avoided entirely through the use of expansion joints (Sec. 8.7). Their use may simplify both the design of the pipeline and the support structure. When using expansion joints, the following suggestions should be considered: (1) select the expansion joint carefully for maximum temperature range (and deflection) expected so as to prevent damage to expansion fitting; (2) provide guides to limit movement at the expansion joint to direction permitted by joint; (3) provide adequate anchors at one end of each straight section or along its midlength, forcing movement to occur at the expansion joint yet providing adequate support for the pipeline; (4) mount expansion joints adjacent to an anchor point to prevent sagging of the pipeline under its own weight and do not depend upon the expansion joint for stiffness—it is intended to be flexible; (5) give consideration to effects of corrosion, since the corrugated character of expansion joints makes cleaning difficult.

Table 5.3.2 Values of *A*, *B C*, *F*, *G*, and *H* for Various Piping Elements

	$A = K\int x\,ds$	$B = K\int xy\,ds$	$C = K\int x^2\,ds$	$F = K\int y\,ds$	$G = K\int y^2\,ds$	$H = K\int ds$

Nondestructive tests are those tests that determine the usefulness, serviceability, or quality of a part or material without limiting its usefulness. Nondestructive tests are used in machinery maintenance to avoid costly unscheduled loss of service due to fatigue or wear; they are used in manufacturing to ensure product quality and minimize costs. Consideration of test requirements early in the design of a product may facilitate testing and minimize testing cost. Nearly every form of energy is used in nondestructive tests, including all wavelengths of the electromagnetic spectrum as well as vibrational mechanical energy. Physical properties, composition, and structure are determined; flaws are detected; and thickness is measured. These tests are here divided into the following basic methods: **magnetic particle, penetrant, radiographic, ultrasonic, eddy current, acoustic emission, microwave, and infrared.** Numerous techniques are utilized in the application of each test method. Table 5.4.1 gives a summary of many nondestructive test methods.

MAGNETIC PARTICLE METHODS

Magnetic particle testing is a nondestructive method for detecting discontinuities at or near the surface in **ferromagnetic materials.** After the test object is properly magnetized, finely divided magnetic particles are applied to its surface. When the object is properly oriented to the induced magnetic field, a discontinuity creates a leakage flux which attracts and holds the particles, forming a visible indication. Magnetic-field direction and character are dependent upon how the magnetizing force is applied and upon the type of current used. For best sensitivity, the **magnetizing current** must flow in a direction parallel to the principal direction of the expected defect. Circular fields, produced by passing current through the object, are almost completely contained within the test object. Longitudinal fields, produced by coils or yokes, create external poles and a general-leakage field. Alternating, direct, or half-wave direct current may be used for the location of surface defects. Half-wave direct current is most effective for locating subsurface defects. Magnetic particles may be applied dry or as a wet suspension in a liquid such as kerosene or water. Colored **dry powders** are advantageous when testing for subsurface defects and when testing objects that have rough surfaces, such as castings, forgings, and weldments. **Wet particles** are preferred for detection of very fine cracks, such as fatigue, stress corrosion, or grinding cracks. Fluorescent wet particles are used to inspect objects with the aid of ultraviolet light. Fluorescent inspection is widely used because of its greater sensitivity. Application of particles while magnetizing current is on (continuous method) produces stronger indications than those obtained if the particles are applied after the current is shut off (residual method). Interpretation of subsurface-defect indications requires experience. Demagnetization of the test object after inspection is advisable.

Magnetic flux leakage is a variation whereby leakage flux due to flaws is detected electronically via a Hall-effect sensor. Computerized signal interpretation and data imaging techniques are employed.

Electrified particle testing indicates minute cracks in nonconducting materials. Particles of calcium carbonate are positively charged as they are blown through a spray gun at the test object. If the object is metal-backed, such as porcelain enamel, no preparation other than cleaning is necessary. When it is not metal-backed, the object must be dipped in an aqueous penetrant solution and dried. The penetrant remaining in cracks provides a mobile electron supply for the test. A readily visible powder indication forms at a crack owing to the attraction of the positively charged particles.

PENETRANT METHODS

Liquid penetrant testing is used to locate flaws open to the surface of **nonporous materials.** The test object must be thoroughly cleaned before testing. Penetrating liquid is applied to the surface of a test object by a brush, spray, flow, or dip method. A time allowance (1 to 30 min) is required for liquid penetration of surface flaws. Excess penetrant is then carefully removed from the surface, and an absorptive coating, known as developer, is applied to the object to draw penetrant out of flaws, thus showing their location, shape, and approximate size. The developer is typically a fine powder, such as talc usually in suspension in a liquid. Penetrating-liquid types are (1) for test in visible light, and (2) for test under ultraviolet light (3,650 Å). Sensitivity of penetrant testing is greatest when a fluorescent penetrant is used and the object is

Table 5.4.1 Nondestructive Test Methods*

Method	Measures or detects	Applications	Advantages	Limitations
Acoustic emission	Crack initiation and growth rate Internal cracking in welds during cooling Boiling or cavitation Friction or wear Plastic deformation Phase transformations	Pressure vessels Stressed structures Turbine or gearboxes Fracture mechanics research Weldments Sonic-signature analysis	Remote and continuous surveillance Permanent record Dynamic (rather than static) detection of cracks Portable Triangulation techniques to locate flaws	Transducers must be placed on part surface Highly ductile materials yield low-amplitude emissions Part must be stressed or operating Interfering noise needs to be filtered out
Acoustic-impact (tapping)	Debonded areas or delaminations in metal or nonmetal composites or laminates Cracks under bolt or fastener heads Cracks in turbine wheels or turbine blades Loose rivets or fastener heads Crushed core	Brazed or adhesive-bonded structures Bolted or riveted assemblies Turbine blades Turbine wheels Composite structures Honeycomb assemblies	Portable Easy to operate May be automated Permanent record or positive meter readout No couplant required	Part geometry and mass influences test results Impactor and probe must be repositioned to fit geometry of part Reference standards required Pulser impact rate is critical for repeatability
D-Sight (Diffracto)	Enhances visual inspection for surface abnormalities such as dents protrusions, or waviness Crushed core Lap joint corrosion Cold-worked holes Cracks	Detect impact damage to composites or honeycomb corrosion in aircraft lap joints Automotive bodies for waviness	Portable Fast, flexible Noncontact Easy to use Documentable	Part surface must reflect light or be wetted with a fluid
Eddy current	Surface and subsurface cracks and seams Alloy content Heat-treatment variations Wall thickness, coating thickness Crack depth Conductivity Permeability	Tubing Wire Ball bearings "Spot checks" on all types of surfaces Proximity gage Metal detector Metal sorting Measure conductivity in % IACS	No special operator skills required High speed, low cost Automation possible for symmetric parts Permanent-record capability for symmetric parts No couplant or probe contact required	Conductive materials Shallow depth of penetration (thin walls only) Masked or false indications caused by sensitivity to variations such as part geometry Reference standards required Permeability variations
Magneto-optic eddy-current imager	Cracks Corrosion thinning in aluminum	Aluminum aircraft Structure	Real-time imaging Approximately 4-in area coverage	Frequency range of 1.6 to 100 kHz Surface contour Temperature range of 32 to 90°F Directional sensitivity to cracks
Eddy-sonic	Debonded areas in metal-core or metal-faced honeycomb structures Delaminations in metal laminates or composites Crushed core	Metal-core honeycomb Metal-faced honeycomb Conductive laminates such as boron or graphite-fiber composites Bonded-metal panels	Portable Simple to operate No couplant required Locates far-side debonded areas Access to only one surface required May be automated	Specimen or part must contain conductive materials to establish eddy-current field Reference standards required Part geometry
Electric current	Cracks Crack depth Resistivity Wall thickness Corrosion-induced wall thinning	Metallic materials Electrically conductive materials Train rails Nuclear fuel elements Bars, plates other shapes	Access to only one surface required Battery or dc source Portable	Edge effect Surface contamination Good surface contact required Difficult to automate Electrode spacing Reference standards required
Electrified particle	Surface flaws in nonconducting material Through-to-metal pinholes on metal-backed material Tension, compression, cyclic cracks Brittle-coating stress cracks	Glass Porcelain enamel Nonhomogeneous materials such as plastic or asphalt coatings Glass-to-metal seals	Portable Useful on materials not practical for penetrant inspection	Poor resolution on thin coatings False indications from moisture streaks or lint Atmospheric conditions High-voltage discharge

Table 5.4.1 Nondestructive Test Methods* (*Continued*)

Method	Measures or detects	Applications	Advantages	Limitations
Filtered particle	Cracks Porosity Differential absorption	Porous materials such as clay, carbon, powdered metals, concrete Grinding wheels High-tension insulators Sanitary ware	Colored or fluorescent particles Leaves no residue after baking part over 400°F Quickly and easily applied Portable	Size and shape of particles must be selected before use Penetrating power of suspension medium is critical Particle concentration must be controlled Skin irritation
Infrared (radiometry) (thermography)	Hot spots Lack of bond Heat transfer Isotherms Temperature ranges	Brazed joints Adhesive-bonded joints Metallic platings or coatings; debonded areas or thickness Electrical assemblies Temperature monitoring	Sensitive to 0.1°F temperature variation Permanent record or thermal picture Quantitative Remote sensing; need not contact part Portable	Emissivity Liquid-nitrogen-cooled detector Critical time-temperature relationship Poor resolution for thick specimens Reference standards required
Leak testing	Leaks: Helium Ammonia Smoke Water Air bubbles Radioactive gas Halogens	Joints: Welded Brazed Adhesive-bonded Sealed assemblies Pressure or vacuum chambers Fuel or gas tanks	High sensitivity to extremely small, light separations not detectable by other NDT methods Sensitivity related to method selected	Accessibility to both surfaces of part required Smeared metal or contaminants may prevent detection Cost related to sensitivity
Magnetic particle	Surface and slightly subsurface flaws; cracks, seams, porosity, inclusions Permeability variations Extremely sensitive for locating small tight cracks	Ferromagnetic materials; bar, plate, forgings, weldments, extrusions, etc.	Advantage over penetrant is that it indicates subsurface flaws, particularly inclusions Relatively fast and low-cost May be portable	Alignment of magnetic field is critical Demagnetization of parts required after tests Parts must be cleaned before and after inspection Masking by surface coatings
Magnetic field (also magnetic flux leakage)	Cracks Wall thickness Hardness Coercive force Magnetic anisotropy Magnetic field Nonmagnetic coating thickness on steel	Ferromagnetic materials Ship degaussing Liquid-level control Treasure hunting Wall thickness of nonmetallic materials Material sorting	Measurement of magnetic material properties May be automated Easily detects magnetic objects in nonmagnetic material Portable	Permeability Reference standards required Edge effect Probe lift-off
Microwave (300 MHz–300 GHz)	Cracks, holes, debonded areas, etc., in nonmetallic parts Changes in composition, degree of cure, moisture content Thickness measurement Dielectric constant Loss tangent	Reinforced plastics Chemical products Ceramics Resins Rubber Wood Liquids Polyurethane foam Radomes	Between radio waves and infrared in electromagnetic spectrum Portable Contact with part surface not normally required Can be automated	Will not penetrate metals Reference standards required Horn-to-part spacing critical Part geometry Wave interference Vibration
Liquid penetrants (dye or fluorescent)	Flaws open to surface of parts; cracks, porosity, seams, laps, etc. Through-wall leaks	All parts with nonabsorbing surfaces (forgings, weldments, castings, etc.). Note: Bleed-out from porous surfaces can mask indications of flaws	Low cost Portable Indications may be further examined visually Results easily interpreted	Surface films such as coatings, scale, and smeared metal may prevent detection of flaws Parts must be cleaned before and after inspection Flaws must be open to surface
Fluoroscopy (cinefluorography) (kinefluorography)	Level of fill in containers Foreign objects Internal components Density variations Voids, thickness Spacing or position	Flow of liquids Presence of cavitation Operation of valves and switches Burning in small solid-propellant rocket motors	High-brightness images Real-time viewing Image magnification Permanent record Moving subject can be observed	Costly equipment Geometric unsharpness Thick specimens Speed of event to be studied Viewing area Radiation hazard

Table 5.4.1 Nondestructive Test Methods* (*Continued*)

Method	Measures or detects	Applications	Advantages	Limitations
Neutron radiology (thermal neutrons from reactor, accelerator, or Californium 252)	Hydrogen contamination of titanium or zirconium alloys Defective or improperly loaded pyrotechnic devices Improper assembly of metal, nonmetal parts Corrosion products	Pyrotechnic devices Metallic, nonmetallic assemblies Biological specimens Nuclear reactor fuel elements and control rods Adhesive-bonded structures	High neutron absorption by hydrogen, boron, lithium, cadmium, uranium, plutonium Low neutron absorption by most metals Complement to X-ray or gamma-ray radiography	Very costly equipment Nuclear reactor or accelerator required Trained physicists required Radiation hazard Nonportable Indium or gadolinium screens required
Gamma radiology (cobalt 60, iridium 192)	Internal flaws and variations, porosity, inclusions, cracks, lack of fusion, geometry variations, corrosion thinning Density variations Thickness, gap, and position	Usually where X-ray machines are not suitable because source cannot be placed in part with small openings and/or power source not available Panoramic imaging	Low initial cost Permanent records; film Small sources can be placed in parts with small openings Portable Low contrast	One energy level per source Source decay Radiation hazard Trained operators needed Lower image resolution Cost related to source size
X-ray radiology	Internal flaws and variations; porosity, inclusions, cracks, lack of fusion, geometry variations, corrosion Density variations Thickness, gap, and position Misassembly Misalignment	Castings Electrical assemblies Weldments Small, thin, complex wrought products Nonmetallics Solid-propellant rocket motors Composites Container contents	Permanent records; film Adjustable energy levels (5 kV–25 meV) High sensitivity to density changes No couplant required Geometry variations do not affect direction of X-ray beam	High initial costs Orientation of linear flaws in part may not be favorable Radiation hazard Depth of flaw not indicated Sensitivity decreases with increase in scattered radiation
Radiometry X-ray, gamma ray, beta ray (transmission or backscatter)	Wall thickness Plating thickness Variations in density or composition Fill level in cans or containers Inclusions or voids	Sheet, plate, strip, tubing Nuclear reactor fuel rods Cans or containers Plated parts Composites	Fully automatic Fast Extremely accurate In-line process control Portable	Radiation hazard Beta ray useful for ultrathin coatings only Source decay Reference standards required
Reverse-geometry digital X-ray	Cracks Corrosion Water in honeycomb Carbon epoxy honeycomb Foreign objects	Aircraft structure	High-resolution 10^6 pixel image with high contrast	Access to both sides of object Radiation hazard
X-ray computed tomography (CT)	Small density changes Cracks Voids Foreign objects	Solid-propellant rocket motors Rocket nozzles Jet-engine parts Turbine blades	Measures X-ray opacity of object along many paths	Very expensive Trained operator Radiation hazard
Shearography electronic	Lack of bond Delaminations Plastic deformation Strain Crushed core Impact damage Corrosion in Al honeycomb	Composite-metal honeycomb Bonded structures Composite structures	Large area coverage Rapid setup and operation Noncontacting Video image easy to store	Requires vacuum thermal, ultrasonic, or microwave stressing of structure to cause surface strain
Thermal (thermochromic paint, liquid crystals)	Lack of bond Hot spots Heat transfer Isotherms Temperature ranges Blockage in coolant passages	Brazed joints Adhesive-bonded joints Metallic platings or coatings Electrical assemblies Temperature monitoring	Very low initial cost Can be readily applied to surfaces which may be difficult to inspect by other methods No special operator skills	Thin-walled surfaces only Critical time-temperature relationship Image retentivity affected by humidity Reference standards required
Sonic (less than 0.1 MHz)	Debonded areas or delaminations in metal or nonmetal composites or laminates Cohesive bond strength under controlled conditions Crushed or fractured core Bond integrity of metal insert fasteners	Metal or nonmetal composite or laminates brazed or adhesive-bonded Plywood Rocket-motor nozzles Honeycomb	Portable Easy to operate Locates far-side debonded areas May be automated Access to only one surface required	Surface geometry influences test results Reference standards required Adhesive or core-thickness variations influence results

Table 5.4.1 Nondestructive Test Methods* (*Continued*)

Method	Measures or detects	Applications	Advantages	Limitations
Ultrasonic (0.1–25 MHz)	Internal flaws and variations; cracks, lack of fusion, porosity, inclusions, delaminations, lack of bond, texturing Thickness or velocity Poisson's ratio, elastic modulus	Metals Welds Brazed joints Adhesive-bonded joints Nonmetallics In-service parts	Most sensitive to cracks Test results known immediately Automating and permanent-record capability Portable High penetration capability	Couplant required Small, thin, or complex parts may be difficult to inspect Reference standards required Trained operators for manual inspection Special probes
Thermoelectric probe	Thermoelectric potential Coating thickness Physical properties Thompson effect *P-N* junctions in semiconductors	Metal sorting Ceramic coating thickness on metals Semiconductors	Portable Simple to operate Access to only one surface required	Hot probe Difficult to automate Reference standards required Surface contaminants Conductive coatings

* From Donald J. Hagemaier, "Metal Progress Databook," Douglas Aircraft Co., McDonnell-Douglas Corp., Long Beach, CA.

observed in a semidarkened location. After testing, the penetrant and developer are removed by washing with water, sometimes aided by an emulsifier, or with a solvent.

In **filtered particle** testing, cracks in **porous objects** (100 mesh or smaller) are indicated by the difference in absorption between a cracked and a flaw-free surface. A liquid containing suspended particles is sprayed on a test object. If a crack exists, particles are filtered out and concentrate at the surface as liquid flows into the additional absorbent area created by the crack. Fluorescent or colored particles are used to locate flaws in unfired dried clay, certain fired ceramics, concrete, some powdered metals, carbon, and partially sintered tungsten and titanium carbides.

RADIOGRAPHIC METHODS

Radiographic test methods employ X-rays, gamma rays, or similar penetrating radiation to reveal flaws, voids, inclusions, thickness, or structure of objects. Electromagnetic energy wavelengths in the range of 0.01 to 10 Å (1 Å = 10^{-8} cm) are used to examine the interior of opaque materials. Penetrating radiation proceeds from its source in straight lines to the test object. Rays are differentially absorbed by the object, depending upon the energy of the radiation and the nature and thickness of the material.

X-rays of a variety of wavelengths result when high-speed electrons in a vacuum tube are suddenly stopped. An X-ray tube contains a heated filament (cathode) and a target (anode); radiation intensity is almost directly proportional to filament current (mA); tube voltage (kV) determines the penetration capability of the rays. As tube voltage increases, shorter wavelengths and more intense X-rays are produced. When the energy of penetrating radiation increases, shorter wavelengths and more intense X-rays are produced. Also, when the energy of penetrating radiation increases, the difference in attenuation between materials decreases. Consequently, more film-image contrast is obtained at lower voltage, and a greater range of thickness can be radiographed at one time at higher voltage.

Gamma rays of a specific wavelength are emitted from the disintegrating nuclei of natural radioactive elements, such as radium, and from a variety of artificial radioactive isotopes produced in nuclear reactors. Cobalt 60 and iridium 192 are commonly used for industrial radiography. The half-life of an isotope is the time required for half of the radioactive material to decay. This time ranges from a few hours to many years.

Radiographs are photographic records produced by the passage of penetrating radiation onto a film. A void or reduced mass appears as a darker image on the film because of the lesser absorption of energy and the resulting additional exposure of the film. The quantity of X-rays absorbed by a material generally increases as the atomic number increases.

A radiograph is a shadow picture, since X-rays and gamma rays follow the laws of light in shadow formation. Four factors determine the best geometric sharpness of a picture: (1) The effective focal-spot size of the radiation source should be as small as possible. (2) The source-to-object distance should be adequate for proper definition of the area of the object farthest from the film. (3) The film should be as close as possible to the object. (4) The area of interest should be in the center of and perpendicular to the X-ray beams and parallel to the X-ray film.

Radiographic films vary in speed, contrast, and grain size. Slow films generally have smaller grain size and produce more contrast. Slow films are used where optimum sharpness and maximum contrast are desired. Fast films are used where objects with large differences in thickness are to be radiographed or where sharpness and contrast can be sacrificed to shorten exposure time. Exposure of a radiographic film comes from direct radiation and scattered radiation. **Direct radiation** is desirable, image-forming radiation; **scattered radiation,** which occurs in the object being X-rayed or in neighboring objects, produces undesirable images on the film and loss of contrast. **Intensifying screens** made of 0.005- or 0.010-in- (0.13-mm or 0.25-mm) thick lead are often used for radiography at voltages above 100 kV. The lead filters out much of the low-energy scatter radiation. Under action of X-rays or gamma rays above 88 kV, a lead screen also emits electrons which, when in intimate contact with the film, produce additional coherent darkening of the film. Exposure time can be materially reduced by use of intensifying screens above and below the film.

Penetrameters are used to indicate the contrast and definition which exist in a radiograph. The type generally used in the United States is a small rectangular plate of the same material as the object being X-rayed. It is uniform in thickness (usually 2 percent of the object thickness) and has holes drilled through it. ASTM specifies hole diameters 1, 2, and 4 times the thickness of the penetrameter. Step, wire, and bead penetrameters are also used. (See ASTM Materials Specification E94.)

Because of the variety of factors that affect the production and measurements of an X-ray image, operating factors are generally selected from reference tables or graphs which have been prepared from test data obtained for a range of operating conditions.

All materials may be inspected by radiographic means, but there are limitations to the configurations of materials. With optimum techniques, wires 0.0001 in (0.003 mm) in diameter can be resolved in small electrical components. At the other extreme, welded steel pressure vessels with 20-in (500-mm) wall thickness can be routinely inspected by use of high-energy accelerators as a source of radiation. **Neutron radiation** penetrates extremely dense materials such as lead more readily than X-rays or gamma rays but is attenuated by lighter-atomic-weight materials such as plastics, usually because of their hydrogen content.

Radiographic standards are published by ASTM, ASME, AWS, and API, primarily for detecting lack of penetration or lack of fusion in welded objects. Cast-metal objects are radiographed to detect

conditions such as shrink, porosity, hot tears, cold shuts, inclusions, coarse structure, and cracks.

The usual method of utilizing penetrating radiation employs film. However, Geiger counters, semiconductors, phosphors (fluoroscopy), photoconductors (xeroradiography), scintillation crystals, and vidicon tubes (image intensifiers) are also used. Computerized digital radiography is an expanding technology.

The **dangers** connected with exposure of the human body to X-rays and gamma rays should be fully understood by any person responsible for the use of radiation equipment. NIST is a prime source of information concerning radiation safety. NRC specifies maximum permissible exposure to be a 1.25 R/¼ year.

ULTRASONIC METHODS

Ultrasonic nondestructive test methods employ high-frequency mechanical vibrational energy to detect and locate structural discontinuities or differences and to measure thickness of a variety of materials. An electric pulse is generated in a test instrument and transmitted to a transducer, which converts the electric pulse into mechanical vibrations. These low-energy-level vibrations are transmitted through a coupling liquid into the test object, where the ultrasonic energy is attenuated, scattered, reflected, or resonated to indicate conditions within material. Reflected, transmitted, or resonant sound energy is reconverted to electrical energy by a transducer and returned to the test instrument, where it is amplified. The received energy is then usually displayed on a cathode-ray tube. The presence, position, and amplitude of echoes indicate conditions of the test-object material.

Materials capable of being tested by ultrasonic energy are those which transmit vibrational energy. Metals are tested in dimensions of up to 30 ft (9.14 m). Noncellular plastics, ceramics, glass, new concrete, organic materials, and rubber can be tested. Each material has a characteristic sound velocity, which is a function of its density and modulus (elastic or shear).

Material characteristics determinable through ultrasonics include structural discontinuities, such as flaws and unbonds, physical constants and metallurgical differences, and thickness (measured from one side). A common application of ultrasonics is the inspection of welds for inclusions, porosity, lack of penetration, and lack of fusion. Other applications include location of unbond in laminated materials, location of fatigue cracks in machinery, and medical applications. Automatic testing is frequently performed in manufacturing applications.

Ultrasonic systems are classified as either **pulse-echo,** in which a single transducer is used, or **through-transmission,** in which separate sending and receiving transducers are used. Pulse-echo systems are more common. In either system, ultrasonic energy must be transmitted into, and received from, the test object through a **coupling medium,** since air will not efficiently transmit ultrasound of these frequencies. Water, oil, grease, and glycerin are commonly used couplants. Two types of testing are used: contact and immersion. In contact testing, the transducer is placed directly on the test object. In immersion testing, the transducer and test object are separated from one another in a tank filled with water or by a column of water or by a liquid-filled wheel. Immersion testing eliminates transducer wear and facilitates scanning of the test object. Scanning systems have paper-printing or computerized video equipment for readout of test information.

Ultrasonic transducers are piezoelectric units which convert electric energy into acoustic energy and convert acoustic energy into electric energy of the same frequency. Quartz, barium titanate, lithium sulfate, lead metaniobate, and lead zirconate titanate are commonly used transducer crystals, which are generally mounted with a damping backing in a housing. Transducers range in size from 1/16 to 5 in (0.15 to 12.7 cm) and are circular or rectangular. Ultrasonic beams can be focused to improve resolution and definition. Transducer characteristics and beam patterns are dependent upon frequency, size, crystal material, and construction.

Test frequencies used range from 40 kHz to 200 MHz. Flaw-detection and thickness-measurement applications use frequencies between 500 kHz and 25 MHz, with 2.25 and 5 MHz being most commonly employed for flaw detection. Low frequencies (40 kHz to 1.0 MHz) are used on materials of low elastic modulus or large grain size. High frequencies (2.25 to 25 MHz) provide better resolution of smaller defects and are used on fine-grain materials and thin sections. Frequencies above 25 MHz are employed for investigation and measurement of physical properties related to acoustic attenuation.

Wave-vibrational modes other than longitudinal are effective in detecting flaws that do not present a reflecting surface to the ultrasonic beam, or other characteristics not detectable by the longitudinal mode. They are useful also when large areas of plates must be examined. Wedges of plastic, water, or other material are inserted between the transducer face and the test object to convert, by refraction, to shear, transverse, surface, or Lamb vibrational modes. As in optics, Snell's law expresses the relationship between incident and refracted beam angles; i.e., the ratio of the sines of the angle from the normal, of the incident and refracted beams in two mediums, is equal to the ratio of the mode acoustic velocities in the two mediums.

Limiting conditions for ultrasonic testing may be the test-object shape, surface roughness, grain size, material structure, flaw orientation, selectivity of discontinuities, and the skill of the operator. Test sensitivity is less for cast metals than for wrought metals because of grain size and surface differences.

Standards for acceptance are published in many government, national society, and company specifications (see references above). Evaluation is made by comparing (visually or by automated electronic means) received signals with signals obtained from reference blocks containing flat bottom holes between 1/64 and 3/64 in (0.40 and 0.325 cm) in diameter, or from parts containing known flaws, drilled holes, or machined notches.

EDDY CURRENT METHODS

Eddy current nondestructive tests are based upon correlation between electromagnetic properties and physical or structural properties of a test object. Eddy currents are induced in metals whenever they are brought into an ac magnetic field. These eddy currents create a secondary magnetic field, which opposes the inducing magnetic field. The presence of discontinuities or material variations alters eddy currents, thus changing the apparent impedance of the inducing coil or of a detection coil. Coil impedance indicates the magnitude and phase relationship of the eddy currents to their inducing magnetic-field current. This relationship is dependent upon the mass, conductivity, permeability, and structure of the metal and upon the frequency, intensity, and distribution of the alternating magnetic field. Conditions such as heat treatment, composition, hardness, phase transformation, case depth, cold working, strength, size, thickness, cracks, seams, and inhomogeneities are indicated by eddy current tests. Correlation data must usually be obtained to determine whether test conditions for desired characteristics of a particular test object can be established. Because of the many factors which cause variation in electromagnetic properties of metals, care must be taken that the instrument response to the condition of interest is not nullified or duplicated by variations due to other conditions.

Alternating-current **frequencies** between 1 and 5,000,000 Hz are used for eddy current testing. Test frequency determines the depth of current penetration into the test object, owing to the ac phenomenon of "skin effect." One "standard depth of penetration" is the depth at which the eddy currents are equal to 37 percent of their value at the surface. In a plane conductor, depth of penetration varies inversely as the square root of the product of conductivity, permeability, and frequency. High-frequency eddy currents are more sensitive to surface flaws or conditions while low-frequency eddy currents are sensitive also to deeper internal flaws or conditions.

Test coils are of three general types: the **circular coil,** which surrounds an object; the **bobbin coil,** which is inserted within an object; and the **probe coil,** which is placed on the surface of an object. Coils are further classified as **absolute,** when testing is conducted without direct comparison with a reference object in another coil; or **differential,** when

comparison is made through use of two coils connected in series opposition. Many variations of these coil types are utilized. Axial length of a circular test coil should not be more than 4 in (10.2 cm), and its shape should correspond closely to the shape of the test object for best results. Coil diameter should be only slightly larger than the test-object diameter for consistent and useful results. Coils may be of the air-core or magnetic-core type.

Instrumentation for the analysis and presentation of electric signals resulting from eddy current testing includes a variety of means, ranging from meters to oscilloscopes to computers. Instrument meter or alarm circuits are adjusted to be sensitive only to signals of a certain electrical phase or amplitude, so that selected conditions are indicated while others are ignored. Automatic and automated testing is one of the principal advantages of the method.

Thickness measurement of metallic and nonmetallic coatings on metals is performed using eddy current principles. Coating thicknesses measured typically range from 0.0001 to 0.100 in (0.00025 to 0.25 cm). For measurement to be possible, coating conductivity must differ from that of the base metal.

MICROWAVE METHODS

Microwave test methods utilize electromagnetic energy to determine characteristics of nonmetallic substances, either solid or liquid. Frequencies used range from 1 to 3,000 GHz. Microwaves generated in a test instrument are transmitted by a waveguide through air to the test object. Analysis of reflected or transmitted energy indicates certain material characteristics, such as moisture content, composition, structure, density, degree of cure, aging, and presence of flaws. Other applications include thickness and displacement measurement in the range of 0.001 in (0.0025 cm) to more than 12 in (30.4 cm). Materials that can be tested include most solid and liquid nonmetals, such as chemicals, minerals, plastics, wood, ceramics, glass, and rubber.

INFRARED METHODS

Infrared nondestructive tests involve the detection of infrared electromagnetic energy emitted by a test object. Infrared radiation is produced naturally by all matter at all temperatures above absolute zero. Materials emit radiation at varying intensities, depending upon their temperature and surface characteristics. A **passive** infrared system detects the natural radiation of an unheated test object, while an **active** system employs a source to heat the test object, which then radiates infrared energy to a detector. Sensitive indication of temperature or temperature distribution through infrared detection is useful in locating irregularities in materials, in processing, or in the functioning of parts. Emission in the infrared range of 0.8 to 15 μm is collected optically, filtered, detected, and amplified by a test instrument which is designed around the characteristics of the detector material. Temperature variations on the order of 0.1°F can be indicated by meter or graphic means. Infrared theory and instrumentation are based upon radiation from a blackbody; therefore, **emissivity correction** must be made electrically in the test instrument or arithmetically from instrument readings.

ACOUSTIC SIGNATURE ANALYSIS

Acoustic signature analysis involves the analysis of sound energy emitted from an object to determine characteristics of the object. The object may be a simple casting or a complex manufacturing system. A passive test is one in which **sonic** energy is transmitted into the object. In this case, a mode of resonance is usually detected to correlate with cracks or structure variations, which cause a change in effective modulus of the object, such as a nodular iron casting. An active test is one in which the object emits sound as a result of being struck or as a result of being in operation. In this case, characteristics of the object may be correlated to damping time of the sound energy or to the presence or absence of a certain frequency of sound energy. Bearing wear in rotating machinery can often be detected prior to actual failure, for example. More complex analytical systems can monitor and control manufacturing processes, based upon analysis of emitted sound energy.

Acoustic emission is a technology distinctly separate from acoustic signature analysis and is one in which strain produces bursts of energy in an object. These are detected by **ultrasonic** transducers coupled to the object. Growth of microcracks, and other flaws, as well as incipient failure, is monitored by counting the pulses of energy from the object or recording the time rate of the pulses of energy in the ultrasonic range (usually a discrete frequency between 1 kHz and 1 MHz).

5.5 EXPERIMENTAL STRESS AND STRAIN ANALYSIS

by Gary L. Cloud

REFERENCES: Cloud, *Optical Methods of Engineering Analysis,* revised second printing, Cambridge University Press, New York, 1998. Experimental stress and strain analysis, otherwise called **experimental mechanics,** is the quantitative measurement of the response of bodies and structures to stimuli, often in the form of applied loads. Applications of experimental mechanics are numerous and include, e.g., biomechanics, geomechanics, fracture mechanics, infrastructure, materials characterization, manufacturing processes, transducer design, motion analysis, mechanical design, and nondestructive testing.

Many problems faced by analysts and designers stretch the limitations of analytical and numerical techniques, so experimental solutions are needed. Hybrid approaches wherein experimental data are used as input to a numerical solution that is later subjected to experimental validation are becoming more commonplace. The major problem that must be faced in measurement of strain in structures is that, for most engineering materials, the strain induced by loads is very small, the change in length per unit gage length being on the order of parts per million (microstrain), so a sensitivity of 1 to 10 microstrain is required. A direct way to measure stress does not exist, except, possibly, by photoelasticity. To determine stress, the strain must be measured and converted to stress by use of the stress-strain relations for the material.

Many techniques are available to attack problems in experimental mechanics, and engineers should be familiar with a spectrum of methods so that the most appropriate one for a given situation might be chosen. Some techniques have evolved, through long usage, into well-known standard approaches, while others are evolving or have not yet been thoroughly accepted by industrial practitioners. The former class includes resistance strain gages, photoelasticity, geometric moiré, and brittle coatings. Those less known or still in evolution include holographic interferometry, speckle interferometry, speckle shearography, acoustic emission, thermography, digital photoelasticity, digital image correlation, and moiré interferometry. This section describes in

some detail three of the standard methods and the basic functions of several of the more advanced methods. Systems, supplies, information, and software for implementing these techniques are available from vendors.

RESISTANCE STRAIN GAGES

A resistance strain gage consists of a length of a fine conducting wire or foil, often configured as a grid, that is intimately attached to the specimen. As the specimen is deformed, the gage is deformed by the same amount, so that its resistance changes. If the relationship between resistance change and strain is known for the gage material, then the observed resistance change can be converted to specimen strain at the gage location. The relationship between strain and resistance change is

$$\varepsilon = \frac{1}{F}\left(\frac{\Delta R}{R}\right)$$

where ε is the strain along the gage axis, R is the gage resistance, ΔR is the change of gage resistance with strain, and F is the **gage factor** for the given gage. Gage factor F is determined by the gage manufacturer through batch testing in a known uniaxial stress field and is provided to the gage user, as is the gage resistance.

Strain gages are employed in two distinct ways. First, they are used for direct measurement of strain. Second, they are commonly used in transducing devices in which strain measurements are used as indicators of some other physical parameter such as load, pressure, or acceleration.

Strain gages of many types, sizes, and configurations are available. The most common type is the **bonded metallic gage** in which the sensing element is a thin foil that is mounted on a plastic substrate. Strain gages must be carefully selected for an application in accordance with manufacturers' recommendations. Perfect bonding between gage and specimen is necessary, and rigorous but simple cleaning, bonding, wiring, and protective coating practices must be followed.

Gage factors for common metallic gages are about 2; so since the strain is small, the resistance change per unit gage resistance is also small. An important part of a strain gage installation is the **interface circuit** that converts the small resistance change to a voltage that can be amplified and measured. Two basic interface circuits are commonly used, usually with additions that add capability and flexibility.

Wheatstone Bridge The Wheatstone bridge interface circuit is shown in Fig. 5.5.1. In the usual unbalanced operational mode, the variable resistor R_2 is first adjusted to give 0-V signal output E_O. Then as the resistance of the gage R_1 is changed by ΔR_1, the signal voltage changes proportionately. Often, more than one of and perhaps all the resistors in the circuit are strain gages. For four identical active gages and where E is the supply voltage and F is the gage factor, the relationship between output voltage and gage strains is

$$E_O = \frac{EF}{4}(-\varepsilon_1 + \varepsilon_2 - \varepsilon_3 + \varepsilon_4)$$

This voltage is usually amplified and recorded by a voltmeter, an oscilloscope, or a digital DAQ system. Dedicated strain gage readout devices

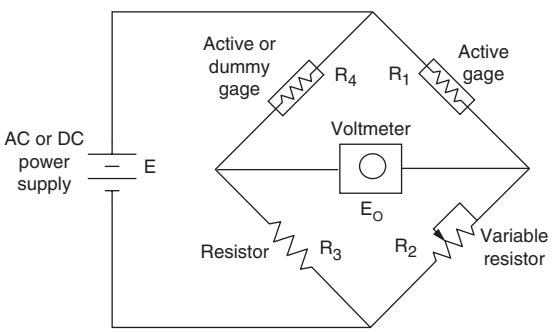

Fig. 5.5.1 Wheatstone bridge circuit for resistance strain gages.

and/or the use of circuit calibration allows direct indication in strain units. The output signal is proportional to the excitation voltage applied to the bridge, so a stable power supply must be used to limit noise and to maintain constant circuit sensitivity. Either dc or ac excitation can be used; the latter facilitates the use of filtering and carrier amplification to reduce noise.

An advantage of the bridge circuit is that more than one active strain gage can be used to multiply output or to cancel unwanted inputs such as temperature effects. For example, consider the case where surface strain in a beam is to be measured. Two gages can be used. The one on the top of the beam might be subjected to tensile strain, and the one on the bottom will experience compressive strain. The gages are wired into the bridge circuit in adjacent arms, e.g., R_1 and R_4. The bridge output will then be twice what will be seen if only one gage is used. Any effect of axial loads on the beam will be canceled as will temperature effects, because they have the same sign. The unbalanced bridge circuit can be used to measure either static or dynamic strain. It is the most widely used basic circuit, being implemented with many extra features in most commercial strain indicators and DAQ systems.

Potentiometer Circuit The potentiometer circuit, also called the ballast circuit or the voltage divider circuit, is shown in its basic form in Fig. 5.5.2. This circuit is particularly simple to fabricate. The function of the ballast resistor in the circuit is to limit the current through the strain gage while still giving usable output. Usually, this circuit is used with only one strain gage, so care must be taken that unwanted inputs, such as temperature effects, are eliminated in other ways.

A disadvantage of the potentiometer circuit is that there is no way to initially balance it so that the starting output voltage is zero. The small

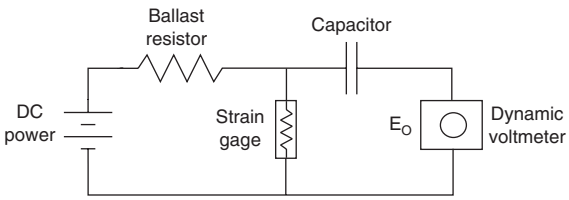

Fig. 5.5.2 Potentiometer circuit for resistance strain gages.

change in output voltage that is caused by the strain gage will be superimposed on a relatively large bias voltage, meaning that one is faced with the problem of measuring accurately the small change in a large quantity. This fact limits the use of the circuit to problems involving rapidly varying or **dynamic strains.** A capacitor placed in the circuit acts as a high-pass filter so as to block the steady bias voltage and pass the time-varying component of interest to an amplifier. The circuit is dc-powered, and the power supply must be stable and noise-free. In spite of these limitations, this circuit is exceptionally useful and easy to use, e.g., in measuring strains in machinery.

Circuit Calibration The output equations for the interface circuits are useful for basic design of the measuring system, but not for accurate calibration of the entire system for measuring strain. This calibration is best accomplished by creating a known resistance change at the input. Implementation involves placing a large shunt calibration resistor R_{cal} in parallel with the strain gage R_g. The equivalent calibration strain ε_{cal} is given by

$$\varepsilon_{\text{cal}} = \frac{1}{F}\left(\frac{R_g}{R_g + R_{\text{cal}}}\right)$$

The relationship between circuit observable output (e.g., oscilloscope trace deflection) and input strain is thus established.

Temperature Effects Strain gages exhibit a resistance change with temperature that cannot be distinguished from the effects of strain. Large errors can result if the gage temperature changes during an experiment and steps are not taken to eliminate these errors. Two approaches are used singly or together.

Manufacturers of strain gages provide gages that are self-compensated for broad classes of materials (e.g., brass, steel). These gages can be

used without any other temperature compensation with good, but not perfect, results. They are especially useful for single-gage applications over short periods of time where mechanical strains are relatively large.

The output voltage equation for the Wheatstone bridge can be exploited to eliminate temperature effects in two related ways. In the first, an inactive dummy gage that is the same as the active gage is mounted on an unstressed coupon of the same material. It is wired into an arm of the circuit adjacent to the measuring gage. False strains from temperature are canceled. Another approach is to design the experiment so that two active measuring gages are placed in adjacent bridge arms. The desired strain signal is multiplied, and the false thermal strain is eliminated. Similar approaches are used to eliminate temperature effects on gage lead wires, leading, e.g., to the familiar "three-wire hookup" for single-gage installations.

Transverse Sensitivity Resistance strain gages exhibit sensitivity to the strain component that is perpendicular to the gage axis. If the stress field is uniaxial, this transverse sensitivity does not cause errors because the gage factor is determined in such a field. In any other biaxial stress field, ignoring the effects of transverse sensitivity can lead to errors that range from negligible to very large, depending on the nature of the field and the strain component being measured. The **transverse sensitivity** K_T is determined by the gage manufacturer by batch testing and is provided to the gage user. For typical foil gages, K_T is less than 2 percent.

The errors caused by transverse sensitivity are eliminated by using two gages in a biaxial stress field, even if only one strain component is sought. That is, for accurate determination of one strain in an unknown biaxial stress field, two gages are required. The two gages are mounted perpendicular to each other. Usually the gages are identical. The common gage factor F as given by the manufacturer is set on the strain indicator. The strain indicator gives an apparent strain for each gage, but the readings are not true strains. The readings are corrected as follows. Let the apparent indicated strain for gage A be Q_A and the reading for the second gage B be Q_B. The true or actual strain ε_A along the axis of gage A is

$$\varepsilon_A = \frac{1 - \mu_0 K_T}{1 - K_T^2}(Q_A - K_T Q_B)$$

Note that if $Q_B \gg Q_A$, the error caused by ignoring K_T will be large. The μ_0 in the equation is the Poisson ratio for the material that was used by the manufacturer in determining the gage factor and the transverse sensitivity factor. It is not always available, but may be taken to be 0.285 with reasonable safety. The true strain for gage B is found by permuting the subscripts in the above equation.

Strain Rosettes In a general biaxial strain field, there are three unknowns—the two principal strains and the orientations of the principal strain axes. If complete knowledge of the field is sought, then three strain measurements are required. Strain gages do not respond to shear strain, so three determinations of normal strain are used. Three ordinary gages can be employed, but gage manufacturers provide standard combinations of gages, called strain rosettes, that contain two or more gage elements in a single package which can be applied just as a single gage would. The two most common configurations of gage elements in rosettes are (1) the **rectangular rosette,** having gage elements at 0°, 45°, and 90°, and (2) the **delta (equiangular) rosette,** having elements at 0°, 60°, and 120°.

The analysis of rosette data involves the strain transformation equations and the transverse sensitivity correction that are described above. Consider the case in which a strain-indicating system is used, so the output is in strain units. Set the usual manufacturer's gage factor F on the instrument. Take Q_n to be the apparent strain reading from gage n. The true strain for gage n is ε_n. Recall that the transverse sensitivity of each gage is K_T. The true strains for each gage element in the rectangular rosette are then found to be $\varepsilon_1 = Q_1 - K_T Q_3$; $\varepsilon_2 = (1 + K_T)Q_2 - K_T(Q_1 + Q_3)$; $\varepsilon_3 = Q_3 - K_T Q_1$. If gage elements 1 and 3 establish an xy coordinate system, then the strain transformation equations yield $\varepsilon_x = \varepsilon_1$, $\varepsilon_y = \varepsilon_3$, and shear strain $\varepsilon_{xy} = \varepsilon_1 + \varepsilon_3 - 2\varepsilon_2$. With strains in the xy coordinate system known, the principal strains and the principal axes can be found from the transformation equations or Mohr's circle. Similar data reduction equations for other types of rosettes are easily found in basic strain gage literature.

Strain Gage Transducers Resistance strain gages are used extensively in constructing transducers to measure physical quantities such as force, torque, pressure, and acceleration. Simple devices of this type can be easily fabricated in the lab for specific applications, or they may be purchased. As an example, consider the situation mentioned above in which two gages are mounted on the top and bottom of a beam to measure the strain in the beam. If the output of the circuitry is calibrated in terms of the load on the beam, then the device becomes a load-measuring transducer. Likewise, a common wrench is instrumented with strain gages and calibrated so that the output is indicative of the torque transmitted by the wrench.

Critical factors in designing such transducers involve the design of the elastic member such that the physical quantity to be measured is converted to a detectable strain, the proper mounting of the gages to detect the strain, the design of the circuit so that it responds to the quantity of interest and rejects unwanted inputs, and the calibration of the device.

Because the strain in the elastic member is not of quantitative interest in a transducer, circuit calibration is not useful or appropriate. Instead, direct calibration is accomplished by applying known values of the desired physical quantity to the transducer and relating these known values to the output. For example, if a beam is used as a load transducer, then known dead weights are applied to the beam. The circuit output is then adjusted to indicate directly the values of the applied known load.

GEOMETRIC MOIRÉ

The geometric moiré or **mechanical moiré** effect is the mechanical occlusion of light by superimposed patterns to produce another pattern that is called a **moiré fringe pattern.** It is not an optical interference effect. Geometric moiré provides a basis for a family of methods for measuring deformation, strain, shape, and contour. Advanced moiré methods, including moiré interferometry, are easily understood if the principles of geometric moiré are known.

This section describes the basic moiré phenomenon and its implementation for measurement of displacement and strain in a deformable body. Then two techniques for using moiré to perform measurements of out-of-plane shape and deformation are outlined.

In-Plane Moiré Figure 5.5.3 illustrates the basic moiré phenomenon that appears when one system of closely spaced straight lines, a grill, is laid over a similar set. The two sets have different line spacings, and one set is also rotated slightly with respect to the other. At certain locations, the lines from one set block the gaps in the other set so that no light is allowed through. If the line spacings are sufficiently small, then the areas where the light is blocked appear to join up to form another system of broad lines, called a moiré fringe pattern. Simple experimentation with

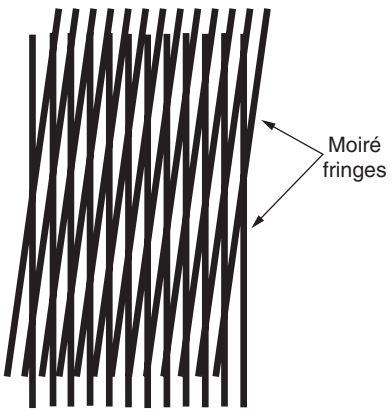

Fig. 5.5.3 Moiré effect from superimposing two line arrays.

such a system shows that the moiré fringes undergo large movement when one of the grills is shifted only a small amount relative to the other grill. Clearly, the moiré pattern is a motion magnifier that can be exploited to give sensitive measurements of relative motion.

Figure 5.5.4 shows a cross-sectional view of how the moiré effect is used to measure displacement and strain. Light is projected through two grills that were originally identical but that now have slightly different

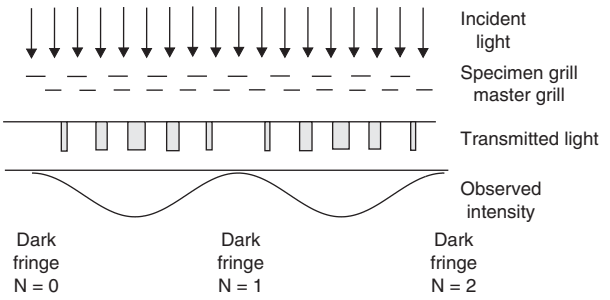

Fig. 5.5.4 Moiré effect as used for displacement measurement.

spacings because one grill has been stretched relative to the other. Consider that this grill, called the specimen grill, has been stretched so that 10 lines fill the space occupied by 12 lines on the second grill, called the master grill. The widths of the cracks between the lines of the gratings vary slowly from zero to a maximum. Recall that the grill lines are actually close together, so the eye or camera does not see the light passing through the individual cracks; rather, local averages are seen. The local average seems to oscillate twice from dark to light in the space shown, meaning 2 orders of moiré fringes are present. The extension or stretch in the specimen grill is $u = Np$, where N is the moiré fringe order and p is the line spacing or pitch of the master grill. Applying the strain-displacement relationship results in the following:

$$\varepsilon = \frac{\partial u}{\partial x} = \frac{\partial (Np)}{\partial x} = p\frac{\partial N}{\partial x}$$

which means that the strain along an axis perpendicular to the grill lines is the grill pitch times the gradient of the moiré fringe order (or fringe spacings) along the same axis. Similar relationships can be derived for strain in other directions and for the shear strain, so the complete strain map over the extent of the specimen can be determined. Fringes caused by small relative rotations of the grills are oriented perpendicular to the grating lines, so they do not affect the measurement of normal strain.

Specimen and Master Gratings Grills or gratings must be attached to the surface of the specimen and superimposed with a master grating using one of several observing techniques. For measurement of strain in metals, the gratings must be very fine, having about 10 to 100 lines per millimetre. A considerable body of art and technology has developed for creating and attaching specimen gratings. Superb photographically reproduced gratings for moiré work are available from vendors. Another good approach is to obtain fine photomechanical screens that are used by the printing industry. These screens are available as photographic negatives or as fine metallic mesh. They may be cut up and glued to the specimen using techniques similar to those used for attaching strain gages. More commonly, the purchased gratings are kept as intact masters and are copied onto the specimen and as submaster gratings by photographic contact printing, by stencil techniques, or by vacuum deposition. Contact printing into a thin coating of the photoresist that is used for making printed circuit boards has been a method of choice for many practitioners.

Observing Techniques A direct and simple method of measuring displacements and strains in flat specimens involves the use of a transparent model. A grill or grating is attached or printed onto the specimen surface. The specimen is mounted in the loading frame, and a master grill is put into direct contact with the specimen grill and initially oriented to bring the moiré fringe orders to a minimum. The master grating is held in position with, e.g., a spring clothespin. A camera set up at some distance from the specimen-master combination is used to photograph the moiré fringes as the specimen is loaded.

If a nontransparent specimen is used, the specimen grating must be made to have high visibility in reflected light. The direct superposition method can still be used, but fringe visibility will suffer. An alternative viewing method is to image the specimen grating in the back of a view camera. The master grating replaces the ground glass in the camera back, and the moiré pattern will be visible there. Direct photography of the specimen grating provides two other approaches. The first approach is to use double exposure, one exposure before loading and the other after loading. The moiré fringe pattern is then contained in the photograph. The second approach is to photograph the specimen grating for each loading state. These photographic replicas can be superimposed directly with a submaster or with each other at any later time, which is often an advantage in dealing with nonreversible processes, e.g., those involving plastic deformation. A disadvantage of any procedure that involves imaging of the specimen grating is that the optical system must be capable of resolving finely spaced lines and very accurate focus must be established. Even so, the moiré fringes might not be of good contrast. In these cases, optical Fourier processing can be implemented to improve fringe visibility and reduce noise, while offering the possibility of enhancing strain sensitivity. Figure 5.5.5 shows a moiré fringe pattern obtained with these techniques.

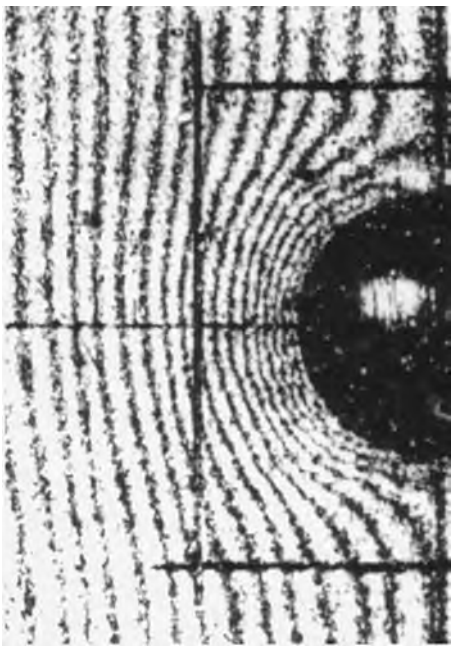

Fig. 5.5.5 Portion of moiré pattern for measuring strain near a plastically deformed hole in aluminum.

Data Reduction The objective is to create a map of strain distribution from a moiré fringe pattern, so the derivative of the moiré fringe order with respect to position coordinates must be found. Conceptually, this is easily done by drawing an array of axes across the fringe pattern with the axes oriented perpendicular to the grill direction. The location of each moiré fringe pattern relative to some fiducial origin along a chosen axis is measured and plotted as fringe order versus distance in specimen space. This graph is differentiated to obtain the fringe gradient, which is then multiplied by the grill pitch to obtain normal strain as a function of position along the axis. The process is repeated for each of the axes to complete the strain map. Fringe digitization and computer processing are useful, but manual processing serves well for small jobs, since only local fringe spacings are required.

Shadow Moiré The shadow method of geometric moiré utilizes the superimposition of a master grating with its own shadow. The fringes are loci of constant out-of-plane elevation, so they form an absolute contour map of the object being examined. This method and related laser scanning techniques are used, e.g., in manufacturing and medical diagnosis.

To create a shadow moiré pattern, a master grill or grating of pitch p is placed in front of the specimen object. For large objects, the master grating can be created by stretching strings across a frame. The combination is illuminated with a collimated beam at incidence angle α. Observation is at normal incidence by means of a field lens that focuses the light to a point, at which is placed a camera that is focused on the object. The incident illumination creates a shadow of the grating on the surface of the specimen. The grating shadows on the specimen are elongated or foreshortened by a factor that depends on the inclination of the surface, and they are shifted laterally by an amount that depends on the incidence angle and the distance w from the master grating to the specimen. The camera superimposes the image of the master grating with its own distorted shadow, thereby forming a moiré fringe pattern. The fringes are numbered from some origin. If N is the moiré fringe order, then the elevation is $w = Np/\tan\alpha$.

Projection Moiré Another useful method for using moiré for out-of-plane displacement measurement or determining changes of contour, as opposed to absolute contour, involves projecting the reference grating onto the specimen by means of, e.g., a slide projector. This method is especially useful when the shapes of two objects must be compared, a situation that arises in, e.g., examining sheet metal stampings. An advantage is that only a small transparency of the specimen grating is required. Alternatively, a projected grating can be created by oblique interference of collimated beams of coherent light. Another advantage is that changes of contour are determined directly, and subtraction of absolute contours is not required. A disadvantage is that the imaging system must be able to resolve the individual grating lines, as with double-exposure in-plane moiré.

To create the fringe pattern, the grating is projected at incidence angle α onto the specimen surface in its initial state, or onto a master reference surface. The projected grating image is photographed by a camera along the normal to the surface. The specimen is then distorted, or else the second surface is inserted if contour difference is sought. This grating is photographed over the first image. The developed double-exposure image will contain moiré fringes that are numbered as usual. At any point in the image where the moiré fringe order is N, the elevation difference w between the two states of the specimen is given by $w = Np/\sin\alpha$.

OPTICAL INTERFEROMETRY

Many important methods of experimental mechanics are based on the phenomenon of optical interference. Approaches in this class include, e.g., photoelasticity, hologram interferometry, speckle interferometry, and moiré interferometry. Brief study of interference, one of the cornerstones of optics along with diffraction, facilitates quick understanding and use of all such methods.

Collinear Interference Light is considered to be electromagnetic waves that are characterized by an electric vector that oscillates in time and space. The magnitude of the electric vector may be taken to be a simple harmonic plane wave described as $E = A\cos(2\pi/\lambda)(z - vt)$, where A is amplitude, λ is the wavelength of the light, z is the distance along the optical path, v is the wave velocity, and t is time. Consider two waves that are of equal amplitude, identically polarized and *coherent,* meaning that they originate from the same source, such as a laser. These two waves travel along the same path, but one of the waves leads the other by some distance or phase difference r. The two waves will interfere with each other to produce a resultant wave whose intensity I is a function of the phase difference; $I = 4A^2\cos^2(\pi r/\lambda)$.

The phase lag between two light waves, which is not visible to the eye or detectable by any other means, is converted, through the interference process, to an intensity difference, which can be measured. The transformation of invisible phase difference to visible intensity difference is the basis of all interferometry methods of measurement. It allows determination of physical quantities such as motion to within a fraction of the wavelength of light, giving sensitivities on the order of a few nanometres.

Generic Interferometer Figure 5.5.6 shows a conceptual model that contains all the important elements of an interferometric system for measurement. Light comes from a coherent source such as a laser and is split into two parts by a **beam splitter.** The two waves have identical phases as they leave this component, but they travel along different optical paths, one or both of which might contain optical elements or specimens. The two waves are out of phase as they are directed into a **combiner,** where they interfere to produce an intensity that depends on the **phase difference.** A **detector** such as a photocell, an eye, or a camera records the intensity, from which the phase difference can be inferred. The phase difference is indicative of the difference in *optical path lengths* between the two paths.

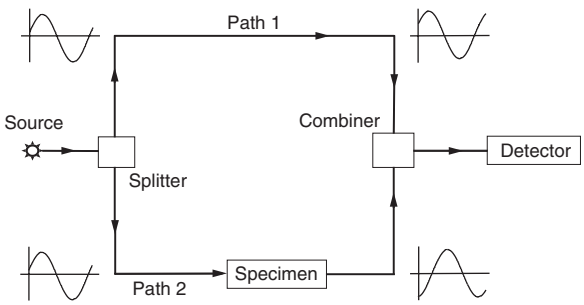

Fig. 5.5.6 The generic interferometer model.

The conceptual model seems to imply that only pointwise measurements can be made with one wave, but the process can be executed for every point in a broad field simultaneously if a beam of light is used and appropriate optical elements such as lenses, mirrors, and imaging devices are employed. The interference process produces a map of light and dark patches, called **interference fringes,** that are superimposed on the image of the object being studied. This whole-field capability is a great strength of optical methods in general.

Interferometry can be employed in various modes. The generic model suggests that the difference between the two paths can be obtained directly with one observation. More commonly, one path is held constant, and two observations are taken for two different states of the specimen path. When they are subtracted, the change in only the specimen path is determined.

PHOTOELASTIC STRESS ANALYSIS

Photoelastic stress analysis is a method whereby **polarized light** is used to obtain, through interferometry, the stress state in a loaded transparent model or in a coating that is glued to the surface of a prototype.

Stress Birefringence The speed of light in a vacuum is divided by the speed of light in a material to give the **refractive index** of the material. Optical path length is the physical path length (distance) traveled times the index of refraction. Changes or differences in optical path length cause phase lags or retardations in optical waves as they traverse a material.

In certain materials, including many plastics, the index of refraction at any point is closely related to the state of stress at that point, and such materials are said to exhibit stress birefringence. Experiments on these materials show that

1. The index of refraction depends on the plane of polarization of light that passes through the material; i.e., the index is direction-dependent.
2. The state of the index of refraction can be described in terms of principal values that are associated with principal directions.

3. The principal values of the refractive index are proportional to the principal stresses.

4. The principal axes of refractive index coincide with the principal stress axes.

A conclusion is that if the directions and magnitudes of the principal refractive indexes can be ascertained, then the principal stresses and principal directions can be determined, provided that the relation between stress and refractive index is known for the material. Determination of stress by interferometric observation of refractive index changes is accomplished by the method of photoelasticity.

Photoelasticity Experiment and theory show that **birefringent materials** can transmit light only if the light is polarized in the principal directions. If a polarized wave falls on a birefringent material, it is immediately divided into two polarized components, one in each principal direction, so the beam splitter function that is necessary for interferometry is served by the surface of the birefringent material. The two waves created traverse the material at differing speeds, depending on the two principal values of the refractive index. As these two waves exit the material, one will lag behind the other by an amount which is called the **relative retardation** R that depends on the local principal stresses and a material stress-optic coefficient C_σ according to the equation $R = C_\sigma(\sigma_1 - \sigma_2)d$, where σ_1 and σ_2 are the principal stresses and d is the thickness of the specimen. Figure 5.5.7 illustrates this process. To determine R, the two wave components must be recombined interferometrically. This task is accomplished by a second polarizer in the system, known as the analyzer, which extracts the portion of each wave that lies parallel to the transmission axis of the analyzer to create the conditions for collinear interference. The intensity produced through interference is directly related to the relative retardation as described above.

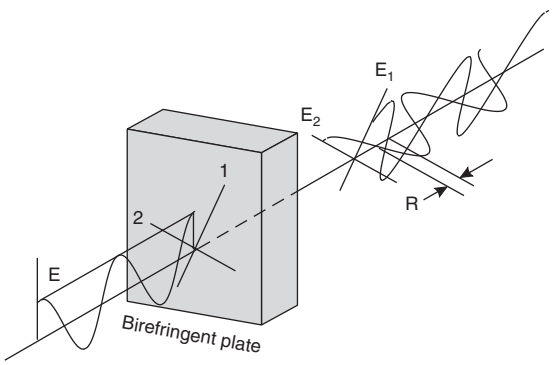

Fig. 5.5.7 Effect of birefringent plate on incident polarized light.

If this interferometric process occurs simultaneously over the entire field and a photograph is made of the result, **interference fringes** will be observed. Attention for the moment is limited to the case in which the polarization axis for the light entering the specimen is perpendicular to the analyzer axis. For linear polarization, two separate families of fringes are produced, as shown in Fig. 5.5.8. These families are

1. Isochromatic fringes that are loci of points having constant relative retardation R, meaning they are lines of constant $\sigma_1 - \sigma_2$. From the isochromatic family, the magnitudes of stress in the specimen can be found.

2. Isoclinic fringes that are loci of points where the principal stress axes are parallel to the axes of the polarizer and analyzer. This family is used to establish the principal stress directions for the entire specimen.

Circular Polarization A problem with the photoelastic measurements described above is that an isoclinic fringe always masks some of the isochromatics. The isoclinics can be eliminated by inserting two quarter-wave plates into the system, one on either side of the specimen.

A quarter-wave plate is a birefringent slab that produces a quarter-wavelength of relative retardation over its extent. The plates are inserted into the photoelastic measuring system with their principal axes

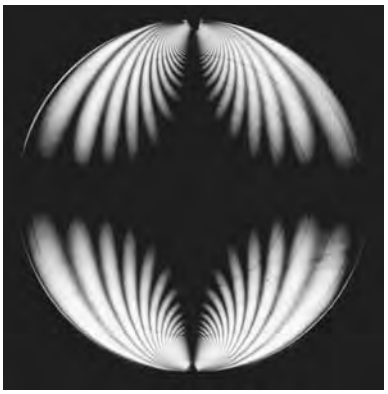

Fig. 5.5.8 Isoclinic and isochromatic fringes in compressed disk.

oriented at ±45° to the crossed axes of the polarizer and analyzer. The entering plane-polarized wave is divided into two equal orthogonal components, and upon exit from the quarter-wave plate, one component will lag behind the other by λ/4. The resultant of the two out-of-phase waves will describe a circular helix in space, hence the term **circularly polarized.** The physical effect of using circular polarization is that the directional dependence of the interference is removed. The second λ/4 plate essentially cancels the effect of the first one, but does not restore the directional dependence.

Photoelastic Polariscope A combination of optical devices that is used for photoelasticity is called a polariscope. Many polariscope configurations are used. One setup, called the diffused-light polariscope, is shown in Fig. 5.5.9. In this system, a diffuser scatters light in all directions, only some of which passes through the system parallel to the optical axis. The polarizer, quarter-wave plates, specimen, and analyzer are arranged as described above. These elements are usually mounted in calibrated rings so that they can be rotated relative to one another and to the specimen. A field lens is used to direct the light to a point, where a camera lens is placed to create an image of the specimen on film or a CCD array. The distance from the field lens to the camera aperture must be made equal to the focal length of the field lens; otherwise, the image is made with light that has not traveled parallel to the optical axis, and errors will be introduced. For quantitative measurements, a narrowband color filter is used to create nearly monochromatic light (single wavelength), and/or a spectral lamp is used as the light source.

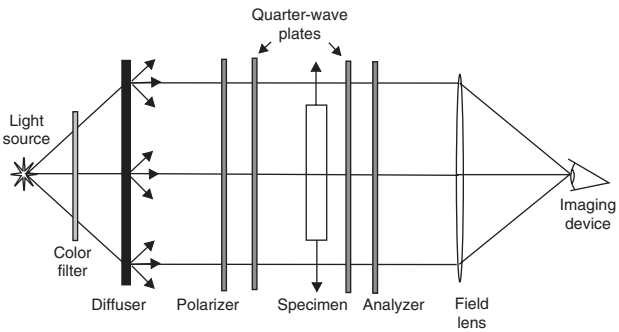

Fig. 5.5.9 Diffused-light photoelastic polariscope.

Material Calibration Accurate determination of the **stress-optic coefficient** C_σ for the photoelastic model material is prerequisite to good quantitative results. Calibration is accomplished by testing a model in which the stress field is known, such as a tensile specimen, a beam in pure bending, or a disc in diametral compression. The simple tension test is the most generally valid, since the stress state in tension does not depend on any assumptions of linearity. The coefficient is dependent not only on the material, but also on time and wavelength,

and these factors must be taken into account. Several different calibration procedures are valid; only a basic one is described here.

A "dog bone" specimen of the model material is placed in a loading frame within the polariscope. A load is applied, and the isochromatic order in the central section is carefully estimated by direct observation at a certain time t_1, say 10 min, after load. The load is increased by an increment, and the isochromatic order again is estimated at t_1 after the load increase. The process is repeated for several loads, with the fringe order being determined always at the same time after changing the load. A plot of fringe order versus stress in the tensile specimen is constructed. The slope of this plot gives the stress-optic coefficient for time t_1 after load.

When the unknown specimen of the same material is tested to determine its stress state, the isochromatic orders are recorded for the same time t_1 after loading that was used in the calibration. Sometimes this is not possible. To avoid repeating the calibration testing, the isochromatic orders are often observed at a sequence of times after load so that a family of calibration results is obtained. Note that the definition of stress-optic coefficient is not standardized. Care is required in using calibration data provided by others.

Recording and Interpreting Isochromatics The specimen and polariscope are arranged as described above, first with the polarizer and analyzer axes crossed. The quarter-wave plates are also crossed, and their axes are set to produce circularly polarized light. No light transits the system, so this setup is known as the **dark-field** arrangement. The specimen is loaded, and after waiting the prescribed time, the isochromatics are photographed. Immediately, the analyzer is rotated by 90° so as to produce a **light-field** arrangement, meaning that the background around the specimen will be bright. The new light-field isochromatic pattern is photographed. The reason that both light-field and dark-field patterns are recorded is that twice as many data are obtained, which aids in interpretation. A typical dark-field pattern is shown in Fig. 5.5.10.

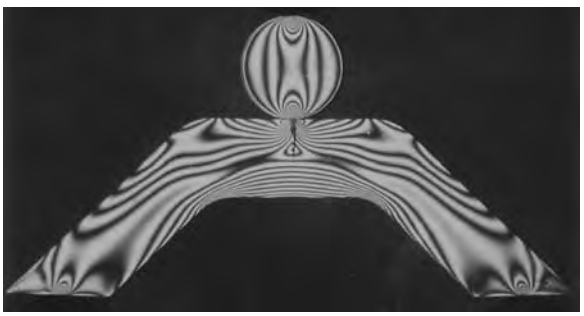

Fig. 5.5.10 Isochromatic pattern indicating stresses in compressed disk and arch.

The dark fringes in the dark-field picture are whole-order isochromatics along which the relative retardation is an integral multiple of the wavelength. The isochromatics are numbered in order. Assigning correct orders is not a trivial task. One good technique is to keep track of them as the load is applied. Along these whole-order fringes, the relationship between stress and fringe order is found by combining equations already presented, to give

$$\sigma_1 - \sigma_2 = 2\tau_{\max} = \frac{m\lambda}{C_\sigma d}$$

where m is the fringe order. The dark fringes in the light-field photograph are half-order isochromatics that lie between the whole orders.

The **isochromatic fringes** give for every point inside the specimen only the difference between the principal stresses, which is the diameter of Mohr's circle and equals twice the maximum shear stress. Many methods to obtain the individual stresses have been devised. The problem is simplified along a boundary where there is no load and $\sigma_2 = 0$. For practical purposes, a **boundary stress plot** can be constructed to show stress concentrations. Normals to the boundary are erected with their lengths proportional to the local σ_1, and the tips of the normals are connected with a smooth curve.

Often, interpolation between whole and half orders of isochromatics does not give sufficient precision for critical areas. One of several precise methods of determining fractional fringe orders must then be used.

Recording and Interpreting Isoclinics For observation of isoclinics, a second model of a material that is optically less sensitive than that used for isochromatic study is often employed so that the isochromatic orders will be small and not mixed with the isoclinics. The model is placed in the polariscope, the quarter-wave plates are removed, and the polarizer and analyzer are set so their axes are horizontal and vertical, as are the axes of the specimen. The 0° isoclinic fringe appears, and it is recorded and labeled. Recording of isoclinics can be accomplished by direct tracing from a view camera back or a video monitor. They can also be photographed if heavy exposures are used to narrow the fringes.

The polarizer and analyzer are then rotated by an increment of, say, 10° in the same direction, and the isoclinic for that setting is recorded and labeled. This process is repeated incrementally until 90° is reached, where the isoclinic will duplicate the first one. The direction of rotation of the polarizers is arbitrary, but the direction used must be noted, usually on the isoclinic tracing. The result will be a complete pattern of isoclinic fringes that show the principal directions everywhere in the specimen.

Visualizing the stress direction map from the isoclinics is rather difficult, so an overlay orthogonal network of lines that are everywhere tangent to the principal directions, called the **stress trajectory map,** is often constructed from the isoclinic pattern.

Scaling Stresses from Model to Prototype To use stresses obtained from a photoelasticity model, they must be transferred to the prototype component or structure, which likely is of a different material, of a different size, and subjected to different loads.

Two aspects of the problem must be given attention: the difference of material properties and the differences in size and load. If the component being studied is elastic, simply connected (no holes), or multiply connected (with holes) with no unequilibrated forces on a single boundary, and if the body forces are negligible, and if no displacement boundary conditions apply, then the stress distribution is completely independent of material properties. If displacement conditions are specified, then the modulus of elasticity is important. For the other cases, only the Poisson ratio is a factor, and the error in ignoring this effect will not exceed about 7 percent. In other words, for most problems, material properties are not a factor in transferring measured stresses from model to prototype.

The laws of dimensional similitude, developed from the Buckingham theorem, are used to attend to size and load differences. The resulting laws of dimensional similarity are almost intuitively obvious. Geometric similarity requires that the model be only scaled up or down relative to the prototype, meaning its shape and proportions cannot change. A similar rule applies for load similarity; the ratios of like loads between model and prototype must be constant. If displacement boundary conditions are specified, then the absolute load magnitudes must be scaled also, but this case rarely arises. If the similarity conditions are satisfied, then the stresses in model and prototype satisfy the following relationship, which shows how the stresses are scaled,

$$\sigma_p = \sigma_m \left(\frac{P_p}{P_m}\right)\left(\frac{a_m}{a_p}\right)\left(\frac{d_m}{d_p}\right)$$

where subscript m means model and subscript p means prototype. Here P_p/P_m is the **load scale factor,** a_m/a_p is the **dimension scale factor,** and d_m/d_p is the **thickness scale factor.** This relationship applies only to two-dimensional problems, and it allows the thickness to be conveniently scaled differently from the lateral dimensions.

Reflection Photoelasticity The strain distribution in nontransparent prototype components and structures can be determined by an extension of the photoelasticity methods described above. The method requires that a thin layer of birefringent material be attached to the surface of the component, using a cement that contains a light-scattering medium

such as aluminum powder. The polariscope is then folded in the middle. The polarized light (circular or linear) falls on the photoelastic coating and undergoes a relative retardation as it traverses the coating twice. The scattered (reflected) light travels through the second quarter-wave plate and the analyzer to the eye or a camera. As the prototype is loaded, isoclinic and isochromatic fringes will be obtained.

Interpretation of isochromatic fringes differs from before in that the surface strains, not stresses, are transferred to the birefringent coating by the cement. The material is calibrated in terms of principal strains, and the isochromatics are so interpreted. If stress data are required, then the prototype material properties and the stress-strain relations are used.

Reflection photoelasticity is highly developed because of its practicality, especially in the industrial setting.

Three-Dimensional Photoelasticity Photoelasticity can be employed to determine stress states in three-dimensional objects by several techniques. All such methods basically slice the three-dimensional model into a stack of two-dimensional cases. Two such approaches are described briefly here.

The **embedded polariscope technique** uses a thin slice cut from the birefringent model. The slice is then glued back into the model, with polarizer and quarter-wave sheets replacing the saw kerfs. The result is a polariscope encased within the object with what is essentially a two-dimensional model between the polarizers. The model is loaded, and the fringe patterns for the slice are obtained by passing unpolarized light through the model. Studies have shown that cutting the model and gluing it back together with the polarizers in place does not significantly affect the stress state if care is taken to use a matching cement. This method works very well for obtaining the stresses in the plane of a single slice of the object.

The **stress freezing and slicing method** requires that the model be brought to its second-order transition point by careful heating. A small deformation is then applied by loading, and this deformation is maintained while the model is cooled. The model is permanently deformed, and the birefringence, which is related to the strains in this case, is "locked in." The model can be sliced into two-dimensional cases for study in an ordinary polariscope without affecting the strain state. Again, the principal stress components in the plane of each slice are obtained. Additional observations, as by oblique incidence, are needed to completely characterize the three-dimensional state of stress.

HOLOGRAPHIC INTERFEROMETRY

Holography is a method of storing and regenerating all the amplitude and phase information contained in the light that is scattered from a body that has been illuminated by a laser. Because all the information is reproduced, the reconstructed object beam is, ideally, indistinguishable from the original, so a full three-dimensional image is created. Since it is possible to record the exact shape and position of the body in two different states, it is possible to compare the two records interferometrically to obtain precise measurement of movement or deformation. This measurement technique is called holographic interferometry.

The making of a hologram is by oblique interference of two beams. The setup for creating this interference follows the model of the generic interferometer described above. A laser beam is split into two parts. One part, called the reference beam, is expanded and made to fall on a high-resolution photographic plate or film. The other part, called the object beam, is expanded and made to illuminate the object being studied. The object scatters this illumination, so some of it falls on the same photographic film. The reference and object beams interfere at the film to create a very fine complex grating, which is stored in the film emulsion. It can be shown that this grating contains all information about the object shape, size, and position, although there will be no recognizable image stored.

Reconstruction of the holographic image is through diffraction by the exposed and developed film. The film is placed back into its original position and illuminated by only the reference beam. Grating diffraction will divide the beam into three parts, one of which, in the usual setup, recreates the object beam. If the eye is placed to receive this beam, a perfect virtual image of the object will appear in its original state.

Holographic interferometry is implemented in three different ways. In the double-exposure method, also called the **frozen-fringe technique,** the initial state of the specimen is recorded as outlined above, but the film is not developed at this point. The object is then loaded or moved, and a second exposure of the object is recorded on the same film. The film is developed and replaced in the setup so as to reconstruct the images. The two superimposed images will be seen as one, and it will contain interferometric fringes that indicate the deformation or motion of the specimen. Alternative approaches are the **real-time (live fringe) technique** and **time-average technique** for vibrating objects, neither of which is treated here.

Holographic interferometry is primarily used for nondestructive testing of, e.g., tires and turbine components. In this application, subsurface voids, disbonds, and damage cause local perturbations in the otherwise smooth holographic fringes.

SPECKLE INTERFEROMETRY

The technique offers a way to achieve interferometric sensitivities for very rapid, whole-field, noncontacting measurements of displacement and strain. No special specimen preparation is required, and video imaging can be utilized.

The basic phenomenon employed in this class of techniques is that an object viewed or photographed when illuminated with laser light will exhibit a dense pattern of bright and dark granular spots. This pattern is called a speckle pattern, and it is caused by local interference of the many waves that are scattered from every point on the illuminated object and that subsequently fall on the receiving sensor array. In order that the speckles have correct properties for measurement of deformation, two beams must be mixed at the sensor. In the first case, a reference beam is used as in holography. In the second instance, two object beams are used.

To utilize these speckles in electronic or digital speckle interferometry, a first digital image is captured to computer memory. The specimen is then moved or deformed, and a second image is recorded. The second digital image is subtracted from the first, pixel by pixel. This subtraction of two intensity patterns can be done in real time on a desktop computer. The resulting video image will exhibit fringes that indicate the local displacements of the surface of the specimen.

If a reference beam is used, if the illuminated object is photographed at near-normal incidence, and if the object beam is nearly parallel with the reference beam at the sensor, then the fringes indicate only the out-of-plane motion of the object. If two object beams are used, then they are set up to illuminate the object at equal and opposite angles of incidence, and viewing is along the normal. In this case, the fringes correspond to in-plane motion or deformation. The measured in-plane displacements are then locally differentiated to obtain strain distribution.

The speckle methods just described produce speckle correlation fringes that are most commonly used in qualitative applications such as nondestructive testing. Phase-shifting techniques extend the method for quantitative measurement. A common implementation is to incorporate into one of the optical paths a mirror that can be moved by small amounts so as to change that path length. At least three images are captured for a matching number of different path length differences. Processing yields a whole-field phase change map that indicates both the sign and the magnitude of displacement. The displacement map is locally differentiated in the computer. Thus, whole-field strain measurements with high sensitivity and small gage lengths can be accomplished in only a few seconds.

SPECKLE SHEAROGRAPHY

This approach uses the speckle effect described above in a different way but with much of the same equipment. An extra optical element, such as a Fresnel biprism or a split lens, creates two images of the object, one very slightly displaced from the other, on the camera sensor. A first image pair is captured, the specimen is loaded, and the second image pair is captured and subtracted from the first, typically in real time. The resulting image pair exhibits fringes that indicate the in-plane derivative

of the out-of-plane displacement (i.e., the change in slope), at each point of the object surface.

Electronic speckle shearography may be made highly quantitative by use of phase shifting as outlined above, but it is primarily used without phase shifting as a very important nondestructive evaluation tool that is simple, quick, and easy to implement. As with holographic interferometry, the presence of flaws is indicated by local perturbations of the otherwise smooth fringe pattern.

MOIRÉ INTERFEROMETRY

To implement this extension of the moiré method, a grating having spatial frequencies on the order of several hundreds of lines per millimetre is created by oblique interference of two collimated laser beams. This grating is transferred to the surface of the specimen by one of several techniques. The specimen is then replaced in the same setup that was used to make the grating, and the specimen is loaded. Reflective diffraction of the incident beams from the specimen grating creates two slightly diverging beams, where the local divergence angle is related to the local change of spatial frequency of the specimen grating that is caused by strain. The two diffracted beams are collected by a camera lens and brought together to form two coincident images that appear as one. This image will contain interference fringes resulting from local oblique interference. Interpretation of the fringe pattern is the same as for geometric moiré. This important method overcomes the sensitivity limitation of geometric moiré. Its main disadvantage is that significant specimen preparation is required.

DIGITAL IMAGE CORRELATION

Digital image correlation (DIC) is a noncontacting measurement method that uses digital signal processing algorithms to track the motion in the image plane of subsets of either a coherent or an incoherent random speckle pattern. Two-dimensional DIC (2D-DIC) uses a single camera to convert images of a nominally planar object that deforms predominantly in-plane into a full field of in-plane displacements (u, v). Three-dimensional DIC (3D-DIC) converts images obtained from cameras located at multiple viewpoints into a full field of the actual, three-dimensional displacements (u, v, w) of all points in a planar or nonplanar object. Both methods require that a calibration process be performed so that the image motions are converted to displacements with optimal accuracy. The process can be performed either before or after completion of the experiment. When photographic-quality lenses are used to acquire images, calibration in 2D-DIC is relatively simple, requiring only an image of a ruler or similar metric object. For 3D-DIC using photographic-quality lenses, pairs of images of a calibration object undergoing a set of 3D rotations are required to obtain the orientations and positions of the cameras.

THERMOELASTICITY

Thermoelasticity is a noncontacting analysis technique that utilizes the minute local changes of temperature that are caused by stress. When a body is subjected to tensile stress, the temperature of the body reduces slightly; conversely, when the stress is compressive, a slight increase in temperature occurs. In the elastic regime, this temperature change is directly proportional to the change in the sum of principal stresses on the component surface. The only surface preparation required is to ensure uniform emissivity of the component surface at the infrared wavelengths used by the detector, and this requirement can usually be met by the application of a thin layer of matte black paint. Since the detectors are measuring photon emission from a surface, the technique can also be used obliquely, with satisfactory results obtainable at up to 60° from the normal to the surface.

5.6 MECHANICS OF COMPOSITE MATERIALS

This section deals with some of the basic issues that must be addressed in applying the classic methods of mechanics of materials to predict the mechanical behavior of **fiber-reinforced composite** materials. The section deals exclusively with the mechanical behavior of materials that consist of stiff and strong **fibers,** such as glass, carbon, or aramid, embedded in a softer material, such as a thermosetting or thermoplastic polymer, known as the matrix material, or simply, the **matrix.** The role of the fiber is to carry the load, while the role of the matrix is to keep the fibers aligned, transfer the load from fiber to fiber, and protect the fibers from direct mechanical contact and exposure to environmental factor. Other fibers, such as boron, have been employed, and composite materials that use metal, such as aluminum or titanium, for the matrix have been developed. Composite materials that utilize boron fibers or a metal matrix are much less common and are quite expensive. The mechanical behavior of metal matrix composite materials can differ significantly from that of polymer matrix composite materials in that metals yield before failing, whereas the polymers used in composite materials are brittle by comparison and generally fail by cracking. This difference in the two matrix materials can lead to different failure criteria and therefore different analysis techniques to predict whether a particular structural component will fail or not. Here emphasis will be on polymer matrix composite materials. However, some of the assumptions and calculations are applicable to metal matrix composite materials if the stresses in the matrix are below the yield level.

The application of the classical methods of the mechanics of materials to the analysis and design of structural components such as beams, plates, curved panels, and cylinders fabricated from fiber-reinforced composite materials requires considerably more steps than the analysis and design of a similar components made of conventional materials such as aluminum or steel. The primary reasons for this are (1) the layered nature of components fabricated of fiber-reinforced composite materials and (2) the fact that fibers in the layers result in stiffness and strength properties that are directionally dependent, not only for that layer, but also for the overall structural component. When material behavior is not directionally dependent, the material behavior is said to be *isotropic.* Except for slight rolling or other effects due to fabrication

or consolidation, which are generally ignored, conventional materials such as aluminum or steel exhibit isotropic behavior. When material properties are directionally dependent, material behavior is said to be *anisotropic,* or nonisotropic. There are special classes of anisotropic material behavior, and one which will be defined shortly is *orthotropic* material behavior. To reach a point where the only two differences between a component fabricated from a fiber-reinforced composite material and one fabricated from a conventional material are the layered nature and anisotropic behavior, several steps and assumptions have to be considered. Specifically, the fiber and matrix materials each have their own stiffness and strength properties. When these two constituents are combined, the resulting mixture, or composite, has its own stiffness and strength properties, called **composite properties.** Composite properties depend not only on the properties of each constituent, but also on the quantity of each constituent in the composite material. A key measure of the quantity of a constituent is the **volume fraction** of that constituent in a given volume of composite material. There are models for predicting the properties of a composite material based on the properties and volume fraction of each constituent, in particular, the volume fraction of fibers and the volume fraction of matrix material. These models are referred to as **micromechanical models.** Several micromechanical models will be introduced here for computing such properties as overall stiffness or the overall thermal expansion properties of a layer of composite material. These models are based on assumptions regarding the mechanical behavior of the individual fibers, the matrix surrounding them, and importantly, assumptions regarding the interaction between the fibers and matrix. The result is a collection of models each with its own assumptions and each representing the combined stiffness and thermal expansion effects of all the fibers and the accompanying matrix material. A layer of composite material is assumed to exhibit these combined effects, and it is assumed the combined effects are uniformly distributed throughout the volume of the layer. The assumption of having a uniform distribution of composite properties, despite the fibers and matrix having individual properties, is the concept of **homogenization,** or **smearing,** of constituent properties. Once the smeared composite properties are predicted, the individual fibers and the matrix material lose their identities and a layer is treated as a single material with a single set of properties. Each layer may have different properties, because one layer may use glass fibers and another layer may use carbon fibers, or there may be a mixture of glass and carbon fibers within one layer; but within a layer, the properties are assumed to be uniform. Homogenization is an important concept. If this concept were not accepted, it would be impossible to study the mechanical behavior of fiber-reinforced composite materials, as it would be an insurmountable task to keep track of the behavior of each fiber and the matrix material surrounding each fiber.

After the effects of the fibers and matrix have been homogenized, before design and analysis can proceed, the concept of homogenization must be utilized a second time to represent the combined effects of all the layers on the overall behavior of a structural component. This second step is necessary because a component could be constructed of many, many layers of material. The assemblage of all the layers is referred to as a **laminate.** It becomes a large chore to keep track of the behavior of each layer in a laminate when interest may center on the overall behavior of the laminated component, e.g., such as its lowest natural frequency or its buckling load. The steps for homogenization at this level also depend on assumptions regarding the behavior of the individual layers and assumptions regarding how each layer interacts with the surrounding layers. The study of the individual layers in a laminate and how they interact is often referred to as **macromechanics.** The behavior of a laminate when loading, support, and other conditions are considered is often referred to as **composite structural mechanics.** Many of the tools of mechanics apply to composite materials and structures because the tools are based on principles that do not depend on material behavior. Ultimately, however, material properties must be defined, and it is at this step that the design and analysis of composite structures and of isotropic structures diverge.

MICROMECHANICS OF A LAYER

The practice of using fiber and matrix properties to estimate the homogenized response of a composite material has received lots of attention, and some treatment is given in almost all introductory composite materials texts. Practical reasons for such an investigation include the ability to perform tradeoff studies, such as varying the amount and type of fiber used, and the ability to estimate, during the initial design process, quantities that are difficult to determine experimentally. Three principal approaches have been employed in developing these models for homogenization: (1) mechanics of materials techniques, (2) elasticity solutions, and (3) empirical or semiempirical techniques. In the mechanics of materials approaches, simplified geometries and simplified material behavior models are usually employed. In general, these models do not capture the details of the stress and strain distributions within the fiber and matrix, and as a result, details of the actual fiber arrangement within the composite are unimportant. In the elasticity solutions, an attempt is made to determine the actual stresses and strains in the fiber and matrix materials, and as a result, the fiber packing arrangement within the composite becomes important. In such a case, the actual fiber packing is often represented by idealized packings, as shown in Fig. 5.6.1.

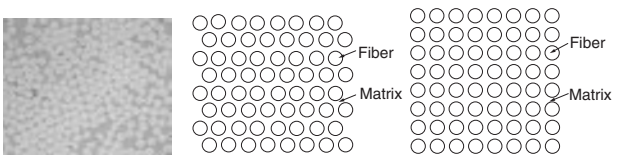

Fig. 5.6.1 Photomicrograph of actual composite cross section (left), and idealized representations of fiber packing: hexagonal (center) and square (right).

It is important to keep in mind, however, that these models are estimates of the actual material behavior, and that there is no substitute for direct experimental measurement of the desired properties. As a result, the models presented in this section are selected for the balance between ease of use and accuracy.

Before we discuss the micromechanics models in detail, it is necessary to begin with a description of the thermal-mechanical response of a single layer of unidirectional composite material. In discussing this response, it is convenient to use an orthogonal coordinate system that has one axis aligned with the direction of the fiber reinforcement, a second axis that lies in the plane of the layer, and a third axis through the thickness of the layer, as illustrated in Fig. 5.6.2. Such a coordinate system is referred to as the **principal material coordinate system** (or often the 1-2-3 coordinate system). In this case, the 1 direction is the fiber direction, while the 2 and 3 directions are transverse directions, often

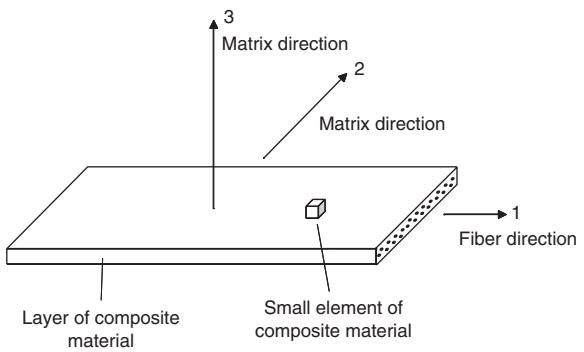

Fig. 5.6.2 Layer of composite material illustrating principal material coordinate system.

referred to as matrix directions. At this point, it is clear that the material properties will not be the same in all directions. For example, it is reasonable to expect the composite to be stronger and stiffer in the 1 direction than in either the 2 or 3 directions. It might also be expected that the 2 and 3 directions have similar—but not necessarily identical—properties because they are both directions perpendicular to the fiber direction. Accordingly, the response of an element of material at a point within the

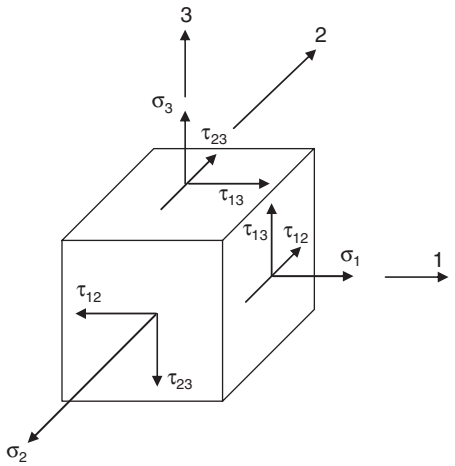

Fig. 5.6.3 Illustration of stresses acting on the small element of composite material from Fig. 5.6.2.

layer that has different properties in the different directions is to be described. Such an element can be acted on by six stress components, as shown in Fig. 5.6.3.

In Fig. 5.6.3, σ_1, σ_2, and σ_3 are the normal stresses, in the principal material directions; τ_{12} is the in-plane shear stress; and τ_{13} and τ_{23} are through-thickness shear stresses. The corresponding normal strains are given as ε_1, ε_2, and ε_3; the engineering shear strains are given as γ_{12}, γ_{13}, and γ_{23}. The strains can then be related to the stresses as

$$\begin{Bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \varepsilon_3 \\ \gamma_{23} \\ \gamma_{13} \\ \gamma_{12} \end{Bmatrix} = \begin{bmatrix} \frac{1}{E_1} & -\frac{\nu_{21}}{E_2} & -\frac{\nu_{31}}{E_3} & 0 & 0 & 0 \\ -\frac{\nu_{12}}{E_1} & \frac{1}{E_2} & -\frac{\nu_{32}}{E_3} & 0 & 0 & 0 \\ -\frac{\nu_{13}}{E_1} & -\frac{\nu_{23}}{E_2} & \frac{1}{E_3} & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{1}{G_{23}} & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{1}{G_{13}} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{1}{G_{12}} \end{bmatrix} \begin{Bmatrix} \sigma_1 \\ \sigma_2 \\ \sigma_3 \\ \tau_{23} \\ \tau_{13} \\ \tau_{12} \end{Bmatrix} \tag{5.6.1}$$

In Eq. (5.6.1), E_1 is the extensional modulus in the fiber direction, E_2 is the extensional modulus in the transverse 2 direction, and E_3 is the extensional modulus in the transverse 3 direction of the composite material. Poisson's ratios ν_{ij} are defined so that $-(\nu_{ij}/E_i)\sigma_i$ is the strain in the j direction due to a stress applied in the i direction. The three shear moduli are G_{23}, G_{13}, and G_{12}. The extensional moduli, the shear moduli, and Poisson's ratios are collectively referred to as *engineering properties*. The square 6-by-6 matrix in Eq. (5.6.1) is referred to as the **compliance matrix** and is normally denoted by S. The stress-strain relations, in terms of S, are then given as

$$\begin{Bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \varepsilon_3 \\ \gamma_{23} \\ \gamma_{13} \\ \gamma_{12} \end{Bmatrix} = \begin{bmatrix} S_{11} & S_{12} & S_{13} & 0 & 0 & 0 \\ S_{21} & S_{22} & S_{23} & 0 & 0 & 0 \\ S_{31} & S_{32} & S_{33} & 0 & 0 & 0 \\ 0 & 0 & 0 & S_{44} & 0 & 0 \\ 0 & 0 & 0 & 0 & S_{55} & 0 \\ 0 & 0 & 0 & 0 & 0 & S_{66} \end{bmatrix} \begin{Bmatrix} \sigma_1 \\ \sigma_2 \\ \sigma_3 \\ \tau_{23} \\ \tau_{13} \\ \tau_{12} \end{Bmatrix} \tag{5.6.2}$$

A direct comparison of Eqs. (5.6.1) and (5.6.2) shows that the compliances may be calculated in terms of the engineering properties as

$$\begin{aligned} S_{11} &= \frac{1}{E_1} & S_{12} &= -\frac{\nu_{21}}{E_2} & S_{13} &= -\frac{\nu_{31}}{E_3} \\ S_{21} &= -\frac{\nu_{12}}{E_1} & S_{22} &= \frac{1}{E_2} & S_{23} &= -\frac{\nu_{32}}{E_3} \\ S_{31} &= -\frac{\nu_{13}}{E_1} & S_{32} &= -\frac{\nu_{23}}{E_2} & S_{33} &= \frac{1}{E_3} \\ S_{44} &= \frac{1}{G_{23}} & S_{55} &= \frac{1}{G_{13}} & S_{66} &= \frac{1}{G_{12}} \end{aligned} \tag{5.6.3}$$

The inverse of the compliance matrix is called the **stiffness matrix** and is normally denoted by C. Once this inverse has been defined, the stress-strain relations can be written as

$$\begin{Bmatrix} \sigma_1 \\ \sigma_2 \\ \sigma_3 \\ \tau_{23} \\ \tau_{13} \\ \tau_{12} \end{Bmatrix} = \begin{bmatrix} C_{11} & C_{12} & C_{13} & 0 & 0 & 0 \\ C_{21} & C_{22} & C_{23} & 0 & 0 & 0 \\ C_{31} & C_{32} & C_{33} & 0 & 0 & 0 \\ 0 & 0 & 0 & C_{44} & 0 & 0 \\ 0 & 0 & 0 & 0 & C_{55} & 0 \\ 0 & 0 & 0 & 0 & 0 & C_{66} \end{bmatrix} \begin{Bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \varepsilon_3 \\ \gamma_{23} \\ \gamma_{13} \\ \gamma_{12} \end{Bmatrix} \tag{5.6.4}$$

The forms of Eqs. (5.6.2) and (5.6.4) suggest that 12 compliance or 12 stiffness components are required to describe the stress-strain response of an element of composite material. However, it can be shown that the compliance matrix is symmetric, i.e., $S_{ij} = S_{ji}$. For that to be true, from Eq. (5.6.3) the following relations must hold:

$$\frac{\nu_{12}}{E_1} = \frac{\nu_{21}}{E_2} \qquad \frac{\nu_{13}}{E_1} = \frac{\nu_{31}}{E_3} \qquad \frac{\nu_{23}}{E_2} = \frac{\nu_{32}}{E_3} \tag{5.6.5}$$

The relations in Eq. (5.6.5) are referred to as the **reciprocity relations.** Thus, only nine independent engineering properties are needed to describe the elastic response of a layer of composite material.

In addition to the strains due to the stresses, expansional strains due to temperature changes and moisture absorption are often present. For such a case, the strains are related to the stresses by a modification of Eq. (5.6.1) as

$$\begin{Bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \varepsilon_3 \\ \gamma_{23} \\ \gamma_{13} \\ \gamma_{12} \end{Bmatrix} = \begin{bmatrix} \frac{1}{E_1} & -\frac{\nu_{21}}{E_2} & -\frac{\nu_{31}}{E_3} & 0 & 0 & 0 \\ -\frac{\nu_{12}}{E_1} & \frac{1}{E_2} & -\frac{\nu_{32}}{E_3} & 0 & 0 & 0 \\ -\frac{\nu_{13}}{E_1} & -\frac{\nu_{23}}{E_2} & \frac{1}{E_3} & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{1}{G_{23}} & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{1}{G_{13}} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{1}{G_{12}} \end{bmatrix} \begin{Bmatrix} \sigma_1 \\ \sigma_2 \\ \sigma_3 \\ \tau_{23} \\ \tau_{13} \\ \tau_{12} \end{Bmatrix} + \begin{Bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \\ 0 \\ 0 \\ 0 \end{Bmatrix} \Delta T + \begin{Bmatrix} \beta_1 \\ \beta_2 \\ \beta_3 \\ 0 \\ 0 \\ 0 \end{Bmatrix} \Delta M \tag{5.6.6}$$

In the above equation, α_1,α_2, and α_3 are coefficients of thermal expansion; β_1, β_2, and β_3 are coefficients of moisture expansion; ΔT is the change in temperature from a reference temperature; and ΔM is the change in moisture content within the material from a reference moisture content. (This reference moisture content is normally taken as zero.) Note that there are no thermally induced or moisture-induced shear strains in the principal material coordinate system. The form of the stress-strain relations in Eq. (5.6.6), and Eqs. (5.6.1), (5.6.2), and (5.6.4), defines **orthotropic material** behavior. Such behavior is characterized by (1) a decoupling of shear and normal responses, resulting in many of the off-diagonal terms being zero, and (2) different material properties in the three mutually perpendicular directions. Specifically, the 0s represent the fact that with orthotropic material behavior, normal strains and normal stresses are related; each particular shear strain is related to the corresponding shear stress, but there are no relations between normal strains and shear stresses, or between shear strains and normal stresses. Also, as noted, there are no thermal- or moisture-induced shear strains. The form of the stress-strain relations for isotropic materials is the same as the form of Eq. (5.6.6), the difference being that the material properties are the same in all directions, and only two engineering properties are needed (e.g., the extensional modulus E and Poisson's ratio ν) to fully describe the response. That is, for the engineering properties $E_1 = E_2 = E_3 = E$, $\nu_{23} = \nu_{13} = \nu_{12} = \nu$, $G_{23} = G_{13} = G_{12} = G = E/2(1 + \nu)$, while for the expansional properties $\alpha_1 = \alpha_2 = \alpha_3 = \alpha$ and $\beta_1 = \beta_2 = \beta_3 = \beta$.

Equation (5.6.6) represents the general response of a layer of composite material subjected to a three-dimensional stress state. In many practical situations involving the use of composite materials, it may be assumed that the composite is in a state of *plane stress,* a state in which three of the stress components are so much smaller than the other three that they may be assumed to be equal to zero for subsequent stress analysis. Some situations in which the plane-stress assumption may be employed arise when you are considering beams, plates, and cylinders in which one dimension is at least an order of magnitude greater than the other dimensions. As an example, consider a plate in which the thickness direction, which is aligned with the 3 direction, is much less than the in-plane dimensions. The out-of-plane stress components σ_3, τ_{23}, and τ_{13} will then be much smaller than the in-plane stress components σ_1, σ_2, and τ_{12}. As a result, Eq. (5.6.6) can be simplified considerably.

Before we examine the simplified stress-strain relations for the case of a plane stress state, a number of cautions are in order. First, the plane stress assumption can lead to inaccuracies. For example, delamination of laminates often initiates at free edges due to the presence of out-of-plane stresses—exactly the stress components ignored in a plane stress analysis. Second, locations of discontinuities in structures, such as at bonded joints, stiffeners, or ply drops, result in three-dimensional stress states. Finally, in many cases the through-thickness stresses are quite small in comparison to the in-plane stresses (particularly σ_1), but may still be large enough in comparison to the corresponding strength values that failure may occur.

To see why the plane stress assumption is important, the effects of this assumption on the stress-strain relations given in Eq. (5.6.6) can be examined. For the case of plane stress in which σ_3, τ_{23}, and τ_{13} are taken to be identically zero, the stress-strain relationship reduces to

$$\begin{Bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \gamma_{12} \end{Bmatrix} = \begin{bmatrix} \frac{1}{E_1} & -\frac{\nu_{12}}{E_1} & 0 \\ -\frac{\nu_{12}}{E_1} & \frac{1}{E_2} & 0 \\ 0 & 0 & \frac{1}{G_{12}} \end{bmatrix} \begin{Bmatrix} \sigma_1 \\ \sigma_2 \\ \tau_{12} \end{Bmatrix} + \begin{Bmatrix} \alpha_1 \\ \alpha_2 \\ 0 \end{Bmatrix} \Delta T + \begin{Bmatrix} \beta_1 \\ \beta_2 \\ 0 \end{Bmatrix} \Delta M \tag{5.6.7}$$

The 3-by-3 matrix is referred to as the **reduced compliance matrix,** although the expressions for the elements of the reduced compliance matrix in terms of the engineering properties are identical to those in the full 6-by-6 compliance matrix. In addition, it is important to remember that while the normal stress σ_3 is equal to zero for the plane stress condition, the corresponding normal strain ε_3 is nonzero and is given by

$$\varepsilon_3 = -\frac{\nu_{13}}{E_1}\sigma_1 - \frac{\nu_{23}}{E_2}\sigma_2 + \alpha_3 \Delta T + \beta_3 \Delta M \tag{5.6.8}$$

Thus, to analyze the plane stress response of a layer of composite material to mechanical, thermal, and moisture loads, it is necessary to determine four engineering properties as well as the in-plane coefficients of thermal and moisture expansion. To determine these, the approach taken is to make use of models based primarily on the mechanics of materials, and use other models when the mechanics of materials models do not yield results of sufficient accuracy (or when the more accurate models result in expressions nearly as simple as the mechanics of materials results).

The basic starting point for the mechanics of materials model is the representative volume element shown in Fig. 5.6.4. This volume element consists of enough fiber and matrix that the volume fraction of fiber within the volume is the same as the average value in the composite. A model for the fiber-direction extensional modulus E_1 can be developed by assuming that when a load is applied in the 1 direction, the strains in the fiber and matrix are the same. This **isostrain** assumption leads to the result

$$E_1 = V_f E_1^f + (1 - V_f)E_1^m \tag{5.6.9}$$

where V_f is the fiber volume fraction, E_1^f is the extensional modulus of the fiber along its length (the 1 direction), and E_1^m is the matrix extensional modulus in the 1 direction. Equation (5.6.9) is often referred to as the **rule-of-mixtures (ROM) model** for E_1 because the result is simply the fractional amount of fiber multiplied by the fiber extensional modulus added to the fractional amount of matrix multiplied by its extensional modulus. Likewise, if an isostrain model is used to estimate Poisson's ratio of the composite material, the resulting expression is

$$\nu_{12} = V_f \nu_{12}^f + (1 - V_f)\nu_{12}^m \tag{5.6.10}$$

where ν_{12}^f is the fiber Poisson ratio and ν_{12}^m is Poisson's ratio of the matrix. Despite representing a round fiber with a square cross section, numerical results to be presented later in this section will justify recommending the use of rule-of-mixtures estimates for E_1 and ν_{12}.

An inspection of the representative volume shown in Fig. 5.6.4 reveals that the isostrain assumption is not appropriate for estimating the extensional modulus E_2. Rather, a first estimate would be that the

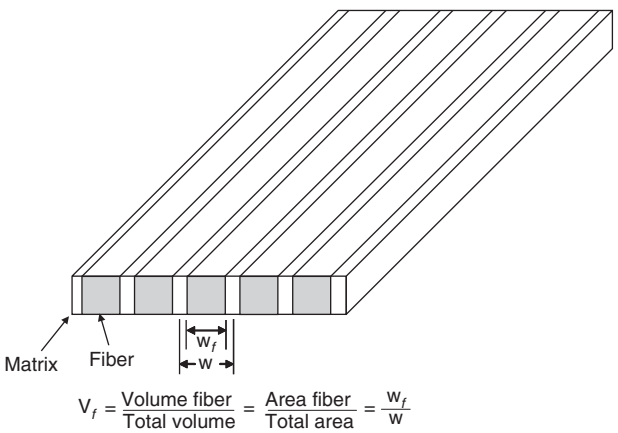

Fig. 5.6.4 Representative volume element for micromechanics analysis.

stress σ_2 is the same in the fiber and the matrix, and is uniform, when a transverse load is applied. This **isostress assumption** results in an estimate for E_2 of the composite given by

$$\frac{1}{E_2} = \frac{V_f}{E_2^f} + \frac{1 - V_f}{E_2^m} \tag{5.6.11}$$

where E_2^f and E_2^m are the fiber and matrix transverse extensional modulus values, respectively. While this result based on the isostress assumption is often presented in introductory composite materials textbooks, it produces relatively inaccurate results, as will be shown later. An improved estimate may be developed by considering the representative volume element shown in Fig. 5.6.5. The analysis of this unit element is conducted by assuming that the central fiber/matrix element has an effective extensional modulus that may be calculated by using the rule of mixtures. From there, an analysis of the deformation of the total element leads to the result

$$\frac{1}{E_2} = \frac{1 - \sqrt{V_f}}{E_2^m} + \frac{\sqrt{V_f}}{E_2^f\sqrt{V_f} + E_2^m(1 - \sqrt{V_f})} \tag{5.6.12}$$

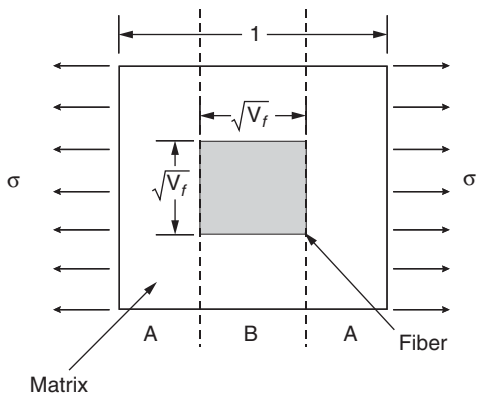

Fig. 5.6.5 Representative volume element for improved mechanics of materials model.

This **improved mechanics of materials model** yields results that are in much better agreement with exact elasticity analyses than those in Eq. (5.6.11), and it is the recommended model for calculating E_2.

For the case of shear loading, the simple mechanics of materials analysis with an isostress assumption gives

$$\frac{1}{G_{12}} = \frac{V_f}{G_{12}^f} + \frac{1 - V_f}{G_{12}^m} \tag{5.6.13}$$

As with the composite extensional modulus in the 2 direction, often referred to as the transverse extensional modulus, this isostress model gives poor estimates of the composite shear modulus G_{12}. It is possible to develop an analogous expression to Eq. (5.6.12) for the shear modulus. However, there is an **approximate elasticity solution** for a simplified geometry (concentric cylinders of fiber and matrix) available in closed form. The resulting expression for the composite shear modulus is

$$G_{12} = G_{12}^m \frac{(G_{12}^m + G_{12}^f) - V_f(G_{12}^m - G_{12}^f)}{(G_{12}^m + G_{12}^f) + V_f(G_{12}^m - G_{12}^f)} \tag{5.6.14}$$

This model gives results that are extremely accurate in comparison to exact results for hexagonally and square-packed arrays of fibers.

In addition to these models that describe the response of a layer of composite materials to mechanical loading conditions, it is often useful to have micromechanics models for the expansional coefficients [such as the thermal expansion coefficients and moisture expansion coefficients that appear in Eq. (5.6.7)]. By using the mechanics of materials representative volume element of Fig. 5.6.4, it is possible to develop expressions for the coefficient of thermal expansion in the 1 direction α_1 as

$$\alpha_1 = \frac{\alpha_1^f E_1^f V_f + \alpha_1^m E_1^m (1 - V_f)}{E_1^f V_f + E_1^m (1 - V_f)} \tag{5.6.15}$$

The expression for the coefficient of moisture expansion β_1 is developed by analogy. The coefficient of thermal expansion in the 2 direction α_2 is given by

$$\alpha_2 = \left[\alpha_2^f - \left(\frac{E_1^m}{E_1}\right)\nu_{12}^f(\alpha_1^m - \alpha_1^f)(1 - V_f)\right]V_f + \left[\alpha_2^m + \left(\frac{E_1^f}{E_1}\right)\nu_{12}^m(\alpha_1^m - \alpha_1^f)V_f\right](1 - V_f) \tag{5.6.16}$$

where E_1 is the rule-of-mixtures expression for the fiber direction extensional modulus given by Eq. (5.6.9). Once again the coefficient of moisture expansion in the 2 direction may be developed by analogy.

In addition to the mechanics of materials, improved mechanics of materials, and elasticity models described above, semiempirical models have been developed for calculating engineering properties of a layer based upon fiber and matrix properties. The most widely used are the **Halpin-Tsai equations**

$$\frac{M}{M_m} = \frac{1 + \eta\xi V_f}{1 - \eta V_f} \tag{5.6.17}$$

in which

$$\eta = \frac{M_f/M_m - 1}{M_f/M_m + \xi} \tag{5.6.18}$$

where M = composite modulus E_2 or G_{12}
M_f = corresponding fiber modulus E_2^f or G_{12}^f
M_m = corresponding matrix modulus E_m or ν_m

and ξ is a parameter having admissible values $0 \leq \xi < \infty$, which may be different for E_2 and G_{12}. A simplified form of Eqs. (5.6.17) and (5.6.18), obtained by substitution of Eq. (5.6.18) into Eq. (5.6.17), is given by

$$M = M_m \frac{(M_f + \xi M_m) - \xi V_f(M_m - M_f)}{(M_f + \xi M_m) + V_f(M_m - M_f)} \tag{5.6.19}$$

A value of $\xi = 1$ gives excellent results for G_{12}—an identical result to that given by Eq. (5.6.14). A value of $\xi = 2$ has been found to give good results for E_2.

An assessment of the accuracy of each of the models presented in this section may be obtained by comparing the results from these simple models to results from exact elasticity solutions. Such a comparison requires properties for the fiber and matrix materials. Representative properties for glass fibers, graphite fibers, and polymer matrix materials are taken as the values given in Table 5.6.1. Tables 5.6.2 and 5.6.3

Table 5.6.1 Representative Properties for Graphite Fiber, Glass Fiber, and Polymeric Matrix Materials

	Graphite fiber	Glass fiber*	Polymer matrix*
E_1 (GPa)	233	73.1	4.62
E_2 (GPa)	23.1	73.1	4.62
G_{12} (GPa)	8.96	30.0	1.699
ν_{12}	0.200	0.22	0.36
α_1 (/°C)	-0.540×10^{-6}	5.04×10^{-6}	41.4×10^{-6}
α_2 (/°C)	10.10×10^{-6}	5.04×10^{-6}	41.4×10^{-6}

* Assumed to be isotropic.

provide a comparison of composite properties as a function of fiber volume fraction using the various relations discussed.

EXAMPLE 1. Evaluate the engineering and thermal expansion properties of a layer of glass-fiber-reinforced polymer having a fiber volume fraction of 60 percent.

APPROACH. Make use of the properties given in Table 5.6.1 along with the micromechanics models described above.

SOLUTION. The fiber properties are obtained from Table 5.6.1 as

$$\begin{aligned} E_1^f &= E_2^f = 73.1\,\text{GPa} \\ G_{12}^f &= 30.0\,\text{GPa} \\ \nu_{12}^f &= 0.22 \\ \alpha_1^f &= \alpha_2^f = 5.04 \times 10^{-6}/°\text{C} \end{aligned}$$

The matrix properties are obtained from Table 5.6.1 as

$$\begin{aligned} E_1^m &= E_2^m = 4.62\,\text{GPa} \\ G_{12}^m &= 1.699\,\text{GPa} \\ \nu_{12}^m &= 0.36 \\ \alpha_1^m &= \alpha_2^m = 41.4 \times 10^{-6}/°\text{C} \end{aligned}$$

The fiber volume fraction is given as $V_f = 0.60$.

For E_1, using Eq. (5.6.9),

$$\begin{aligned} E_1 &= V_f E_1^f + (1 - V_f)E_1^m \\ &= (0.60)(73.1) + (1 - 0.60)(4.62) \\ &= 45.7\,\text{GPa} \end{aligned}$$

This value compares favorably with the exact value of 45.7 GPa found by using an elasticity solution (see Table 5.6.3).

For ν_{12}, using Eq. (5.6.10),

$$\begin{aligned} \nu_{12} &= V_f \nu_{12}^f + (1 - V_f)\nu_{12}^m \\ &= (0.60)(0.22) + (1 - 0.60)(0.36) \\ &= 0.276 \end{aligned}$$

This value compares favorably with the exact value of 0.269 found by using an elasticity solution (see Table 5.6.3).

For E_2, using Eq. (5.6.11),

$$\begin{aligned} \frac{1}{E_2} &= \frac{V_f}{E_2^f} + \frac{1 - V_f}{E_2^m} \\ &= \frac{0.60}{73.1} + \frac{1 - 0.60}{4.62} \\ &= 0.09478\,\text{GPa}^{-1} \\ E_2 &= \frac{1}{0.09478\,\text{GPa}^{-1}} = 10.55\,\text{GPa} \end{aligned}$$

This value is in relatively poor agreement with the exact value of 15.56 GPa found by using the elasticity solution. For the improved mechanics of materials model, using Eq. (5.6.12),

$$\begin{aligned} \frac{1}{E_2} &= \frac{1 - \sqrt{V_f}}{E_2^m} + \frac{\sqrt{V_f}}{E_2^f\sqrt{V_f} + E_2^m(1 - \sqrt{V_f})} \\ &= \frac{1 - \sqrt{0.60}}{4.62} + \frac{\sqrt{0.60}}{73.1\sqrt{0.60} + 4.62(1 - \sqrt{0.60})} \\ &= 0.0622\,\text{GPa}^{-1} \\ E_2 &= 16.07\,\text{GPa} \end{aligned}$$

α_2 (/°C) $\times 10^6$, Eq. (5.6.16)	41.4	45.0	42.2	38.2	33.8	29.1	24.4	19.62
α_2 (/°C) $\times 10^6$, elasticity	41.4	43.9	40.3	35.8	31.1	26.4	21.8	17.38

This model gives better agreement with the exact value for this case (and others as well) and is the recommended model for E_2. The semiempirical Halpin-Tsai expression, Eq. (5.6.19), with $\xi = 2$ results in

$$E_2 = E_2^m \frac{(E_2^f + \xi E_2^m) - \xi V_f (E_2^m - E_2^f)}{(E_2^f + \xi E_2^m) + V_f (E_2^m - E_2^f)}$$
$$= (4.62) \frac{[73.1 + (2)(4.62)] - (2)(0.60)(4.62 - 73.1)}{[73.1 + (2)(4.62)] + (0.60)(4.62 - 73.1)}$$
$$= 18.42 \text{ GPa}$$

For G_{12}, using Eq. (5.6.13),

$$\frac{1}{G_{12}} = \frac{V_f}{G_{12}^f} + \frac{1 - V_f}{G_{12}^m}$$
$$= \frac{0.60}{30.0} + \frac{1 - 0.60}{1.699}$$
$$= 0.255 \text{ GPa}^{-1}$$
$$G_{12} = 3.91 \text{ GPa}$$

This value compares poorly with the exact value of 5.64 GPa obtained from the elasticity solution. The concentric cylinders approximate elasticity model, Eq. (5.6.14), gives

$$G_{12} = G_{12}^m \frac{(G_{12}^m + G_{12}^f) - V_f (G_{12}^m - G_{12}^f)}{(G_{12}^m + G_{12}^f) + V_f (G_{12}^m - G_{12}^f)}$$
$$= 1.699 \frac{(1.699 + 30.0) - 0.60(1.699 - 30.0)}{(1.699 + 30.0) + 0.60(1.699 - 30.0)}$$
$$= 5.62 \text{ GPa}$$

This model gives good agreement with that of the exact solution, and it is the recommended model for G_{12}.

For α_1, using Eq. (5.6.15),

$$\alpha_1 = \frac{\alpha_1^f E_1^f V_f + \alpha_1^m E_1^m (1 - V_f)}{E_1^f V_f + E_1^m (1 - V_f)}$$
$$= \frac{(5.04 \times 10^{-6})(73.1)(0.60) + (41.4 \times 10^{-6})(4.62)(1 - 0.60)}{73.1(0.60) + 4.62(1 - 0.60)}$$
$$= 6.51 \times 10^{-6}/^\circ\text{C}$$

This value compares favorably with the exact result of $6.72 \times 10^{-6}/^\circ\text{C}$.

For α_2, using Eq. (5.6.16),

$$\alpha_2 = \left[\alpha_2^f - \left(\frac{E_1^m}{E_1}\right)\nu_{12}^f (\alpha_1^m - \alpha_1^f)(1 - V_f)\right] V_f$$
$$+ \left[\alpha_2^m + \left(\frac{E_1^f}{E_1}\right)\nu_{12}^m (\alpha_1^m - \alpha_1^f) V_f\right](1 - V_f)$$
$$= \left[5.04 \times 10^{-6} - \left(\frac{4.62}{45.7}\right)(0.22)(41.4 \times 10^{-6}\right.$$
$$\left. - 5.04 \times 10^{-6})(1 - 0.60)\right](0.60)$$
$$+ \left[41.4 \times 10^{-6} + \left(\frac{73.1}{45.7}\right)(0.36)(41.4 \times 10^{-6}\right.$$
$$\left. - 5.04 \times 10^{-6})(0.60)\right](1 - 0.60)$$
$$= 24.4 \times 10^{-6}/^\circ\text{C}$$

This value compares favorably with the exact result of $21.8 \times 10^{-6}/^\circ\text{C}$.

NOTE: It is important to note that in the above examples and all to follow we assume that the fiber and matrix properties are quantified exactly by using three significant figures, as in Table 5.6.1. All subsequent numerical calculations are carried out by starting with these properties, and these subsequent numerical calculations will be reported rounded to three significant figures. Also note that in all numerical examples to follow, a glass-reinforced composite with 60 percent fiber volume fraction is used. Because of their simplicity and accuracy, the engineering properties are computed by employing Eqs. (5.6.9), (5.6.10), (5.6.12), (5.6.14), (5.6.15), and (5.6.16).

Additional example results may be constructed by examining different fiber volume fraction or changing the fiber type, and comparing the results with the values given in Table 5.6.2 or Table 5.6.3, as appropriate for the fiber type chosen. For the graphite fibers, care must be taken to use the appropriate extensional moduli and expansion coefficients, as these fibers are orthotropic.

Although it has not been necessary to this point to describe the thickness of a layer, in the subsequent numerical examples a layer thickness h of 0.000125 m, or 0.125 mm, will be used.

DESCRIBING A LAMINATE

With details of the properties of a layer considered, we turn our attention to describing the behavior of a number of layers, bonded together, one next to the other, to form a laminate. An important part of the description of a laminate is the specification of its **stacking sequence.** The stacking sequence is a list that defines the through-thickness locations and fiber orientations of all the layers in a laminate. Referring to Fig. 5.6.6, which shows the exploded view of a laminate and the **laminate coordinate system,** the xyz coordinate system, the stacking sequence lists the layer fiber orientations relative to the $+x$ axis of the laminate coordinate system, starting with the layer at the negativemost z position. The stacking sequence $[\pm 30/0]_S$ describes the six-layer laminate shown in Fig. 5.6.6 which has $+30^\circ$ layers on the outside, -30° layers inside of those, and two 0° layers in the center. The stacking sequence could have been written as $[+30/-30/0/0/-30/+30]_T$, where T signifies that the total laminate has been described, but the shorthand notation with the subscript S is more convenient and implies that the fiber orientation arrangement is symmetric with respect to the xy plane, i.e., the $z = 0$ location. The formal definition of a symmetric laminate will be given shortly. Other shorthand notation can be used, such as $[(\pm 30/0)_3/(90/0)_2]_S$ to describe a 26-layer symmetric laminate which has two subsequences that repeat, one 3 times, the other twice. The notation $[\pm 30]_{2S}$ is interpreted to mean $[(\pm 30)_2]_S$. Of course it is necessary to specify the material properties and thickness of each layer to completely describe a laminate.

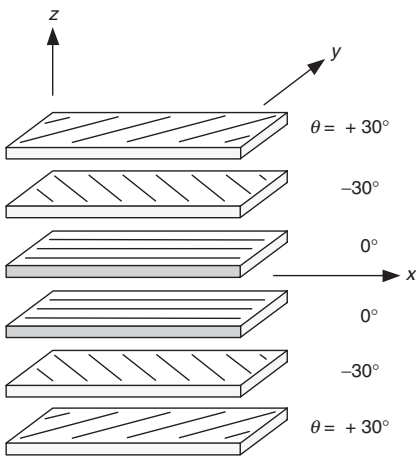

Fig. 5.6.6 Exploded view of a $[\pm 30/0]_S$ laminate and laminate coordinate system.

STRESS-STRAIN BEHAVIOR OF A LAYER: PRINCIPAL MATERIAL COORDINATE SYSTEM

Within the context of the macromechanical theory presented here to study laminate deformations and stresses, referred to as **classical lamination theory,** or **CLT,** a layer is assumed to be in a state of plane stress. Such a condition was previously described. Accordingly, from Eq. (5.6.7), the stress-strain behavior of a layer written in terms of the stresses and strains in the principal material, or 1-2-3, coordinate system, including the effects of thermal expansion, can be written as

$$\begin{Bmatrix} \sigma_1 \\ \sigma_2 \\ \tau_{12} \end{Bmatrix} = \begin{pmatrix} Q_{11} & Q_{12} & 0 \\ Q_{12} & Q_{22} & 0 \\ 0 & 0 & Q_{66} \end{pmatrix} \begin{Bmatrix} \varepsilon_1 - \alpha_1 \Delta T \\ \varepsilon_2 - \alpha_2 \Delta T \\ \gamma_{12} \end{Bmatrix} \tag{5.6.20}$$

where

$$Q_{11} = \frac{E_1}{1 - \nu_{12}\nu_{21}} \qquad Q_{12} = \frac{\nu_{12}E_2}{1 - \nu_{12}\nu_{21}}$$
$$Q_{22} = \frac{E_2}{1 - \nu_{12}\nu_{21}} \qquad Q_{66} = G_{12} \tag{5.6.21}$$

The Q matrix is the **reduced stiffness matrix.** The term *reduced* is used to distinguish the 3-by-3 stiffness matrix of Eq. (5.6.20) from the full 6-by-6 stiffness matrix of Eq. (5.6.4) that must be used when all six components of stress and strain are considered. It is important to recognize that while the numerical values in the reduced compliance matrix are identical to those in the full 6-by-6 compliance matrix, the numerical values in the reduced stiffness matrix are different from those in the full 6-by-6 stiffness matrix. Again, the form of the reduced stiffness matrix in Eq. (5.6.20) is said to represent orthotropic material behavior. For simplicity, moisture content effects have not been included in Eq. (5.6.20). They can be included in the same manner as thermal expansion effects.

EXAMPLE 2. Compute the numerical values of the reduced stiffness matrix for a glass-fiber-reinforced composite.

APPROACH. Substitute the engineering properties directly into Eq. (5.6.21). [As noted, all examples are based on using a 60 percent volume fraction of glass fibers and, because of their simplicity and accuracy, employing Eqs. (5.6.9), (5.6.10), (5.6.12), (5.6.14), (5.6.15), and (5.6.16) to calculate the material properties, as presented in Table 5.6.3.]

SOLUTION

$$Q_{11} = \frac{E_1}{1 - \nu_{12}\nu_{21}} = \frac{45.7 \times 10^9}{1 - (0.276)(0.0970)} = 47.0 \times 10^9 = 47.0\,\text{GPa}$$

$$Q_{12} = \frac{\nu_{12}E_2}{1 - \nu_{12}\nu_{21}} = \frac{0.276(16.07 \times 10^9)}{1 - (0.276)(0.0970)} = 4.56\,\text{GPa}$$

$$Q_{22} = \frac{E_2}{1 - \nu_{12}\nu_{21}} = \frac{16.07 \times 10^9}{1 - (0.276)(0.0970)} = 16.51\,\text{GPa}$$

$$[Q] = \begin{pmatrix} Q_{11} & Q_{12} & 0 \\ Q_{12} & Q_{22} & 0 \\ 0 & 0 & Q_{66} \end{pmatrix} = \begin{pmatrix} 47.0 & 4.56 & 0 \\ 4.56 & 16.51 & 0 \\ 0 & 0 & 5.62 \end{pmatrix} \times 10^9$$
$$= \begin{pmatrix} 47.0 & 4.56 & 0 \\ 4.56 & 16.51 & 0 \\ 0 & 0 & 5.62 \end{pmatrix} \text{GPa}$$

The reciprocity relation of Eq. (5.6.5) was used to compute ν_{21}. We emphasize that in nearly all cases $\nu_{12} \neq \nu_{21}$.

STRESS-STRAIN BEHAVIOR OF A LAYER: LAMINATE COORDINATE SYSTEM

Since there can be many fiber orientations within a laminate, with each orientation having its own principal material coordinate system, it is more convenient to describe laminate behavior in terms of one coordinate system, namely, the laminate, or xyz, coordinate system shown in Fig. 5.6.6. The stresses and strains in the laminate coordinate system, including thermal strains, can be expressed in terms of those in the principal material coordinate system by **transformation relations,** namely,

$$\begin{Bmatrix} \sigma_x \\ \sigma_y \\ \tau_{xy} \end{Bmatrix} = [T]^{-1} \begin{Bmatrix} \sigma_1 \\ \sigma_2 \\ \tau_{12} \end{Bmatrix} \qquad \begin{Bmatrix} \varepsilon_x \\ \varepsilon_y \\ \frac{1}{2}\gamma_{xy} \end{Bmatrix} = [T]^{-1} \begin{Bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \frac{1}{2}\gamma_{12} \end{Bmatrix}$$
$$\begin{Bmatrix} \alpha_x \\ \alpha_y \\ \frac{1}{2}\alpha_{xy} \end{Bmatrix} \Delta T = [T]^{-1} \begin{Bmatrix} \alpha_1 \\ \alpha_2 \\ 0 \end{Bmatrix} \Delta T \tag{5.6.22}$$

where

$$[T]^{-1} = \begin{bmatrix} T_{11} & T_{12} & T_{13} \\ T_{21} & T_{22} & T_{23} \\ T_{31} & T_{32} & T_{33} \end{bmatrix}^{-1} = \begin{bmatrix} m^2 & n^2 & -2mn \\ n^2 & m^2 & 2mn \\ mn & -mn & m^2 - n^2 \end{bmatrix} \tag{5.6.23}$$

and where $m = \cos\theta$ and $n = \sin\theta$, with θ being the angle measured from the $+x$ axis to the $+1$ axis of the layer. In Eq. (5.6.23), the 3-by-3 matrix, denoted as T^1, is referred to as the **inverse transformation matrix.** The word *inverse* is used because the stresses and strains of importance within a laminate are those parallel and perpendicular to the fibers, namely, those in the principal material coordinate system. The principal material coordinate system stresses and strains are used to determine at what load level a layer will fail. The relationship in Eq. (5.6.22) transforms those important stresses and strains into stresses and strains in the xyz coordinate system. The latter quantities are neither parallel nor perpendicular to the fibers, so it is more difficult to evaluate whether the stresses and strains are high enough to cause, e.g., failure of a layer due to excess stress in the fiber direction. Note well in the above relations to factor of ½ associated with the sheer strain.

The above relations can be inverted and rewritten as

$$\begin{Bmatrix} \sigma_1 \\ \sigma_2 \\ \tau_{12} \end{Bmatrix} = [T] \begin{Bmatrix} \sigma_x \\ \sigma_y \\ \tau_{xy} \end{Bmatrix} \qquad \begin{Bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \frac{1}{2}\gamma_{12} \end{Bmatrix} = [T] \begin{Bmatrix} \varepsilon_x \\ \varepsilon_y \\ \frac{1}{2}\gamma_{xy} \end{Bmatrix}$$
$$\begin{Bmatrix} \alpha_1 \\ \alpha_2 \\ 0 \end{Bmatrix} \Delta T = [T] \begin{Bmatrix} \alpha_x \\ \alpha_y \\ \frac{1}{2}\alpha_{xy} \end{Bmatrix} \Delta T \tag{5.6.24}$$

where

$$[T] = \begin{bmatrix} T_{11} & T_{12} & T_{13} \\ T_{21} & T_{22} & T_{23} \\ T_{31} & T_{32} & T_{33} \end{bmatrix} = \begin{bmatrix} m^2 & n^2 & 2mn \\ n^2 & m^2 & -2mn \\ -mn & mn & m^2 - n^2 \end{bmatrix} \tag{5.6.25}$$

The above 3-by-3 matrix, denoted as T, is referred to as the **transformation matrix.**

As a result of the fibers being at an angle relative to the laminate coordinate system, stresses and strains measured in the laminate coordinate system are quite different from those measured in the principal material coordinate system. Example 3 demonstrates the interesting strain response of a single layer caused by a temperature change, but measured in the laminate coordinate system.

EXAMPLE 3. The temperature of an element cut from a single layer of glass epoxy with its fibers at $+30°$ is decreased by $-100\,°\text{C}$. What shear strain is measured in the laminate coordinate system due to this temperature decrease? Note that this temperature decrease is similar in magnitude to the decrease from the curing temperature of the material to room temperature.

APPROACH. The thermally induced strains in the laminate coordinate system can be computed from the known values of the thermally induced strains in the principal material coordinate system from Table 5.6.3 and the transformation relations of Eqs. (5.6.22) and (5.6.23).

SOLUTION. Since $\theta = 30°$, $m = \sqrt{3}/2$, and $n = 1/2$,

$$\begin{Bmatrix} \alpha_x \\ \alpha_y \\ \frac{1}{2}\alpha_{xy} \end{Bmatrix} \Delta T = [T(30°)]^{-1} \begin{Bmatrix} \alpha_1 \\ \alpha_2 \\ 0 \end{Bmatrix} \Delta T$$
$$= \begin{bmatrix} \frac{3}{4} & \frac{1}{4} & \frac{-\sqrt{3}}{2} \\ \frac{1}{4} & \frac{3}{4} & \frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{4} & \frac{-\sqrt{3}}{4} & \frac{1}{2} \end{bmatrix} \begin{Bmatrix} 6.51 \times 10^{-6} \\ 24.4 \times 10^{-6} \\ 0 \end{Bmatrix} (-100)$$

or

$$\alpha_x \Delta T = -1{,}099 \times 10^{-6} \qquad \alpha_y \Delta T = -1{,}099 \times 10^{-6}$$
$$\alpha_{xy} \Delta T = 1{,}551 \times 10^{-6}$$

DISCUSSION. What is important to note is that although there is no shear strain in the principal material coordinate system, i.e., $\alpha_{12}\,\Delta T = 0$, a shear strain as well as contraction strains in the x and y directions are measured in the laminate coordinate system. Since polymer matrix composites are cured at an elevated temperature and then cooled, when a layer is part of a laminate, the thermally induced strains in a layer caused by cooling the laminate from its curing temperature can produce residual thermal stresses. If the element is square and 0.1 m × 0.1 m in dimensions before the temperature change, after cooling the length in the x and y directions would be less. In addition, the original right angles would be changed by 1,551 microradians, denoted as 1,551 μrad, or 0.0888 deg, as shown in exaggerated fashion in Fig. 5.6.7, with the right angles of two opposite corners increasing and the right angles of the other two opposite corners decreasing. This may not seem like much of an angle change, but it can cause significant stresses if resisted. The strains in the x and y directions are –1,099 and –1,994 microstrain, denoted, respectively, as –1,099 and –1,994 $\mu\varepsilon$. The deformed element would have dimensions 0.0999 and 0.0998 m in the x and y directions, respectively.

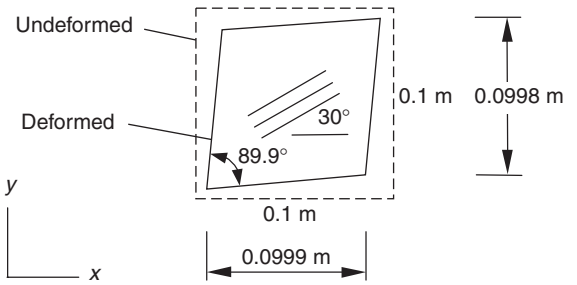

Fig. 5.6.7 Cooling deformations of an element with fibers as oriented at + 30°.

As it is convenient to transform the stresses and strains from each of the principal material coordinate systems of the various layers to the single laminate coordinate system, it is convenient to transform the stress-strain relation of each layer to the laminate coordinate system. This can be accomplished by starting with the stress-strain relation of Eq. (5.6.20) and applying the transformation relations of Eq. (5.6.22). As a result, the stress-strain relation expressed in the laminate coordinate system is written as

$$\begin{Bmatrix}\sigma_x\\ \sigma_y\\ \tau_{xy}\end{Bmatrix} = \begin{pmatrix}\overline{Q}_{11} & \overline{Q}_{12} & \overline{Q}_{16}\\ \overline{Q}_{12} & \overline{Q}_{22} & \overline{Q}_{26}\\ \overline{Q}_{16} & \overline{Q}_{26} & \overline{Q}_{66}\end{pmatrix}\begin{Bmatrix}\varepsilon_x - \alpha_x\,\Delta T\\ \varepsilon_y - \alpha_x\,\Delta T\\ \gamma_{xy} - \alpha_{xy}\,\Delta T\end{Bmatrix} \qquad (5.6.26)$$

where

$$\begin{aligned}
\overline{Q}_{11} &= Q_{11}m^4 + 2(Q_{12} + 2Q_{66})m^2n^2 + Q_{22}n^4\\
\overline{Q}_{12} &= (Q_{11} + Q_{22} - 4Q_{66})n^2m^2 + Q_{12}(n^4 + m^4)\\
\overline{Q}_{16} &= (Q_{11} - Q_{12} - 2Q_{66})nm^3 + (Q_{12} - Q_{22} + 2Q_{66})n^3m\\
\overline{Q}_{22} &= Q_{11}n^4 + 2(Q_{12} + 2Q_{66})m^2n^2 + Q_{22}m^4\\
\overline{Q}_{26} &= (Q_{11} - Q_{12} - 2Q_{66})n^3m + (Q_{12} - Q_{22} + 2Q_{66})nm^3\\
\overline{Q}_{66} &= (Q_{11} + Q_{22} - 2Q_{12} - 2Q_{66})n^2m^2 + Q_{66}(n^4 + m^4)
\end{aligned} \qquad (5.6.27)$$

As mentioned, $m = \cos\theta$ and $n = \sin\theta$, so the $\overline{Q}$ terms are functions of θ. The 3-by-3 $\overline{Q}$ matrix is referred to as the **transformed reduced stiffness matrix.** As can be observed, because of fiber orientation, compared to conventional isotropic materials or the orthotropic behavior of Eq. (5.6.20), unusual relations between stresses and strains occur. Specifically, the shear stress is related to the two normal strains, and the two normal stresses are related to the shear strain. There are no zeros in the $\overline{Q}$ matrix as there are with the Q matrix in Eq. (5.6.20). The behavior represented by Eq. (5.6.27) is referred to as **anisotropic behavior.** A word of caution: Note carefully the factors of ½ and 2 that occur in some relations but not in others. This is due to the use of engineering shear strains γ_{12} and γ_{xy}, as opposed to tensor shear strains, which are given by $\frac{1}{2}\gamma_{12}$ and $\frac{1}{2}\gamma_{xy}$.

EXAMPLE 4. A normal stress of 50 MPa is applied in the x direction to a square element of composite material with its fibers at 30° relative to the + x axis while the temperature is kept constant, i.e., $\Delta T = 0$. No other stresses are present. What strains result from this applied stress?

APPROACH AND SOLUTION. Substituting directly into the stress-strain relation expressed in the laminate coordinate system, Eq. (5.6.26), gives

$$\begin{Bmatrix}\sigma_x\\ \sigma_y\\ \tau_{xy}\end{Bmatrix} = \begin{Bmatrix}50 \times 10^6\\ 0\\ 0\end{Bmatrix} = \begin{pmatrix}\overline{Q}_{11}(30°) & \overline{Q}_{12}(30°) & \overline{Q}_{16}(30°)\\ \overline{Q}_{12}(30°) & \overline{Q}_{22}(30°) & \overline{Q}_{26}(30°)\\ \overline{Q}_{16}(30°) & \overline{Q}_{26}(30°) & \overline{Q}_{66}(30°)\end{pmatrix}\begin{Bmatrix}\varepsilon_x\\ \varepsilon_y\\ \gamma_{xy}\end{Bmatrix}$$

where the $\overline{Q}'s$ are computed by using Eq. (5.6.27) with $\theta = 30°$, namely,

$$\begin{pmatrix}\overline{Q}_{11}(30°) & \overline{Q}_{12}(30°) & \overline{Q}_{16}(30°)\\ \overline{Q}_{12}(30°) & \overline{Q}_{22}(30°) & \overline{Q}_{26}(30°)\\ \overline{Q}_{16}(30°) & \overline{Q}_{26}(30°) & \overline{Q}_{66}(30°)\end{pmatrix} = \begin{pmatrix}33.4 & 10.54 & 10.05\\ 10.54 & 18.15 & 3.14\\ 10.05 & 3.14 & 11.60\end{pmatrix} \times 10^9\ \text{N/m}^2$$

resulting in

$$\begin{pmatrix}33.4 & 10.54 & 10.05\\ 10.54 & 18.15 & 3.14\\ 10.05 & 3.14 & 11.60\end{pmatrix} \times 10^9 \begin{Bmatrix}\varepsilon_x\\ \varepsilon_y\\ \gamma_{xy}\end{Bmatrix} = \begin{Bmatrix}50 \times 10^6\\ 0\\ 0\end{Bmatrix}$$

which leads to

$$\begin{Bmatrix}\varepsilon_x\\ \varepsilon_y\\ \gamma_{xy}\end{Bmatrix} = \begin{Bmatrix}2{,}370\\ -1{,}069\\ -1{,}760\end{Bmatrix} \times 10^{-6}$$

As shown in Fig. 5.6.8, the element of material stretches in the x direction and contracts in the y direction, as an element of conventional material such as aluminum or steel would, the contraction being due to Poisson effects. Unlike an element of conventional material, however, the element experiences a shear strain. This results in corner angles that are not right angles when the square element deforms.

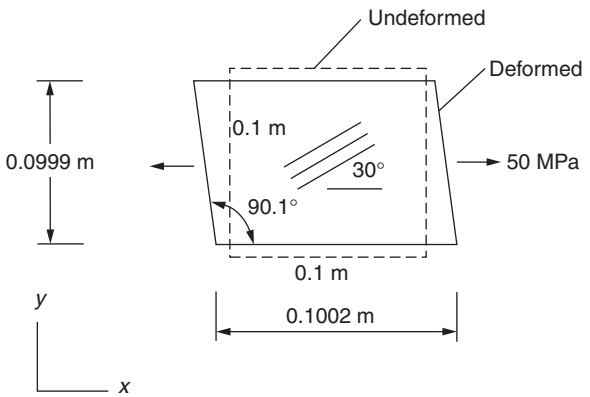

Fig. 5.6.8 Deformations due to application of 50-MPa normal stress in x direction.

To be noted is the fact that there is distinct difference between stating that the element of material is *stressed* in the x direction and stating that the element of material is *strained* in the x direction. If the element is strained in the x direction by, e.g., 1,000 $\mu\varepsilon$, with the element experiencing no other strains, then the stresses required are given by again using Eq. (5.6.26), namely,

$$\begin{Bmatrix}\sigma_x\\ \sigma_y\\ \tau_{xy}\end{Bmatrix} = \begin{pmatrix}\overline{Q}_{11}(30°) & \overline{Q}_{12}(30°) & \overline{Q}_{16}(30°)\\ \overline{Q}_{12}(30°) & \overline{Q}_{22}(30°) & \overline{Q}_{26}(30°)\\ \overline{Q}_{16}(30°) & \overline{Q}_{26}(30°) & \overline{Q}_{66}(30°)\end{pmatrix}\begin{Bmatrix}1{,}000\\ 0\\ 0\end{Bmatrix} \times 10^{-6}$$

or $$\begin{Bmatrix}\sigma_x\\ \sigma_y\\ \tau_{xy}\end{Bmatrix} = \begin{Bmatrix}33.4\\ 10.54\\ 10.05\end{Bmatrix} \times 10^6\ \text{Pa} = \begin{Bmatrix}33.4\\ 10.54\\ 10.05\end{Bmatrix}\text{MPa}$$

It can be concluded that to produce this rather simple state of deformation, a tensile stress in the y direction and a positive shear stress, in addition to a tensile

stress in the x direction, are required. These stresses are illustrated in Fig. 5.6.9. For a conventional material, although a tensile stress in the y direction would be required, the shear stress would not be required because there is no tendency for the corner right angle to change. If the fiber angle were $-30°$, the same tensile stresses in the x and y directions would be required, but the shear stress required would be –10.05 MPa, a negative shear stress.

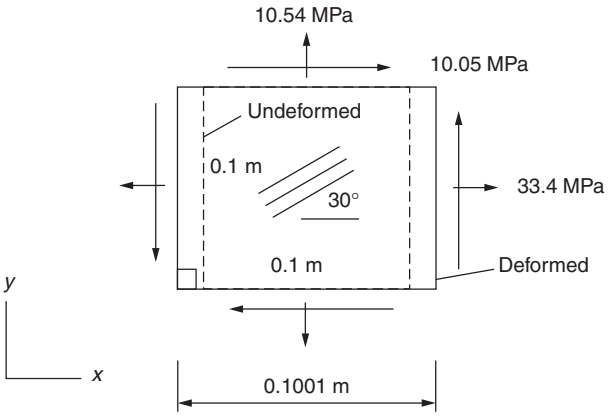

Fig. 5.6.9 Stresses required to produce strain of 1,000 $\mu\varepsilon$ in the x direction.

MACROMECHANICS OF A LAMINATE

When layers are combined to form a laminate, the unusual behavior in the various layers can interact to produce results that are even more unusual than the behavior of a single layer. To study the behavior of a laminate, it is assumed that within a laminate the layers are perfectly bonded together and do not slip relative to one another. Only small deformations are considered, much the same as in studying the mechanics of conventional materials. Like a layer, a laminate occupies a volume in three-dimensional space, so the analysis and the design of laminates are truly a three-dimensional problem. However, the plane stress assumption eliminates some of the three-dimensionality of the problem, as does one other key assumption, namely, the **Kirchhoff hypothesis.** As a direct result of the Kirchhoff hypothesis, the strains $\varepsilon_x, \varepsilon_y$, and γ_{xy} vary linearly through the thickness of the laminate. If the no-slip condition were not true, the Kirchhoff hypothesis certainly would not be valid. The Kirchhoff hypothesis assumes that when the laminate deflects out of plane in the z direction, all points through the thickness of the laminate at a given x and y location deflect out of plane the same amount. That is, the out-of-plane displacement of a point within a laminate is independent of the z location of the point. The assumed deformation characteristics of a laminate are further illustrated in Fig. 5.6.10, where the deformation is viewed in the xz plane. The figure shows that straight line AA' through the thickness of the laminate before deformation remains straight after deformation, a result that leads to a linear variation of strains through the thickness of the laminate. Specifically, the displacements in the x, y, and z directions of a generic point P at location x, y, z within the laminate are assumed to have the following forms:

$$\begin{aligned} u(x,y,z) &= u^o(x,y) - z\frac{\partial w^o(x,y)}{\partial x} \\ v(x,y,z) &= v^o(x,y) - z\frac{\partial w^o(x,y)}{\partial y} \\ w(x,y,z) &= w^o(x,y) \end{aligned} \tag{5.6.28}$$

where the superscript o denotes the displacements of corresponding point P^o on the **geometric midplane** of the laminate, which is also referred to as the **reference surface.** Only small displacements and rotations are considered in the development of Eq. (5.6.28). As will be seen, if the deformation of the reference surface is known, i.e., if the strains and curvatures of the reference surface are known, then the strains, and subsequently the stresses, in every layer can be determined. The reference surface is somewhat like the neutral axis in simple beam analysis, except with composite materials the stresses are not necessarily zero at the reference surface location.

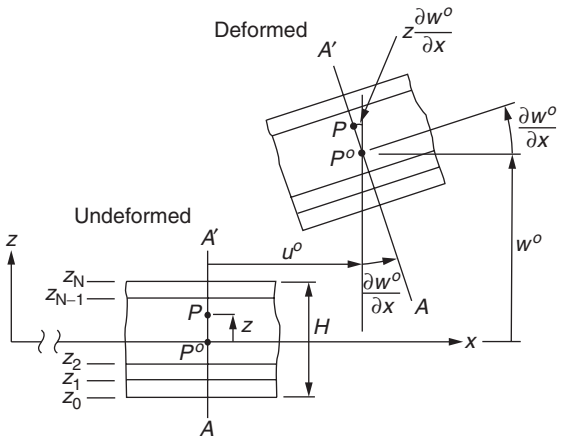

Fig. 5.6.10 Implications of Kirchhoff hypothesis for laminate deformations.

To be noted in Fig. 5.6.10 is the notation z_0, z_1, z_2, . . . which describes the z locations of the interfaces between layers, or alternatively, the z locations of the lower and upper surfaces of the layers. Accordingly, $z_0 = -H/2$, with H being the total laminate thickness, and the thickness of the kth layer h_k is given by $z_k - z_{z-1}$.

The strains at any location within the laminate can be written in terms of the displacements as

$$\begin{aligned} \varepsilon_x &= \frac{\partial u}{\partial x} = \frac{\partial u^o}{\partial x} - z\frac{\partial^2 w^o}{\partial x^2} = \varepsilon_x^o + z\kappa_x^o \\ \varepsilon_y &= \frac{\partial v}{\partial y} = \frac{\partial v^o}{\partial y} - z\frac{\partial^2 w^o}{\partial y^2} = \varepsilon_y^o + z\kappa_y^o \\ \gamma_{xy} &= \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} = \frac{\partial u^o}{\partial y} + \frac{\partial v^o}{\partial x} - 2z\frac{\partial^2 w^o}{\partial x\,\partial y} = \gamma_{xy}^o + z\kappa_{xy}^o \end{aligned} \tag{5.6.29}$$

where

$$\begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_y^0 \\ \gamma_{xy}^o \end{Bmatrix} = \begin{Bmatrix} \dfrac{\partial u^o}{\partial x} \\ \dfrac{\partial v^o}{\partial y} \\ \dfrac{\partial u^o}{\partial y} + \dfrac{\partial v^o}{\partial x} \end{Bmatrix} \qquad \begin{Bmatrix} \kappa_x^o \\ \kappa_y^o \\ \kappa_{xy}^o \end{Bmatrix} = \begin{Bmatrix} -\dfrac{\partial^2 w^o}{\partial x^2} \\ -\dfrac{\partial^2 w^o}{\partial y^2} \\ -2\dfrac{\partial^2 w^o}{\partial x\,\partial y} \end{Bmatrix} \tag{5.6.30}$$

The quantities ε_x^o, ε_y^o, and γ_{xy}^o are referred to as the **midplane** or **reference surface strains.** The quantities κ_x^o, κ_y^o, and κ_{xy}^o are the **midplane** or **reference surface curvatures** and are the bending curvatures of the x and y directions, and the twist curvature, respectively, of the reference surface. By knowing the midplane strains and curvatures, the state of strain at any z location within any layer can be computed though the use of Eq. (5.6.29). These strains, in turn, can be transformed to determine the strains in the principal material coordinate system of the layer at this z location by using the second equation of Eq. (5.6.24). The stresses in the laminate coordinate system at this z location can then be computed using Eq. (5.6.20). As can be seen, then, knowing the midplane strains and curvatures is key to determining the stresses anywhere through the thickness of the laminate. The plane stress assumption and the Kirchhoff hypothesis are keys to the analysis simplifying to this

degree. Without these assumptions, the design and analysis of composite laminates would be intractable.

Since the midplane strains and curvatures are the keys to determining the stresses within a laminate, it is important to be able to compute these midplane quantities in terms of the loads applied to a laminate. In the application of composite materials, most often loads, in the form of pressures, forces, or bending moments, are specified rather than midplane strains and curvatures, or rather than the stresses. A relationship between the specified loads and the midplane strains and curvatures is therefore necessary. So far all that has been discussed are strains and stresses. Therefore, relationships between *loads* and the stresses or between *loads* and the midplane strains and curvatures need to be developed to be able to proceed with studying the behavior of laminates in practical applications. To develop these relations, the loads are defined in terms of the stresses as follows:

$$N_x = \int_{-H/2}^{H/2} \sigma_x \, dz \qquad N_y = \int_{-H/2}^{H/2} \sigma_y \, dz \qquad N_{xy} = \int_{-H/2}^{H/2} \tau_{xy} \, dz$$
$$M_x = \int_{-H/2}^{H/2} \sigma_x z \, dz \qquad M_y = \int_{-H/2}^{H/2} \sigma_y z \, dz \qquad M_{xy} = \int_{-H/2}^{H/2} \tau_{xy} z \, dz \tag{5.6.31}$$

The Ns are the *force resultants* and the Ms are the *moment resultants*. The units of the force and moment resultants are force *per unit length* and moment *per unit length*, respectively. Collectively the six quantities are the *stress resultants*. The introduction of the stress resultants further reduces the three-dimensional nature of the problem. The *per unit length* part of the definition of the stress resultants is very important. The resultant N_x is the force in the x direction per unit length of the laminate in the y direction; N_y is the force in the y direction per unit length of laminate in the x direction. Similar interpretations are associated with the moment resultants M_x and M_y. Since it is based on stress component τ_{xy}, the force resultant N_{xy} is the force in the x direction per unit length of laminate in the y direction. However, it is also the force in the y direction per unit length of laminate in the x direction, depending on which edge of the laminate is being discussed. A similar dual definition is associated with M_{xy}. It should be emphasized that it is impossible from equilibrium considerations to have N_{xy} and M_{xy} acting on one edge of an element of material and not have the same values of N_{xy} and M_{xy} acting on the adjacent edge. It is important to be aware of the positive sense of the stress resultants, which are illustrated in Fig. 5.6.11.

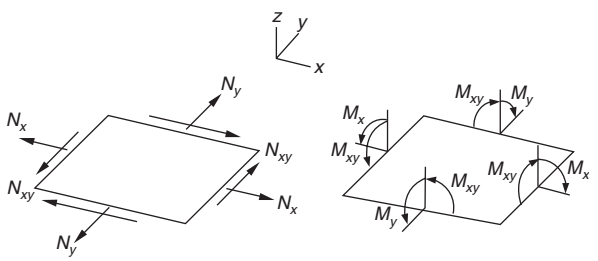

Fig. 5.6.11 Illustration of positive sense of force and moment resultants.

If the three components of stress from Eq. (5.6.26) are substituted into the integrands of the definitions of the six stress resultants, the integration with respect to z can be carried out. Considering N_x as an example, substitution of the first equation of the stress-strain relation from Eqs. (5.6.26) into the first equation of Eqs. (5.6.31) results in

$$N_x = \int_{-H/2}^{H/2} [\overline{Q}_{11}(\varepsilon_x^o + z\kappa_x^o - \alpha_x \Delta T) + \overline{Q}_{12}(\varepsilon_y^o + z\kappa_y^o - \alpha_y \Delta T) + \overline{Q}_{16}(\gamma_{xy}^o + z\kappa_{xy}^o - \alpha_{xy} \Delta T)] \, dz \tag{5.6.32}$$

Regrouping gives

$$N_x = \int_{-H/2}^{H/2} [\overline{Q}_{11}(\varepsilon_x^o + z\kappa_x^o) + \overline{Q}_{12}(\varepsilon_y^o + z\kappa_y^o) + \overline{Q}_{16}(\gamma_{xy}^o + z\kappa_{xy}^o)] \, dz - \int_{-H/2}^{H/2} (\overline{Q}_{11}\alpha_x + \overline{Q}_{12}\alpha_y + \overline{Q}_{16}\alpha_{xy}) \Delta T \, dz \tag{5.6.33}$$

The second integral is special. It is defined as the **effective thermal force resultant in** the x direction, i.e.,

$$N_x^T = \int_{-H/2}^{H/2} (\overline{Q}_{11}\alpha_x + \overline{Q}_{12}\alpha_y + \overline{Q}_{16}\alpha_{xy}) \Delta T \, dz \tag{5.6.34}$$

where the superscript T identifies that the resultant is due to thermal effects. If the temperature change is not a function of z, i.e., if the temperature change is uniform through the thickness of the laminate, then ΔT can be removed from the integral to yield

$$N_x^T = \left[\int_{-H/2}^{H/2} (\overline{Q}_{11}\alpha_x + \overline{Q}_{12}\alpha_y + \overline{Q}_{16}\alpha_{xy}) \, dz \right] \Delta T \tag{5.6.35}$$

The integral within the brackets is called the *unit effective thermal force resultant*. It is only a function of material properties and the laminate geometry and is defined as

$$\hat{N}_x^T = \int_{-H/2}^{H/2} (\overline{Q}_{11}\alpha_x + \overline{Q}_{12}\alpha_y + \overline{Q}_{16}\alpha_{xy}) \, dz \tag{5.6.36}$$

Note that in the definition of the unit effective thermal force resultant, the coefficients of thermal expansion combine with the reduced stiffnesses. This indicates that the magnitude of the thermal effects depends not only on the thermal expansion or contraction of the individual layers due to temperature changes, but also on how resistant the layers are to deformation, i.e., how stiff they are. By using the nomenclature of Eq. (5.6.36), Eq. (5.6.33) can be written as

$$N_x = \left(\int_{-H/2}^{H/2} \overline{Q}_{11} \, dz \right) \varepsilon_x^o + \left(\int_{-H/2}^{H/2} \overline{Q}_{12} \, dz \right) \varepsilon_y^o + \left(\int_{-H/2}^{H/2} \overline{Q}_{16} \, dz \right) y_{xy}^o + \left(\int_{-H/2}^{H/2} (\overline{Q}_{11} z \, dz \right) \kappa_x^o + \left(\int_{-H/2}^{H/2} (\overline{Q}_{12} z \, dz \right) \kappa_y^o + \left(\int_{-H/2}^{H/2} \overline{Q}_{16} z \, dz \right) \kappa_{xy}^o - \hat{N}_x^T \Delta T \tag{5.6.37}$$

where the reference surface strains and curvatures have been removed from the integral because they are not functions of z and are therefore not involved in the integration with respect to z. This is a very important point, and it is a direct result of the Kirchhoff hypothesis. As a final step, Eq. (5.6.37) is written as

$$N_x = A_{11}\varepsilon_x^o + A_{12}\varepsilon_y^o + A_{16}y_{xy}^o + B_{11}\kappa_x^o + B_{12}\kappa_y^o + B_{16}\kappa_{xy}^o - \hat{N}_x^T \Delta T \tag{5.6.38}$$

The As and Bs are defined as the integrals of the reduced stiffnesses through the thickness of the laminate, and hence they represent **smeared, integrated,** or **overall stiffnesses** of the laminate. The reduced stiffnesses of every layer contribute to the smeared stiffnesses of the laminate. In the same spirit, the effective thermal force resultant represents smeared, integrated, or overall effects. Note that Eq. (5.6.38) relates the three reference surface strains and three reference surface curvatures to the force resultant and to thermal effects. This relationship and the other five to follow are quite important and absolutely necessary if the stresses within the various layers are to be computed from the loads. Before proceeding, it should be noted, as was stated at the onset,

that smearing of properties is used for a second time with the definition of the *A*s, *B*s, and the effective thermal force resultant. The smearing of properties, be it at the micromechanics level or at the macromechanics, or laminate, level, is essential if progress is to be made in modeling and predicting behavior.

If the other five integrals in Eq. (5.6.31) are treated in a similar fashion and the results combined with Eq. (5.6.38), the following relationship results:

$$\begin{Bmatrix} N_x \\ N_y \\ N_{xy} \\ M_x \\ M_y \\ M_{xy} \end{Bmatrix} = \begin{bmatrix} A_{11} & A_{12} & A_{16} & B_{11} & B_{12} & B_{16} \\ A_{12} & A_{22} & A_{26} & B_{12} & B_{22} & B_{26} \\ A_{16} & A_{26} & A_{66} & B_{16} & B_{26} & B_{66} \\ B_{11} & B_{12} & B_{16} & D_{11} & D_{12} & D_{16} \\ B_{12} & B_{22} & B_{26} & D_{12} & D_{22} & D_{26} \\ B_{16} & B_{26} & B_{66} & D_{16} & D_{26} & D_{66} \end{bmatrix} \begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_y^o \\ \gamma_{xy}^o \\ \kappa_x^o \\ \kappa_y^o \\ \kappa_{xy}^o \end{Bmatrix} - \begin{Bmatrix} \hat{N}_x^T \\ \hat{N}_y^T \\ \hat{N}_{xy}^T \\ \hat{M}_x^T \\ \hat{M}_y^T \\ \hat{M}_{xy}^T \end{Bmatrix} \Delta T \tag{5.6.39}$$

The 6-by-6 matrix is referred to as the **laminate stiffness matrix** or, more simply, the *ABD matrix*. This matrix relates the stress resultants, or loads, to the deformations, or strains and curvatures, of the reference surface. Since the reduced stiffnesses do not vary through the thickness of any particular layer, the integrals that define the elements of the *ABD* matrix reduce to summations, namely,

$$A_{ij} = \sum_{k=1}^{N} \overline{Q}_{ij_k}(z_k - z_{k-1}) \qquad B_{ij} = \frac{1}{2}\sum_{k=1}^{N} \overline{Q}_{ij_k}(z_k^2 - z_{k-1}^2)$$
$$D_{ij} = \frac{1}{3}\sum_{k=1}^{N} \overline{Q}_{ij_k}(z_k^3 - z_{k-1}^3) \tag{5.6.40}$$

where the z_k are defined in Fig. 5.6.10 and N is the number of layers in the laminate. Since the coefficients of thermal expansion also do not vary through the thickness of any particular layer, the unit effective thermal stress resultants become summations given by

$$\begin{aligned}
\hat{N}_x^T &= \sum_{k=1}^{N} (\overline{Q}_{11k}\alpha_{xk} + \overline{Q}_{12k}\alpha_{yk} + \overline{Q}_{16k}\alpha_{xyk})(z_k - z_{k-1}) \\
\hat{N}_y^T &= \sum_{k=1}^{N} (\overline{Q}_{12k}\alpha_{xk} + \overline{Q}_{22k}\alpha_{yk} + \overline{Q}_{26k}\alpha_{xyk})(z_k - z_{k-1}) \\
\hat{N}_{xy}^T &= \sum_{k=1}^{N} (\overline{Q}_{16k}\alpha_{xk} + \overline{Q}_{26k}\alpha_{yk} + \overline{Q}_{66k}\alpha_{xyk})(z_k - z_{k-1}) \\
\hat{M}_x^T &= \frac{1}{2}\sum_{k=1}^{N} (\overline{Q}_{11k}\alpha_{xk} + \overline{Q}_{12k}\alpha_{yk} + \overline{Q}_{16k}\alpha_{xyk})(z_k^2 - z_{k-1}^2) \\
\hat{M}_y^T &= \frac{1}{2}\sum_{k=1}^{N} (\overline{Q}_{12k}\alpha_{xk} + \overline{Q}_{22k}\alpha_{yk} + \overline{Q}_{26k}\alpha_{xyk})(z_k^2 - z_{k-1}^2) \\
\hat{M}_{xy}^T &= \frac{1}{2}\sum_{k=1}^{N} (\overline{Q}_{16k}\alpha_{xk} + \overline{Q}_{26k}\alpha_{yk} + \overline{Q}_{66k}\alpha_{xyk})(z_k^2 - z_{k-1}^2)
\end{aligned} \tag{5.6.41}$$

An inspection of the various elements of the *ABD* matrix reveals that not only do their definitions depend on the reduced stiffnesses of every layer, but also their definitions include the location within the laminate of every layer by virtue of z_k and z_{k-1}. The elements of the *ABD* matrix are thus weighted and smeared stiffness quantities, the weighting factor being the thickness and location of the various layers within the laminate. Strictly speaking, the values of the *A*s involve only the layer thicknesses, i.e., $z_k - z_{k-1} = h_k$, the thickness of the kth layer, while the values of the *B*s and *D*s involve layer thicknesses and locations. Physically, the *A*s are the in-plane stiffnesses of the laminate, the *D*s are the bending stiffnesses, and the *B*s are unique to composite materials and are referred to as the *bending-stretching stiffnesses*. This nomenclature refers to the fact that through these terms, bending effects, namely, the curvatures, κ_x^o, κ_y^o, and κ_{xy}^o, are coupled to in-plane force resultants N_x, N_y, and N_{xy}, and conversely, the in-plane strains ε_x^o, ε_y^o, and γ_{xy}^o are coupled to the bending moment resultants M_x, M_y, and M_{xy}. The unit effective thermal stress resultants are also functions of stiffnesses and coefficients of thermal expansion weighted by geometry. With the elements of the *ABD* matrix and the unit effective thermal stress resultants depending on layer thickness and location, a layer can have greater or less influence on the overall behavior of a laminate, depending on its location within the stacking sequence and its thickness. It is important to realize that once the location, material properties, and fiber orientation of each layer are known, the sums defining the *ABD* matrix and the unit effective thermal stress resultants can be computed and numerical values obtained.

Special Cases of Laminate Stacking Sequences

For so-called **symmetric laminates**, all elements of the *B* matrix are 0, as are the three unit effective thermal moment resultants if the temperature change ΔT is uniform through the thickness of the laminate. A symmetric laminate is defined as follows: If, for every layer at a specific location and with a specific thickness, material properties, and fiber orientation located on one side of the geometric midplane, there is a layer with identical thickness, material properties, and fiber orientation at the mirror-image location on the other side of the geometric midplane, then the laminate is said to be symmetric. For **balanced laminates**, A_{16}, A_{26}, and $\hat{N}_{xy}^T$ are zero. A balanced laminate is defined as follows: If, for every layer with a specific thickness, material properties, and fiber orientation, there is a layer *somewhere* within the laminate with the same specific thickness and material properties, but with the *opposite* fiber orientation, then the laminate is said to be balanced. Symmetric and balanced laminates are very common, and the relation of Eq. (5.6.39) simplifies considerably to

$$\begin{Bmatrix} N_x \\ N_y \\ N_{xy} \\ M_x \\ M_y \\ M_{xy} \end{Bmatrix} = \begin{bmatrix} A_{11} & A_{12} & 0 & 0 & 0 & 0 \\ A_{12} & A_{22} & 0 & 0 & 0 & 0 \\ 0 & 0 & A_{66} & 0 & 0 & 0 \\ 0 & 0 & 0 & D_{11} & D_{12} & D_{16} \\ 0 & 0 & 0 & D_{12} & D_{22} & D_{26} \\ 0 & 0 & 0 & D_{16} & D_{26} & D_{66} \end{bmatrix} \begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_y^o \\ \gamma_{xy}^o \\ \kappa_x^o \\ \kappa_y^o \\ \kappa_{xy}^o \end{Bmatrix} - \begin{Bmatrix} \hat{N}_x^T \\ \hat{N}_y^T \\ 0 \\ 0 \\ 0 \\ 0 \end{Bmatrix} \Delta T \tag{5.6.42}$$

It is important to note that D_{16} and D_{26} are not zero. It is also important to remember that if the temperature is not uniform through the thickness of the laminate, even though the laminate is symmetric, Eq. (5.6.42) does not apply. Because of the simplifications, Eq. (5.6.42) can be written as two separate equations, namely,

$$\begin{Bmatrix} N_x \\ N_y \\ N_{xy} \end{Bmatrix} = \begin{Bmatrix} A_{11} & A_{12} & 0 \\ A_{12} & A_{22} & 0 \\ 0 & 0 & A_{66} \end{Bmatrix} \begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_y^o \\ \gamma_{xy}^o \end{Bmatrix} - \begin{Bmatrix} \hat{N}_x^T \\ \hat{N}_y^T \\ 0 \end{Bmatrix} \Delta T$$
$$= [A] \begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_y^o \\ \gamma_{xy}^o \end{Bmatrix} - \begin{Bmatrix} \hat{N}_x^T \\ \hat{N}_y^T \\ 0 \end{Bmatrix} \Delta T \tag{5.6.43}$$

$$\begin{Bmatrix} M_x \\ M_y \\ M_{xy} \end{Bmatrix} = \begin{Bmatrix} D_{11} & D_{12} & D_{16} \\ D_{12} & D_{22} & D_{26} \\ D_{16} & D_{26} & D_{66} \end{Bmatrix} \begin{Bmatrix} \kappa_x^o \\ \kappa_y^o \\ \kappa_{xy}^o \end{Bmatrix} = [D] \begin{Bmatrix} \kappa_x^o \\ \kappa_y^o \\ \kappa_{xy}^o \end{Bmatrix} \tag{5.6.44}$$

where it is seen that for symmetric laminates, bending effects (M_x, M_y, M_{xy} and κ_x^o, κ_y^o, κ_{xy}^o) and in-plane effects (N_x, N_y, N_{xy} and ε_x^o, ε_y^o, γ_{xy}^o) decouple. Actually, Eq. (5.6.43) can be further simplified to two other equations as

$$\begin{Bmatrix} N_x \\ N_y \end{Bmatrix} = \begin{bmatrix} A_{11} & A_{12} \\ A_{12} & A_{22} \end{bmatrix} \begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_y^o \end{Bmatrix} - \begin{Bmatrix} \hat{N}_x^T \\ \hat{N}_y^T \end{Bmatrix} \Delta T \tag{5.6.45}$$

$$N_{xy} = A_{66}\gamma_{xy}^o \tag{5.6.46}$$

Cross-ply laminates are laminates constructed of layers with fiber orientations of only 0 or 90°. For such laminates, because by Eq. (5.6.27) $\overline{Q}_{16}$ and $\overline{Q}_{26}$are zero for every layer, all 16 and 26 terms and $\hat{N}_{xy}^T$ and $\hat{M}_{xy}^T$ in Eq. (5.6.39) are zero. For a symmetric cross-ply laminate, the relations of Eq. (5.6.39) simplify even more to give what can be written as four separate equations:

$$\begin{Bmatrix} N_x \\ N_y \end{Bmatrix} = \begin{bmatrix} A_{11} & A_{12} \\ A_{12} & A_{22} \end{bmatrix} \begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_y^o \end{Bmatrix} - \begin{Bmatrix} \hat{N}_x^T \\ \hat{N}_y^T \end{Bmatrix} \Delta T \tag{5.6.47}$$

$$N_{xy} = A_{66}\gamma_{xy}^o \tag{5.6.48}$$

$$\begin{Bmatrix} M_x \\ M_y \end{Bmatrix} = \begin{bmatrix} D_{11} & D_{12} \\ D_{12} & D_{22} \end{bmatrix} \begin{Bmatrix} \kappa_x^o \\ \kappa_y^o \end{Bmatrix} \tag{5.6.49}$$

$$M_{xy} = D_{66}\kappa_y^o \tag{5.6.50}$$

The existence of the four separate relations signifies a high degree of uncoupling of various stress resultants and reference surface deformations. Again as a reminder, if the temperature is not uniform through the thickness of the laminate, then Eqs. (5.6.47) to (5.6.50) do not apply. If the layers are all isotropic, or for a single isotropic layer, the form of Eq. (5.6.39) reduces to the form of Eqs. (5.6.47) to (5.6.50).

To follow are numerical examples of the A, B, and D matrices for a number of common laminates. The numerical examples are based upon the properties for a glass-fiber-reinforced polymer having a fiber volume fraction of 60 percent, as given in Example 2.

EXAMPLE 5 $[\pm 45/0/90]_S$. The subscript S signifies that the laminate is symmetric, and because there is a $-45°$ layer for each $+45°$ layer, the laminate is balanced. Neither the 0 nor 90° layers contribute to any of the 16 terms or the unit effective thermal stress resultants.

$$\begin{bmatrix} A_{11} & A_{12} & A_{16} \\ A_{12} & A_{22} & A_{26} \\ A_{16} & A_{26} & A_{66} \end{bmatrix} = \begin{bmatrix} 27.8 & 8.55 & 0 \\ 8.55 & 27.8 & 0 \\ 0 & 0 & 9.60 \end{bmatrix} \frac{\text{MN}}{\text{m}}$$

$$\begin{bmatrix} D_{11} & D_{12} & D_{16} \\ D_{12} & D_{22} & D_{26} \\ D_{16} & D_{26} & D_{66} \end{bmatrix} = \begin{bmatrix} 2.18 & 0.961 & 0.1784 \\ 0.961 & 1.945 & 0.1784 \\ 0.1784 & 0.1784 & 1.050 \end{bmatrix} \text{N} \cdot \text{m}$$

$$\begin{Bmatrix} \hat{N}_x^T \\ \hat{N}_y^T \end{Bmatrix} = \begin{Bmatrix} 425 \\ 425 \end{Bmatrix} \frac{\text{N/m}}{°\text{C}}$$

This eight-layer laminate is called a *quasi-isotropic* laminate because the in-plane extensional stiffnesses A_{11} and A_{22} are equal, but the in-plane shear stiffness A_{66} is not related to A_{11} ($=A_{22}$), as it would be for a truly isotropic material. In addition, the bending stiffness D_{11} and D_{22} are not equal; nor are D_{16} and D_{26} zero, as they would be for a truly isotropic material, but they are equal. Note also that $\hat{N}_x^T$ and $\hat{N}_y^T$ are equal. Herein, as stated before, the thickness of a layer is taken to be 0.000125 m (0.125 mm).

EXAMPLE 6 $[\pm 60/0]_S$

$$\begin{bmatrix} A_{11} & A_{12} & A_{16} \\ A_{12} & A_{22} & A_{26} \\ A_{16} & A_{26} & A_{66} \end{bmatrix} = \begin{bmatrix} 20.8 & 6.41 & 0 \\ 6.41 & 20.8 & 0 \\ 0 & 0 & 7.20 \end{bmatrix} \frac{\text{MN}}{\text{m}}$$

$$\begin{bmatrix} D_{11} & D_{12} & D_{16} \\ D_{12} & D_{22} & D_{26} \\ D_{16} & D_{26} & D_{66} \end{bmatrix} = \begin{bmatrix} 0.675 & 0.363 & 0.0491 \\ 0.363 & 1.151 & 0.1570 \\ 0.0491 & 0.1570 & 0.400 \end{bmatrix} \text{N} \cdot \text{m}$$

$$\begin{Bmatrix} \hat{N}_x^T \\ \hat{N}_y^T \end{Bmatrix} = \begin{Bmatrix} 319 \\ 319 \end{Bmatrix} \frac{\text{N/m}}{°\text{C}}$$

This six-layer laminate is also quasi-isotropic. The bending stiffnesses D_{16} and D_{26} are not zero.

EXAMPLE 7 $[\pm 30/0]_S$

$$\begin{bmatrix} A_{11} & A_{12} & A_{16} \\ A_{12} & A_{22} & A_{26} \\ A_{16} & A_{26} & A_{66} \end{bmatrix} = \begin{bmatrix} 28.4 & 6.41 & 0 \\ 6.41 & 13.20 & 0 \\ 0 & 0 & 7.20 \end{bmatrix} \frac{\text{MN}}{\text{m}}$$

$$\begin{bmatrix} D_{11} & D_{12} & D_{16} \\ D_{12} & D_{22} & D_{26} \\ D_{16} & D_{26} & D_{66} \end{bmatrix} = \begin{bmatrix} 1.191 & 0.363 & 0.1570 \\ 0.363 & 0.636 & 0.0491 \\ 0.1570 & 0.0491 & 0.400 \end{bmatrix} \text{N} \cdot \text{m}$$

$$\begin{Bmatrix} \hat{N}_x^T \\ \hat{N}_y^T \end{Bmatrix} = \begin{Bmatrix} 315 \\ 323 \end{Bmatrix} \frac{\text{N/m}}{°\text{C}}$$

It is interesting to note the equality of some of the terms in this laminate and the $[\pm 60/0]_S$ laminate above.

EXAMPLE 8 $[\pm 30]_{2S}$. This eight-layer laminate is a symmetric and balanced *angle-ply* laminate.

$$\begin{bmatrix} A_{11} & A_{12} & A_{16} \\ A_{12} & A_{22} & A_{26} \\ A_{16} & A_{26} & A_{66} \end{bmatrix} = \begin{bmatrix} 33.4 & 10.54 & 0 \\ 10.54 & 18.15 & 0 \\ 0 & 0 & 11.60 \end{bmatrix} \frac{\text{MN}}{\text{m}}$$

$$\begin{bmatrix} D_{11} & D_{12} & D_{16} \\ D_{12} & D_{22} & D_{26} \\ D_{16} & D_{26} & D_{66} \end{bmatrix} = \begin{bmatrix} 2.78 & 0.878 & 0.314 \\ 0.878 & 1.512 & 0.0981 \\ 0.314 & 0.0981 & 0.966 \end{bmatrix} \text{N} \cdot \text{m}$$

$$\begin{Bmatrix} \hat{N}_x^T \\ \hat{N}_y^T \end{Bmatrix} = \begin{Bmatrix} 421 \\ 429 \end{Bmatrix} \frac{\text{N/m}}{°\text{C}}$$

It is interesting to compare the properties of this laminate with the $[\pm 30/0]_S$ above, which differs in thickness and the presence of 0° layers.

EXAMPLE 9 $[\pm 60/0/90]_S$

$$\begin{bmatrix} A_{11} & A_{12} & A_{16} \\ A_{12} & A_{22} & A_{26} \\ A_{16} & A_{26} & A_{66} \end{bmatrix} = \begin{bmatrix} 24.9 & 7.55 & 0 \\ 7.55 & 32.6 & 0 \\ 0 & 0 & 8.61 \end{bmatrix} \frac{\text{MN}}{\text{m}}$$

$$\begin{bmatrix} D_{11} & D_{12} & D_{16} \\ D_{12} & D_{22} & D_{26} \\ D_{16} & D_{26} & D_{66} \end{bmatrix} = \begin{bmatrix} 1.773 & 0.816 & 0.0736 \\ 0.816 & 2.65 & 0.235 \\ 0.0736 & 0.235 & 0.904 \end{bmatrix} \text{N} \cdot \text{m}$$

$$\begin{Bmatrix} \hat{N}_x^T \\ \hat{N}_y^T \end{Bmatrix} = \begin{Bmatrix} 427 \\ 423 \end{Bmatrix} \frac{\text{N/m}}{°\text{C}}$$

EXAMPLE 10 $[0/90]_{2S}$. This is an eight-layer symmetric cross-ply laminate.

$$\begin{bmatrix} A_{11} & A_{12} & A_{16} \\ A_{12} & A_{22} & A_{26} \\ A_{16} & A_{26} & A_{66} \end{bmatrix} = \begin{bmatrix} 31.7 & 4.56 & 0 \\ 4.56 & 31.7 & 0 \\ 0 & 0 & 5.62 \end{bmatrix} \frac{\text{MN}}{\text{m}}$$

$$\begin{bmatrix} D_{11} & D_{12} & D_{16} \\ D_{12} & D_{22} & D_{26} \\ D_{16} & D_{26} & D_{66} \end{bmatrix} = \begin{bmatrix} 3.12 & 0.380 & 0 \\ 0.380 & 2.17 & 0 \\ 0 & 0 & 0.468 \end{bmatrix} \text{N} \cdot \text{m}$$

$$\begin{Bmatrix} \hat{N}_x^T \\ \hat{N}_y^T \end{Bmatrix} = \begin{Bmatrix} 425 \\ 425 \end{Bmatrix} \frac{\text{N/m}}{°\text{C}}$$

This laminate could be considered quasi-isotropic also. It is interesting to note the difference in D_{11} and D_{22}. The outer 0° layers provide most of the contribution to D_{11}, while the 90° layers provide most of the contribution to D_{22}. Since the 90° layers are closer to the reference surface than the 0° layers, the bending stiffness

in the y direction, D_{22}, is less than the bending stiffness in the x direction, D_{11}. On the other hand, the four 0° layers and the four 90° layers provide the same resistance to extension in the x and y directions, respectively, so $A_{22} = A_{11}$.

EXAMPLE 11 $[0_4/90_4]_T$. This an eight-layer *antisymmetric* cross-ply laminate.

$$\begin{bmatrix} A_{11} & A_{12} & A_{16} & B_{11} & B_{12} & B_{16} \\ A_{12} & A_{22} & A_{26} & B_{12} & B_{22} & B_{26} \\ A_{16} & A_{26} & A_{66} & B_{16} & B_{26} & B_{66} \\ B_{11} & B_{12} & B_{16} & D_{11} & D_{12} & D_{16} \\ B_{12} & B_{22} & B_{26} & D_{12} & D_{22} & D_{26} \\ B_{16} & B_{26} & B_{66} & D_{16} & D_{26} & D_{66} \end{bmatrix}$$

$$= \begin{bmatrix} 31.7\,\frac{\text{MN}}{\text{m}} & 4.56\,\frac{\text{MN}}{\text{m}} & 0 & -3{,}810\,\text{N} & 0 & 0 \\ 4.56\,\frac{\text{MN}}{\text{m}} & 31.7\,\frac{\text{MN}}{\text{m}} & 0 & 0 & 3{,}810\,\text{N} & 0 \\ 0 & 0 & 5.62\,\frac{\text{MN}}{\text{m}} & 0 & 0 & 0 \\ -3{,}810\,\text{N} & 0 & 0 & 2.65\,\frac{\text{N}}{\text{m}} & 0.380\,\frac{\text{N}}{\text{m}} & 0 \\ 0 & 3{,}810\,\text{N} & 0 & 0.380\,\frac{\text{N}}{\text{m}} & 2.65\,\frac{\text{N}}{\text{m}} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0.468\,\frac{\text{N}}{\text{m}} \end{bmatrix}$$

$$\begin{Bmatrix} \hat{N}_x^T \\ \hat{N}_y^T \\ \hat{N}_{xy}^T \\ \hat{M}_x^T \\ \hat{M}_y^T \\ \hat{M}_{xy}^T \end{Bmatrix} = \begin{Bmatrix} 425\,\frac{\text{N/m}}{\text{°C}} \\ 425\,\frac{\text{N/m}}{\text{°C}} \\ 0 \\ 19.77 \times 10^{-4}\,\frac{\text{N}}{\text{°C}} \\ -19.77 \times 10^{-4}\,\frac{\text{N}}{\text{°C}} \\ 0 \end{Bmatrix}$$

The only terms in the B matrix are B_{11}, which equals $-B_{22}$, but this single coupling term can cause interesting effects. There are also thermally induced moments, which cause this laminate to curl out of plane when cooled from its elevated curing temperature. The two unit equivalent thermal moment resultants are equal in magnitude and opposite in sign. Note that the A matrix is the same as for the previous cross-ply laminate, Example 10.

INVERSE RELATIONS

Generally the force and moment resultants and temperature change are known for an element of laminate, and it is of interest to compute the strains and stresses in individual layers, or throughout the entire thickness of the laminate if a complete stress analysis is desired. It is convenient to invert the relations previously discussed so the reference surface strains and curvatures can be computed more easily. For a general laminate, from Eq. (5.6.39), the inverse relation is

$$\begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_y^o \\ \gamma_{xy}^o \\ \kappa_x^o \\ \kappa_y^o \\ \kappa_{xy}^o \end{Bmatrix} = \begin{bmatrix} a_{11} & a_{12} & a_{16} & b_{11} & b_{12} & b_{16} \\ a_{12} & a_{22} & a_{26} & b_{21} & b_{22} & b_{26} \\ a_{16} & a_{26} & a_{66} & b_{61} & b_{62} & b_{66} \\ b_{11} & b_{21} & b_{61} & d_{11} & d_{12} & d_{16} \\ b_{12} & b_{22} & b_{62} & d_{12} & d_{22} & d_{26} \\ b_{16} & b_{26} & b_{66} & d_{16} & d_{26} & d_{66} \end{bmatrix} \left(\begin{Bmatrix} N_x \\ N_y \\ N_{xy} \\ M_x \\ M_y \\ M_{xy} \end{Bmatrix} + \begin{Bmatrix} \hat{N}_x^T \\ \hat{N}_y^T \\ \hat{N}_{xy}^T \\ \hat{M}_x^T \\ \hat{M}_y^T \\ \hat{M}_{xy}^T \end{Bmatrix} \Delta T \right) \tag{5.6.51}$$

where

$$\begin{bmatrix} a_{11} & a_{12} & a_{16} & b_{11} & b_{12} & b_{16} \\ a_{12} & a_{22} & a_{26} & b_{21} & b_{22} & b_{26} \\ a_{16} & a_{26} & a_{66} & b_{61} & b_{62} & b_{66} \\ b_{11} & b_{21} & b_{61} & d_{11} & d_{12} & d_{16} \\ b_{12} & b_{22} & b_{62} & d_{12} & d_{22} & d_{26} \\ b_{16} & b_{26} & b_{66} & d_{16} & d_{26} & d_{66} \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} & A_{16} & B_{11} & B_{12} & B_{16} \\ A_{12} & A_{22} & A_{26} & B_{12} & B_{22} & B_{26} \\ A_{16} & A_{26} & A_{66} & B_{16} & B_{26} & B_{66} \\ B_{11} & B_{12} & B_{16} & D_{11} & D_{12} & D_{16} \\ B_{12} & B_{22} & B_{26} & D_{12} & D_{22} & D_{26} \\ B_{16} & B_{26} & B_{66} & D_{16} & D_{26} & D_{66} \end{bmatrix}^{-1} \tag{5.6.52}$$

is the **laminate compliance matrix** or **ABD inverse matrix.**

For a symmetric balanced laminate, the inverses of Eqs. (5.6.44) to (5.6.46) are

$$\begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_y^o \end{Bmatrix} = \begin{bmatrix} a_{11} & a_{12} \\ a_{12} & a_{22} \end{bmatrix} \begin{Bmatrix} N_x + \hat{N}_x^T \Delta T \\ N_y + \hat{N}_y^T \Delta T \end{Bmatrix} \tag{5.6.53}$$

$$\gamma_{xy}^o = a_{66} N_{xy} \tag{5.6.54}$$

$$\begin{Bmatrix} \kappa_x^o \\ \kappa_y^o \\ \kappa_{xy}^o \end{Bmatrix} = \begin{bmatrix} d_{11} & d_{12} & d_{16} \\ d_{12} & d_{22} & d_{26} \\ d_{16} & d_{26} & d_{66} \end{bmatrix} \begin{Bmatrix} M_x \\ M_y \\ M_{xy} \end{Bmatrix} = [d] \begin{Bmatrix} M_x \\ M_y \\ M_{xy} \end{Bmatrix} \tag{5.6.55}$$

where

$$\begin{bmatrix} a_{11} & a_{12} & 0 \\ a_{12} & a_{22} & 0 \\ 0 & 0 & a_{66} \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} & 0 \\ A_{12} & A_{22} & 0 \\ 0 & 0 & A_{66} \end{bmatrix}^{-1}$$
$$\begin{bmatrix} d_{11} & d_{12} & d_{16} \\ d_{12} & d_{22} & d_{26} \\ d_{16} & d_{26} & d_{66} \end{bmatrix} = \begin{bmatrix} D_{11} & D_{12} & D_{16} \\ D_{12} & D_{22} & D_{26} \\ D_{16} & D_{26} & D_{66} \end{bmatrix}^{-1} \tag{5.6.56}$$

The inverse matrices, namely the compliance matrices, are actually more useful than the stiffness matrices for computing the reference surface strains and curvatures from the force and moment resultants. For a symmetric cross-ply laminate, the inverse relations are determined from Eqs. (5.6.47) to (5.6.50) as

$$\begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_y^o \end{Bmatrix} = \begin{bmatrix} a_{11} & a_{12} \\ a_{12} & a_{22} \end{bmatrix} \begin{Bmatrix} N_x + \hat{N}_x^T \Delta T \\ N_y + \hat{N}_y^T \Delta T \end{Bmatrix} \tag{5.6.57}$$

$$\gamma_{xy}^o = a_{66} N_{xy} \tag{5.6.58}$$

$$\begin{Bmatrix} \kappa_x^o \\ \kappa_y^o \end{Bmatrix} = \begin{bmatrix} d_{11} & d_{12} \\ d_{12} & d_{22} \end{bmatrix} \begin{Bmatrix} M_x \\ M_y \end{Bmatrix} \tag{5.6.59}$$

$$\kappa_{xy}^o = d_{66} M_{xy} \tag{5.6.60}$$

where the compliance matrices are given by

$$\begin{bmatrix} a_{11} & a_{12} & 0 \\ a_{12} & a_{22} & 0 \\ 0 & 0 & a_{66} \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} & 0 \\ A_{12} & A_{22} & 0 \\ 0 & 0 & A_{66} \end{bmatrix}^{-1}$$
$$\begin{bmatrix} d_{11} & d_{12} & 0 \\ d_{12} & d_{22} & 0 \\ 0 & 0 & d_{66} \end{bmatrix} = \begin{bmatrix} D_{11} & D_{12} & 0 \\ D_{12} & D_{22} & 0 \\ 0 & 0 & D_{66} \end{bmatrix}^{-1} \tag{5.6.61}$$

The numerical values of the compliance matrices for the laminates discussed in Examples 5 to 11 above are as follows:

EXAMPLE 12 $[\pm 45/0/90]_S$

$$\begin{bmatrix} a_{11} & a_{12} & a_{16} \\ a_{12} & a_{22} & a_{26} \\ a_{16} & a_{26} & a_{66} \end{bmatrix} = \begin{bmatrix} 39.8 & -12.26 & 0 \\ -12.26 & 39.8 & 0 \\ 0 & 0 & 104.1 \end{bmatrix} \frac{\text{m}}{\text{GN}}$$
$$\begin{bmatrix} d_{11} & d_{12} & d_{16} \\ d_{12} & d_{22} & d_{26} \\ d_{16} & d_{26} & d_{66} \end{bmatrix} = \begin{bmatrix} 0.588 & -0.286 & -0.0514 \\ -0.286 & 0.662 & -0.0638 \\ -0.0514 & -0.0638 & 0.972 \end{bmatrix} \frac{1}{\text{N·m}}$$

where, for example,

$$39.8\,\frac{\text{m}}{\text{GN}} = 39.8\,\frac{\text{m}}{10^9\,\text{N}} = 39.8 \times 10^{-9}\,\frac{\text{m}}{\text{N}}$$

EXAMPLE 13 $[\pm 60/0]_S$

$$\begin{bmatrix} a_{11} & a_{12} & a_{16} \\ a_{12} & a_{22} & a_{26} \\ a_{16} & a_{26} & a_{66} \end{bmatrix} = \begin{bmatrix} 53.1 & -16.34 & 0 \\ -16.34 & 53.1 & 0 \\ 0 & 0 & 138.8 \end{bmatrix} \frac{\text{m}}{\text{GN}}$$

$$\begin{bmatrix} d_{11} & d_{12} & d_{16} \\ d_{12} & d_{22} & d_{26} \\ d_{16} & d_{26} & d_{66} \end{bmatrix} = \begin{bmatrix} 1.782 & -0.562 & 0.001835 \\ -0.562 & 1.095 & -0.361 \\ 0.001835 & -0.361 & 2.64 \end{bmatrix} \frac{1}{\text{N} \cdot \text{m}}$$

EXAMPLE 14 $[\pm 30/0]_S$

$$\begin{bmatrix} a_{11} & a_{12} & a_{16} \\ a_{12} & a_{22} & a_{26} \\ a_{16} & a_{26} & a_{66} \end{bmatrix} = \begin{bmatrix} 39.5 & -19.18 & 0 \\ -19.18 & 85.1 & 0 \\ 0 & 0 & 138.8 \end{bmatrix} \frac{\text{m}}{\text{GN}}$$

$$\begin{bmatrix} d_{11} & d_{12} & d_{16} \\ d_{12} & d_{22} & d_{26} \\ d_{16} & d_{26} & d_{66} \end{bmatrix} = \begin{bmatrix} 1.062 & -0.579 & -0.346 \\ -0.579 & 1.903 & -0.00631 \\ -0.346 & -0.00631 & 2.64 \end{bmatrix} \frac{1}{\text{N} \cdot \text{m}}$$

EXAMPLE 15 $[\pm 30]_{2S}$

$$\begin{bmatrix} a_{11} & a_{12} & a_{16} \\ a_{12} & a_{22} & a_{26} \\ a_{16} & a_{26} & a_{66} \end{bmatrix} = \begin{bmatrix} 36.7 & -21.3 & 0 \\ -21.3 & 67.5 & 0 \\ 0 & 0 & 86.2 \end{bmatrix} \frac{\text{m}}{\text{GN}}$$

$$\begin{bmatrix} d_{11} & d_{12} & d_{16} \\ d_{12} & d_{22} & d_{26} \\ d_{16} & d_{26} & d_{66} \end{bmatrix} = \begin{bmatrix} 0.454 & -0.256 & -0.1215 \\ -0.256 & 0.810 & 0.000881 \\ -0.1215 & 0.000881 & 1.074 \end{bmatrix} \frac{1}{\text{N} \cdot \text{m}}$$

EXAMPLE 16 $[\pm 60/0/90]_S$

$$\begin{bmatrix} a_{11} & a_{12} & a_{16} \\ a_{12} & a_{22} & a_{26} \\ a_{16} & a_{26} & a_{66} \end{bmatrix} = \begin{bmatrix} 43.1 & -10.00 & 0 \\ -10.00 & 33.0 & 0 \\ 0 & 0 & 116.2 \end{bmatrix} \frac{\text{m}}{\text{GN}}$$

$$\begin{bmatrix} d_{11} & d_{12} & d_{16} \\ d_{12} & d_{22} & d_{26} \\ d_{16} & d_{26} & d_{66} \end{bmatrix} = \begin{bmatrix} 0.657 & -0.203 & -0.000718 \\ -0.203 & 0.450 & -0.1006 \\ -0.000718 & -0.1006 & 1.132 \end{bmatrix} \frac{1}{\text{N} \cdot \text{m}}$$

EXAMPLE 17 $[0/90]_{2S}$

$$\begin{bmatrix} a_{11} & a_{12} & a_{16} \\ a_{12} & a_{22} & a_{26} \\ a_{16} & a_{26} & a_{66} \end{bmatrix} = \begin{bmatrix} 32.2 & -4.62 & 0 \\ -4.62 & 32.2 & 0 \\ 0 & 0 & 178.0 \end{bmatrix} \frac{\text{m}}{\text{GN}}$$

$$\begin{bmatrix} d_{11} & d_{12} & d_{16} \\ d_{12} & d_{22} & d_{26} \\ d_{16} & d_{26} & d_{66} \end{bmatrix} = \begin{bmatrix} 0.327 & -0.0573 & 0 \\ -0.0573 & 0.471 & 0 \\ 0 & 0 & 2.14 \end{bmatrix} \frac{1}{\text{N} \cdot \text{m}}$$

EXAMPLE 18 $[0_4/90_4]_T$

$$\begin{bmatrix} a_{11} & a_{12} & a_{16} & b_{11} & b_{12} & b_{16} \\ a_{12} & a_{22} & a_{26} & b_{21} & b_{22} & b_{26} \\ a_{16} & a_{26} & a_{66} & b_{61} & b_{62} & b_{66} \\ b_{11} & b_{21} & b_{61} & d_{11} & d_{12} & d_{16} \\ b_{12} & b_{22} & b_{62} & d_{12} & d_{22} & d_{26} \\ b_{16} & b_{26} & b_{66} & d_{16} & d_{26} & d_{66} \end{bmatrix}$$

$$= \begin{bmatrix} 39.1 \frac{\text{m}}{\text{GN}} & -5.61 \frac{\text{m}}{\text{GN}} & 0 & 5.62 \times 10^{-5} \frac{1}{\text{N}} & 0 & 0 \\ -5.61 \frac{\text{m}}{\text{GN}} & 39.1 \frac{\text{m}}{\text{GN}} & 0 & 0 & -5.62 \times 10^{-5} \frac{1}{\text{N}} & 0 \\ 0 & 0 & 178.0 \frac{\text{m}}{\text{GN}} & 0 & 0 & 0 \\ 5.62 \times 10^{-5} \frac{1}{\text{N}} & 0 & 0 & 0.469 \frac{\text{m}}{\text{N}} & -0.0673 \frac{\text{m}}{\text{N}} & 0 \\ 0 & -5.62 \times 10^{-5} \frac{1}{\text{N}} & 0 & -0.0673 \frac{\text{m}}{\text{N}} & 0.469 \frac{\text{m}}{\text{N}} & 0 \\ 0 & 0 & 0 & 0 & 0 & 2.14 \frac{\text{m}}{\text{N}} \end{bmatrix}$$

It is interesting to note that while a_{16} and a_{26} are always negative, the sign and existence of d_{16} and d_{26} vary with the laminate. This has implications regarding the directions of the curvatures produced by applied moments, particularly the twist quantities.

LAMINATE STRESS ANALYSIS

With what has been presented, it is now possible to compute the stresses in an element of a laminate that is loaded by known applied force and moment resultants and that is subjected to a temperature change. The material properties, fiber orientation, and z coordinates of each layer lead to numerical values for the elements of the A, B, and D matrices and unit effective thermal stress resultants. Given the magnitude and direction of the applied loads and the dimensions of the element, the force and moment resultants can be determined. The strains and curvatures of the reference surface can be computed by using the various inverse relations of the previous section, depending on the particular laminate. The strains at every z location through the thickness of the laminate can be determined from Eq. (5.6.29). These strains, in turn, can be transformed by using Eq. (5.6.24) to determine the strains in the principal material coordinate system at every z location. These strains can then be used in Eq. (5.6.20) to compute the stresses in the principal material coordinate system at every z location. The approach is very systematic, the procedures to employ at each step are straightforward and well defined, and numerical values can be determined. It goes without saying that these steps are best executed by programming a calculator or computer to deal with the many algebraic relations. Executing the many algebraic steps by hand is very error-prone. However, any program should be thoroughly checked to be sure it is computing what is intended before the results of the program are used for analysis and design. Once checked for accuracy, the program can be very useful.

Below are several examples that demonstrate the use of the steps described above to compute the stresses within a laminate.

EXAMPLE 19. Consider a flat six-layer $[\pm 30/0]_S$ laminate with in-plane dimensions 0.35 m by 0.25 m subjected to a force of 15,000 N in the x direction uniformly distributed along opposite edges, as shown in Fig. 5.6.12. The temperature change from the cure condition is $\Delta T = -100°\text{C}$. Compute the stresses in each layer.

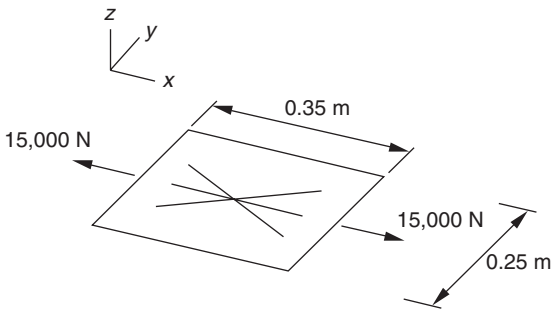

Fig. 5.6.12 Laminate loaded in x direction.

APPROACH. The relations between stress resultants and deformations and the deformations and stresses, and the transformation relations, all outlined above are applied to the problem to determine the desired answers. Note that the laminate is symmetric and balanced, so Eqs. (5.6.53) to (5.6.55) apply, and only a single force is applied. This should considerably simplify the calculations.

SOLUTION. Except for the effective thermal stress resultants, N_x is the only stress resultant, and since the force is uniformly distributed, it is given by

$$N_x = \frac{15{,}000 \text{ N}}{0.25 \text{ m}} = 60{,}000 \text{ N/m}$$

The unit effective thermal stress resultants consist of just two components given by Example 7, namely,

$$\begin{Bmatrix} \hat{N}_x^T \\ \hat{N}_y^T \\ \hat{N}_{xy}^T \end{Bmatrix} = \begin{Bmatrix} 315 \\ 323 \\ 0 \end{Bmatrix} \frac{\text{N/m}}{°\text{C}}$$

Since there are no moment resultants, the reference surface curvatures are zero. The two reference surface strains are given by direct application of Eqs. (5.6.53) and (5.6.54), with numerical values from Example 14, to yield

$$\begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_y^o \\ \gamma_{xy}^o \end{Bmatrix} = \begin{bmatrix} a_{11} & a_{12} & 0 \\ a_{12} & a_{22} & 0 \\ 0 & 0 & a_{66} \end{bmatrix} \begin{Bmatrix} N_x + \hat{N}_x^T \Delta T \\ N_y + \hat{N}_y^T \Delta T \\ N_{xy} + \hat{N}_{xy}^T \Delta T \end{Bmatrix}$$

$$= \begin{bmatrix} 39.5 & -19.18 & 0 \\ -19.18 & 85.1 & 0 \\ 0 & 0 & 138.8 \end{bmatrix} \times 10^{-9} \begin{Bmatrix} 60{,}000 + 315(-100) \\ 323(-100) \\ 0 \end{Bmatrix}$$

$$\text{or} \quad \begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_y^o \\ \gamma_{xy}^o \end{Bmatrix} = \begin{Bmatrix} 2{,}370 \\ -1{,}151 \\ 0 \end{Bmatrix} \times 10^{-6} + \begin{Bmatrix} -625 \\ -2{,}140 \\ 0 \end{Bmatrix} \times 10^{-6} = \begin{Bmatrix} 1{,}745 \\ -3{,}290 \\ 0 \end{Bmatrix} \times 10^{-6}$$

The first term after the first equals sign is the strains due to the applied force, and the second term is the strains due to the decrease in temperature. Due to the applied force, the element of laminate stretches in the direction of the applied force, contracts perpendicular to that direction, and experiences no shear strain. Due to thermal effects, the element of laminate contracts in both directions, but more in the y direction. The net effect is stretching in the direction of the applied force and considerable contraction perpendicular to that direction, mostly due to thermal effects.

Transforming the strains to the principal material coordinate system for each fiber orientation from Eq. (5.6.24) results in

$$\begin{Bmatrix} \varepsilon_1^o(30°) \\ \varepsilon_2^o(30°) \\ \frac{1}{2}\gamma_{12}^o(30°) \end{Bmatrix} = [T(30°)] \begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_y^o \\ \frac{1}{2}\gamma_{xy}^o \end{Bmatrix}$$

$$= \begin{bmatrix} \frac{3}{4} & \frac{1}{4} & \frac{\sqrt{3}}{2} \\ \frac{1}{4} & \frac{3}{4} & -\frac{\sqrt{3}}{2} \\ -\frac{\sqrt{3}}{4} & \frac{\sqrt{3}}{4} & \frac{1}{2} \end{bmatrix} \begin{Bmatrix} 1{,}745 \\ -3{,}290 \\ 0 \end{Bmatrix} \times 10^{-6}$$

$$= \begin{Bmatrix} 486 \\ -2{,}030 \\ -2{,}180 \end{Bmatrix} \times 10^{-6}$$

$$\begin{Bmatrix} \varepsilon_1^o(-30°) \\ \varepsilon_2^o(-30°) \\ \frac{1}{2}\gamma_{12}^o(-30°) \end{Bmatrix} = [T(-30°)] \begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_y^o \\ \frac{1}{2}\gamma_{xy}^o \end{Bmatrix}$$

$$= \begin{bmatrix} \frac{3}{4} & \frac{1}{4} & -\frac{\sqrt{3}}{2} \\ \frac{1}{4} & \frac{3}{4} & \frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{4} & -\frac{\sqrt{3}}{4} & \frac{1}{2} \end{bmatrix} \begin{Bmatrix} 1{,}745 \\ -3{,}290 \\ 0 \end{Bmatrix} \times 10^{-6}$$

$$= \begin{Bmatrix} 486 \\ -2{,}030 \\ 2{,}180 \end{Bmatrix} \times 10^{-6}$$

$$\begin{Bmatrix} \varepsilon_1^o(0°) \\ \varepsilon_2^o(0°) \\ \frac{1}{2}\gamma_{12}^o(0°) \end{Bmatrix} = [T(0°)] \begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_y^o \\ \frac{1}{2}\gamma_{xy}^o \end{Bmatrix}$$

$$= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{Bmatrix} 1{,}745 \\ -3{,}290 \\ 0 \end{Bmatrix} \times 10^{-6} = \begin{Bmatrix} 1{,}745 \\ -3{,}290 \\ 0 \end{Bmatrix} \times 10^{-6}$$

In the principal material coordinate system there are substantial shear strains in the $\pm 30°$ layers, and they are of opposite sign. The extensional strains are identical. Of course, no transformation is necessary for the 0° layers. Substituting the strains for each layer into the stress-strain relation of Eq. (5.6.20) provides the desired stresses:

$$\begin{Bmatrix} \sigma_1(+30°) \\ \sigma_2(+30°) \\ \tau_{12}(+30°) \end{Bmatrix} = \begin{pmatrix} Q_{11} & Q_{12} & 0 \\ Q_{12} & Q_{22} & 0 \\ 0 & 0 & Q_{66} \end{pmatrix} \begin{Bmatrix} \varepsilon_1(+30°) - \alpha_1 \Delta T \\ \varepsilon_2(+30°) - \alpha_2 \Delta T \\ \gamma_{12}(+30°) \end{Bmatrix}$$

$$\begin{Bmatrix} \sigma_1(+30°) \\ \sigma_2(+30°) \\ \tau_{12}(+30°) \end{Bmatrix} = \begin{pmatrix} 47.0 & 4.56 & 0 \\ 4.56 & 16.51 & 0 \\ 0 & 0 & 5.62 \end{pmatrix}$$

$$\times 10^9 \begin{Bmatrix} 486 - 6.51(-100) \\ -2{,}030 - 24.4(-100) \\ -4{,}360 \end{Bmatrix} \times 10^{-6} = \begin{Bmatrix} 55.3 \\ 11.94 \\ -24.5 \end{Bmatrix} \text{MPa}$$

$$\begin{Bmatrix} \sigma_1(-30°) \\ \sigma_2(-30°) \\ \tau_{12}(-30°) \end{Bmatrix} = \begin{pmatrix} Q_{11} & Q_{12} & 0 \\ Q_{12} & Q_{22} & 0 \\ 0 & 0 & Q_{66} \end{pmatrix} \begin{Bmatrix} \varepsilon_1(-30°) - \alpha_1 \Delta T \\ \varepsilon_2(-30°) - \alpha_2 \Delta T \\ \gamma_{12}\ (-30°) \end{Bmatrix}$$

$$\begin{Bmatrix} \sigma_1(-30°) \\ \sigma_2(-30°) \\ \tau_{12}(-30°) \end{Bmatrix} = \begin{pmatrix} 47.0 & 4.56 & 0 \\ 4.56 & 16.51 & 0 \\ 0 & 0 & 5.62 \end{pmatrix}$$

$$\times 10^9 \begin{Bmatrix} 486 - 6.51(-100) \\ -2{,}030 - 24.4(-100) \\ 4{,}360 \end{Bmatrix} \times 10^{-6} = \begin{Bmatrix} 55.3 \\ 11.94 \\ 24.5 \end{Bmatrix} \text{MPa}$$

$$\begin{Bmatrix} \sigma_1(0°) \\ \sigma_2(0°) \\ \tau_{12}(0°) \end{Bmatrix} = \begin{pmatrix} Q_{11} & Q_{12} & 0 \\ Q_{12} & Q_{22} & 0 \\ 0 & 0 & Q_{66} \end{pmatrix} \begin{Bmatrix} \varepsilon_1(0°) - \alpha_1 \Delta T \\ \varepsilon_2(0°) - \alpha_2 \Delta T \\ \gamma_{12}(0°) \end{Bmatrix}$$

$$\begin{Bmatrix} \sigma_1(0°) \\ \sigma_2(0°) \\ \tau_{12}(0°) \end{Bmatrix} = \begin{pmatrix} 47.0 & 4.56 & 0 \\ 4.56 & 16.51 & 0 \\ 0 & 0 & 5.62 \end{pmatrix}$$

$$\times 10^9 \begin{Bmatrix} 1{,}745 - 6.51(-100) \\ -3{,}290 - 24.4(-100) \\ 0 \end{Bmatrix} \times 10^{-6} = \begin{Bmatrix} 108.7 \\ -3.11 \\ 0 \end{Bmatrix} \text{MPa}$$

As might be expected, the stress in the fiber direction in the 0° layers is the highest. The $\pm 30°$ layers experience a shear stress. If thermal effects were ignored, ΔT would be taken to be zero, resulting in

$$\begin{Bmatrix} \sigma_1(+30°) \\ \sigma_2(+30°) \\ \sigma_{12}(+30°) \end{Bmatrix} = \begin{Bmatrix} 68.7 \\ 2.33 \\ -17.12 \end{Bmatrix} \text{MPa} \qquad \begin{Bmatrix} \sigma_1(-30°) \\ \sigma_2(-30°) \\ \sigma_{12}(-30°) \end{Bmatrix} = \begin{Bmatrix} 68.7 \\ 2.33 \\ 17.12 \end{Bmatrix} \text{MPa}$$

$$\begin{Bmatrix} \sigma_1(0°) \\ \sigma_2(0°) \\ \tau_{12}(0°) \end{Bmatrix} = \begin{Bmatrix} 106.1 \\ -8.20 \\ 0 \end{Bmatrix} \text{MPa}$$

It can be seen that residual thermal effects increase some stress components and decrease others. Even though some stress components are small compared to others, e.g., σ_2 compared to σ_1, the material is much weaker perpendicular to the fibers than in the fiber direction. The small stress may be approaching levels to cause failure perpendicular to the fibers.

Figure 5.6.13 shows the variation through the thickness of the three components of stress in the principal material coordinate system. The stresses are constant within each layer, but the overall distributions through the thickness are discontinuous, a characteristic which makes composite materials different from

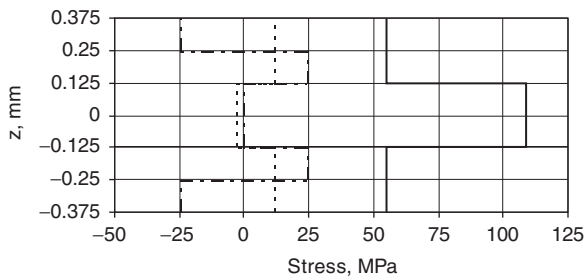

Fig. 5.6.13 Through-thickness distribution of stresses: σ_1, solid; σ_2, dotted; τ_{12}, dashed.

conventional materials such as aluminum or steel. For aluminum or steel, for example, the stress distributions through the thickness would be continuous and there would be no shear stress. Note that there is no net shear stress for the laminate, although there are shear strains, but of opposite sign, for the $\pm 30°$ layers. This characteristic is due to the balanced nature of the laminate.

EXAMPLE 20. A flat eight-layer $[\pm 45/0/90]_S$ quasi-isotropic laminate 0.1 by 0.4 m is loaded by a 0.7 N · m moment, as shown in Fig. 5.6.14. The through-thickness distribution of the stresses in the principal material coordinate system is of interest. The temperature change from the cure temperature condition is −100°C.

APPROACH. The symmetric and balanced nature of the laminate, along with the fact that only a single moment is applied, simplifies the computations considerably. Equations (5.6.53) to (5.6.55) and the material properties from Examples 5 and 12 apply.

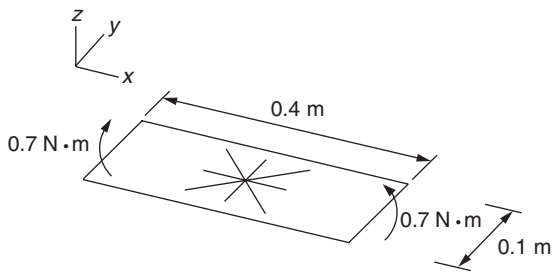

Fig. 5.6.14 Laminate loaded by moment.

SOLUTION. If it is assumed that the applied moment is uniformly distributed along the opposite edges, the moment resultant is given by

$$M_x = \frac{-0.7}{0.1} = -7 \text{ N} \cdot \text{m/m}$$

The values of M_y and M_{xy} are zero. There are no unit equivalent thermal moment resultants, and the unit equivalent thermal force resultants are given in Example 5 as

$$\begin{Bmatrix} \hat{N}_x^T \\ \hat{N}_y^T \\ \hat{N}_{xy}^T \end{Bmatrix} = \begin{Bmatrix} 425 \\ 425 \\ 0 \end{Bmatrix} \frac{\text{N/m}}{^\circ\text{C}}$$

The reference surface strains are due only to the equivalent thermal force resultants and are computed as follows by way of Eqs. (5.6.53) and (5.6.54), with numerical values from Example 12, as

$$\begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_y^o \\ \gamma_{xy}^o \end{Bmatrix} = \begin{bmatrix} a_{11} & a_{12} & 0 \\ a_{12} & a_{22} & 0 \\ 0 & 0 & a_{66} \end{bmatrix} \begin{Bmatrix} \hat{N}_x^T \Delta T \\ \hat{N}_y^T \Delta T \\ \hat{N}_{xy}^T \Delta T \end{Bmatrix}$$

$$= \begin{bmatrix} 39.8 & -12.26 & 0 \\ -12.26 & 39.8 & 0 \\ 0 & 0 & 104.1 \end{bmatrix} \times 10^{-9} \begin{Bmatrix} 425(-100) \\ 425(-100) \\ 0 \end{Bmatrix}$$

$$= \begin{Bmatrix} -1{,}171 \\ -1{,}171 \\ 0 \end{Bmatrix} \times 10^{-6}$$

The reference surface curvatures are due to the applied moment and are computed by way of Eq. (5.6.55) and Example 12 as

$$\begin{Bmatrix} \kappa_x^o \\ \kappa_y^o \\ \kappa_{xy}^o \end{Bmatrix} = \begin{bmatrix} d_{11} & d_{12} & d_{16} \\ d_{12} & d_{22} & d_{26} \\ d_{16} & d_{26} & d_{66} \end{bmatrix} \begin{Bmatrix} M_x \\ M_y \\ M_{xy} \end{Bmatrix}$$

$$= \begin{bmatrix} 0.588 & -0.286 & -0.0514 \\ -0.286 & 0.662 & -0.0638 \\ -0.0514 & -0.0638 & 0.972 \end{bmatrix} \begin{Bmatrix} -7 \\ 0 \\ 0 \end{Bmatrix} \frac{1}{\text{m}} = \begin{Bmatrix} -4.12 \\ 2.00 \\ 0.360 \end{Bmatrix} \frac{1}{\text{m}}$$

Note that in addition to producing curvature component κ_x^o, as expected, the single moment M_x produces curvature components κ_y^o and κ_{xy}^o. The former curvature would exist if this were a conventional material such as aluminum or steel, and it is called the *anticlastic* curvature. It is due to Poisson's ratio, which is reflected in the value of d_{12} and is related to $\overline{Q}_{12}$. The twist curvature κ_{xy}^o is due to the existence of d_{16}, which can be related to the existence of nonzero values of $\overline{Q}_{16}$ in the $\pm 45^\circ$ layers. Twist curvature would not exist if this were a conventional material.

The strain as a function of z in the laminate coordinate system is given by Eq. (5.6.29) as

$$\begin{Bmatrix} \varepsilon_x \\ \varepsilon_y \\ \gamma_{xy} \end{Bmatrix} = \begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_y^o \\ \gamma_{xy}^o \end{Bmatrix} + z \begin{Bmatrix} \kappa_x^o \\ \kappa_y^o \\ \kappa_{xy}^o \end{Bmatrix} = \begin{Bmatrix} -1{,}171 \\ -1{,}171 \\ 0 \end{Bmatrix} \times 10^{-6} + z \begin{Bmatrix} -4.12 \\ 2.00 \\ 0.360 \end{Bmatrix}$$

These relations are valid for the full range of z, $-0.000500 \text{ m} \le z \le +0.000500$ m. Transforming these strains to the principal material coordinate system by way of Eq. (5.6.24) for the various fiber orientations gives the following:

For $-0.000500 \text{ m} \le z \le -0.000375$ m and $0.000375 \text{ m} \le z \le 0.000500$ m,

$$\begin{Bmatrix} \varepsilon_1(45^\circ) \\ \varepsilon_2(45^\circ) \\ \frac{1}{2}\gamma_{12}(45^\circ) \end{Bmatrix} = [T(45^\circ)] \begin{Bmatrix} \varepsilon_x \\ \varepsilon_y \\ \frac{1}{2}\gamma_{xy} \end{Bmatrix}$$

$$= \begin{bmatrix} \frac{1}{2} & \frac{1}{2} & 1 \\ \frac{1}{2} & \frac{1}{2} & -1 \\ -\frac{1}{2} & \frac{1}{2} & 0 \end{bmatrix} \begin{Bmatrix} -1{,}171 \times 10^{-6} - 4.12z \\ -1{,}171 \times 10^{-6} + 2.00z \\ 0.180z \end{Bmatrix}$$

$$= \begin{Bmatrix} -1{,}171 \times 10^{-6} - 0.878z \\ -1{,}171 \times 10^{-6} - 1.238z \\ 3.06z \end{Bmatrix}$$

For $-0.000375 \text{ m} \le z \le -0.000250$ m and $0.000250 \text{ m} \le z \le 0.000375$ m,

$$\begin{Bmatrix} \varepsilon_1(-45^\circ) \\ \varepsilon_2(-45^\circ) \\ \frac{1}{2}\gamma_{12}(-45^\circ) \end{Bmatrix} = \begin{Bmatrix} -1{,}171 \times 10^{-6} - 1.238z \\ -1{,}171 \times 10^{-6} - 0.878z \\ -3.06z \end{Bmatrix}$$

For $-0.000250 \text{ m} \le z \le -0.000125$ m and $0.000125 \text{ m} \le z \le 0.000250$ m,

$$\begin{Bmatrix} \varepsilon_1(0^\circ) \\ \varepsilon_2(0^\circ) \\ \frac{1}{2}\gamma_{12}(0^\circ) \end{Bmatrix} = \begin{Bmatrix} -1{,}171 \times 10^{-6} - 4.12z \\ -1{,}171 \times 10^{-6} + 2.00z \\ 0.1799z \end{Bmatrix}$$

For $-0.000125 \text{ m} \le z \le 0.000125$ m,

$$\begin{Bmatrix} \varepsilon_1(90^\circ) \\ \varepsilon_2(90^\circ) \\ \frac{1}{2}\gamma_{12}(90^\circ) \end{Bmatrix} = \begin{Bmatrix} -1{,}171 \times 10^{-6} + 2.00z \\ -1{,}171 \times 10^{-6} - 4.12z \\ -0.1799z \end{Bmatrix}$$

Note that each equation is valid for two ranges of z, the ranges depending on the z location of the layers with the different fiber orientations. The stresses in the various layers in the principal material coordinate system can be computed directly from Eq. (5.6.20) by using the above strains. Again there is a range of z for each relation, depending on the layer. The stresses in the principal material coordinate system are as follows:

For $-0.000500 \text{ m} \le z \le -0.000375$ m and $0.000375 \text{ m} \le z \le 0.000500$ m,

$$\begin{Bmatrix} \sigma_1(45^\circ) \\ \sigma_2(45^\circ) \\ \tau_{12}(45^\circ) \end{Bmatrix} = \begin{bmatrix} Q_{11} & Q_{12} & 0 \\ Q_{12} & Q_{22} & 0 \\ 0 & 0 & Q_{66} \end{bmatrix} \begin{Bmatrix} \varepsilon_1(45^\circ) - \alpha_1 \Delta T \\ \varepsilon_2(45^\circ) - \alpha_2 \Delta T \\ \gamma_{12}(45^\circ) \end{Bmatrix}$$

$$\begin{Bmatrix} \sigma_1(45^\circ) \\ \sigma_2(45^\circ) \\ \tau_{12}(45^\circ) \end{Bmatrix} = \begin{bmatrix} 47.0 & 4.56 & 0 \\ 4.56 & 16.51 & 0 \\ 0 & 0 & 5.62 \end{bmatrix}$$

$$\times 10^9 \begin{Bmatrix} -1{,}171 \times 10^{-6} - 0.878z - 6.51 \times 10^{-6}(-100) \\ -1{,}171 \times 10^{-6} - 1.238z - 24.4 \times 10^{-6}(-100) \\ 6.12z \end{Bmatrix}$$

$$\begin{Bmatrix} \sigma_1(45^\circ) \\ \sigma_2(45^\circ) \\ \tau_{12}(45^\circ) \end{Bmatrix} = \begin{Bmatrix} -18.62 - 46{,}900z \\ 18.62 - 24{,}400z \\ 34{,}400z \end{Bmatrix} \text{MPa}$$

For $-0.000375 \text{ m} \le z \le -0.000250$ m and $0.000250 \text{ m} \le z \le 0.000375$ m,

$$\begin{Bmatrix} \sigma_1(-45^\circ) \\ \sigma_2(-45^\circ) \\ \tau_{12}(-45^\circ) \end{Bmatrix} = \begin{Bmatrix} -18.62 - 62{,}100z \\ 18.62 - 20{,}100z \\ -34{,}400z \end{Bmatrix} \text{MPa}$$

For $-0.000250 \text{ m} \le z \le -0.000125$ m and $0.000125 \text{ m} \le z \le 0.000250$ m,

$$\begin{Bmatrix} \sigma_1(0^\circ) \\ \sigma_2(0^\circ) \\ \tau_{12}(0^\circ) \end{Bmatrix} = \begin{Bmatrix} -18.62 - 184{,}300z \\ 18.62 + 14{,}310z \\ 2{,}020z \end{Bmatrix} \text{MPa}$$

For $-0.000125\text{ m} \le z \le 0.000125\text{ m}$,

$$\begin{Bmatrix}\sigma_1(90°)\\ \sigma_2(90°)\\ \tau_{12}(90°)\end{Bmatrix} = \begin{Bmatrix}-18.62 + 75{,}300z\\ 18.62 - 58{,}900z\\ -2{,}020z\end{Bmatrix}\text{ MPa}$$

The first term in the expressions for the stresses are the stresses due to thermal effects. Because of the quasi-isotropic nature of the laminate, every layer experiences identical thermally induced stresses, and the stress perpendicular to the fiber direction σ_2 is equal to but opposite in value to the stress in the fiber direction σ_1. There are no thermally induced shear stresses. The second terms, the terms linear in z, are the stresses due to the applied moment. These stresses vary linearly with z within each layer, but are discontinous from layer to layer. The through-thickness distributions of the thermally induced and moment-induced stresses are plotted separately in Figs. 5.6.15 and 5.6.16, respectively.

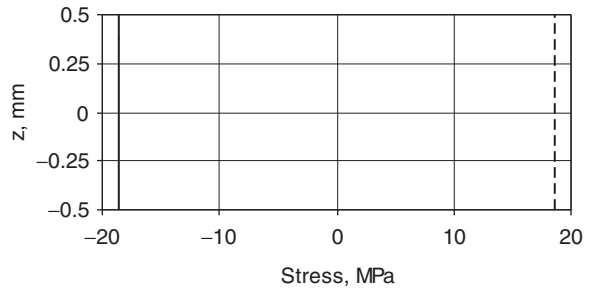

Fig. 5.6.15 Through-thickness distribution of stresses due to thermal effects: σ_1, solid; σ_2, dotted; $\tau_{12} = 0$.

It is seen that the largest tensile and compressive stresses in the principal material coordinate system due to the applied moment occur in layers 3 and 6, respectively, not in the outer layers. This is very much unlike the stress distributions in a conventional material such as aluminum or steel, where the stresses with the largest magnitude occur at $z = \pm H/2$. This characteristic of layered materials is often overlooked.

ENGINEERING PROPERTIES OF A LAMINATE

Often there is interest in what can be considered smeared engineering properties for a laminate. For example, it may be desirable to treat a laminate as a bar or beam made of a homogeneous material with an equivalent modulus. Since a bar is usually associated with tension, or compression, and a beam is usually associated with bending, the equivalent modulus for a laminated composite bar could be different than the equivalent modulus for a laminated composite beam. This makes sense, since the *A*s depend differently on the thicknesses and locations of the layers than the *D*s. Given a bar and a one-dimensional state of stress, the stress-strain behavior can be described by

$$\sigma_x = E_x\varepsilon_x \tag{5.6.62}$$

where E_x is the extensional modulus of the material. If a material is homogeneous, then the stress will be uniform through the thickness. However, it has been shown in the examples that, in general, for a laminated material the stress is not uniform through the thickness. Therefore, consider the stress in Eq. (5.6.62) to be the *average* stress $\overline{\sigma}_x$. Then, considering that under tension or compression the strain in a bar constructed of a symmetric balanced laminate would be that given by the geometric midsurface, or reference surface, strain, Eq. (5.6.62) can be rewritten as

$$\overline{\sigma}_x = E_x\varepsilon_x^o \tag{5.6.63}$$

The integral definition of the stress resultant N_x in Eq. (5.6.31) would reduce to

$$N_x = \overline{\sigma}_x H \tag{5.6.64}$$

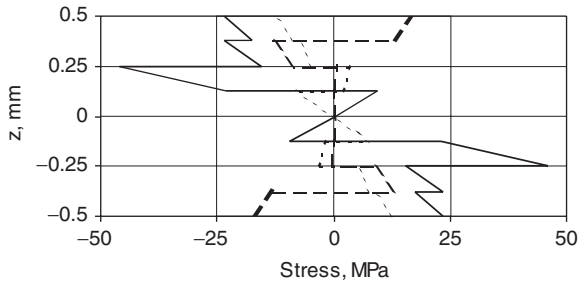

Fig. 5.6.16 Through-thickness distribution of stresses due to applied moment: σ_1, solid; σ_2, dotted; τ_{12}, dashed.

where, recall, H is the thickness of the laminate. For a bar N_y and N_{xy} would be zero, resulting in, from Eq. (5.6.53),

$$\varepsilon_x^o = a_{11}N_x \tag{5.6.65}$$

Combining Eqs. (5.6.63) to (5.6.65) leads to

$$\varepsilon_x^o = \frac{\overline{\sigma}_x}{E_x} = a_{11}N_x = a_{11}\overline{\sigma}_x H \tag{5.6.66}$$

By equating the second and fourth parts of the relationship, the equivalent extensional modulus can thus be defined as

$$(E_x)_{\text{extension}} = \frac{1}{a_{11}H} \tag{5.6.67}$$

In a similar fashion, if, instead of tension, bending is considered, then for a homogeneous material the well-known moment-curvature relation for bending of a beam in the x direction can be written as

$$M_x b = -E_x I\frac{d^2w^o}{dx^2} = E_x I\kappa_x^o \tag{5.6.68}$$

where I is the second moment of area of the rectangular cross section beam and is given by

$$I = \frac{1}{12}bH^3 \tag{5.6.69}$$

The quantity b is the width of the beam (dimension in the y direction in Fig. 5.6.11) that must be included with the moment since the definition of moment M_x as used herein is moment per unit in-plane dimension in the y direction. For bending of a beam, M_y and M_{xy} would be zero, so the curvature in the x direction for a symmetric balanced laminate is given by, from Eq. (5.6.55),

$$\kappa_x^o = d_{11}M_x \tag{5.6.70}$$

Combining Eqs. (5.6.68) to (5.6.70) results in

$$\kappa_x^o = \frac{M_x b}{E_x I} = \frac{M_x b}{E_x\left(\frac{1}{12}bH^3\right)} = d_{11}M_x \tag{5.6.71}$$

Using the third and fourth parts of the relationship provides the definition of the bending modulus as

$$(E_x)_{\text{bending}} = \frac{12}{d_{11}H^3} \tag{5.6.72}$$

EXAMPLE 21. Compute the extensional and bending modulus in the x direction for an eight-layer $[\pm 45/0/90]_s$ laminate.

APPROACH. Use the results of Example 12 directly in Eqs. (5.6.67) and (5.6.72).

SOLUTION

$$(E_x)_{\text{extension}} = \frac{1}{a_{11}H} = \frac{1}{39.8 \times 10^{-9}(8 \times 0.000125)} = 25.1\text{ GPa}$$

$$(E_x)_{\text{bending}} = \frac{12}{d_{11}H^3} = \frac{12}{0.588(8 \times 0.000125)^3} = 20.4\text{ GPa}$$

Note the bending modulus is lower than the extensional modulus because the 0° layers are near the center of the laminate and have less influence on resistance to bending than on resistance to extension.

FAILURE OF COMPOSITE MATERIALS

Generally, the calculation of the stresses within a laminate is carried out so that the values of the stresses can be compared with values known to cause failure. Knowing the levels of the stresses without having a metric to compare the stresses to is generally not useful. Most often it is of interest to know what value of applied load for a particular laminate in a particular loading situation causes failure. As might be expected, failure of fiber-reinforced composite materials is a complex process, and historically no aspect of the behavior of composite materials has been studied and debated more than the issue of failure. The topic is complex because of the multiple modes of failure and because the strength of a composite material in tension is considerably different than the strength in compression. A composite can fail due to excess stress in the fiber direction, and the strength in the fiber direction in tension is greater than the strength in compression. Alternatively, a composite material can fail because of excess stress perpendicular to the fibers. The strength perpendicular to the fibers in tension is considerably less than the strength in compression. And finally, a composite can fail due to excess shear stress. The strength in shear is considerable less than the strength in tension in the fiber direction, although the strength in shear does not depend on the sign of the shear stress. These issues are further complicated by the fact that when the fibers are oriented at an angle relative to the loading direction, through the transformation relations, there is a stress component in the fiber direction, a component perpendicular to the fiber direction, and a shear stress. Which component of stress leads to failure? Or is it a combination of the components? If it is a combination, how should the stresses be combined to predict failure?

There are many issues related to failure of composite materials and there are a number of failure theories. Some theories are quite straightforward, while others are complicated and require a considerable number of experiments to determine all the parameters necessary to implement the theory. No one theory, or criterion, works perfectly for all materials in all situations. It is better to think of failure theories as *indicators* of failure rather than *predictors* of failure. Also, failure in one layer due to excess stress perpendicular to the fibers, for example, does not necessarily mean catastrophic failure of the entire laminate. The other layers may be able to assume a greater portion of the load to compensate for the failed layer. Thus the issue of failure really becomes one of damage accumulation. With this viewpoint, failure of a laminate will occur when there is sufficient damage accumulation that not enough undamaged material remains to support the applied load. The level of **damage accumulation** that can be accepted depends on the application. For example, excess tensile stress perpendicular to the fibers generally causes cracking of a composite material, the cracks being parallel with the fibers. If some cracking is acceptable, then the prediction of cracking does not equate to failure of the laminate. However, the existence of any cracking at all is equivalent to the accumulation of some degree of damage. How much cracking can be tolerated depends very much on the application.

One failure theory that is easy to implement is the **maximum stress failure criterion.** The maximum stress failure criterion independently treats tension failure in the fiber direction, compression failure in the fiber direction, tension failure perpendicular to the fiber direction, compression failure perpendicular to the fiber direction, and failure in shear. There are thus five possible modes of failure for a plane stress state. A known level of failure stress for each mode is required. Failure in tension in the fiber direction is a direct result of fibers fracturing or otherwise breaking. Failure in compression in the fiber direction is due to the kinking of fibers, generally due to the lack of support of the matrix material surrounding the fibers and the development of shear, or kink, bands within the fiber. Failure in tension perpendicular to the fibers is due to failure of the matrix material between the fibers, failure of the fibers, failure of the bond between the matrix material and the fibers, or a combination of all three failures. Failure in compression perpendicular to the fibers is generally due to crushing of the matrix material. Finally, failure in shear is also due to failure of the matrix material between the fibers, failure of the fibers, failure of the bond between the matrix material and the fibers, or a combination of all three. It is important to realize there is a variability to failure strengths, so the approach to take is to employ allowable stress levels for each mode that adequately account for the variability. If these definitions for failure stresses in each of the modes are used

σ_1^T = tensile failure stress in the 1 direction
σ_1^C = compression failure stress in the 1 direction (a negative number)
σ_2^T = tensile failure stress in the 2 direction
σ_2^C = compression failure stress in the 2 direction (a negative number)
τ_{12}^F = shear failure stress in 1-2 plane (a positive number)

then the maximum stress failure criterion states that failure occurs at a point in a laminate if any of the following six equalities are satisfied:

$$\begin{aligned} \sigma_1 &= \sigma_1^T \qquad \sigma_1 = \sigma_1^C \\ \sigma_2 &= \sigma_2^T \qquad \sigma_2 = \sigma_2^C \\ \tau_{12} &= \tau_{12}^F \qquad \tau_{12} = -\tau_{12}^F \end{aligned} \tag{5.6.73}$$

The last two equations can be replaced by one, namely,

$$|\tau_{12}| = \tau_{12}^F \tag{5.6.74}$$

EXAMPLE 22. A thin-walled cylindrical pressure vessel with radius $R = 0.25$ m is constructed using eight layers of glass-fiber-reinforced material and a stacking sequence of $[\pm 60/0/90]_S$. The fiber angles are specified relative to the axial direction of the cylinder. The end caps of the vessel are suitably designed and reinforced, so the concern is with failure away from the end caps. The change in temperature due to curing is −100°C. The level of internal pressure is increased from zero. In what layer, or layers, does the first failure occur, what is the mode of failure, and what is the pressure level?

APPROACH. Since interest centers on the stresses away from the end caps, the stress resultants acting within the cylinder wall due to the internal pressure can be determined by considering the equilibrium of a section of cylinder away from the end caps, just as is done with conventional materials. These stress resultants will be a function of the cylinder radius as well as the pressure. By using the stress resultants, a stress analysis of the laminate can be conducted.

SOLUTION. As shown in Fig. 5.6.17, by considering equilibrium in the Y direction of the section of cylinder of length ΔL, and equilibrium in the X direction of the flat end cap, the axial and circumferential stress resultants acting on the cylinder wall can be computed as a function of pressure and cylinder radius.

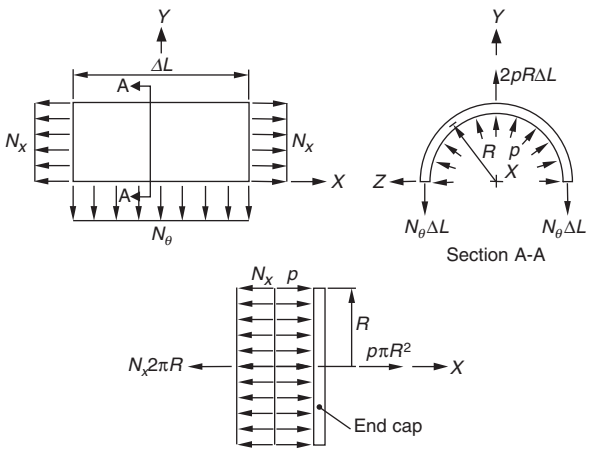

Fig. 5.6.17 Forces acting on section of cylinder away from end caps and on end caps.

Summing forces in the X direction on the end cap and in the Y direction of the section cylinder results in

$$\sum F_X = 0 : p\pi R^2 - N_x 2\pi R = 0 \rightarrow N_x = \tfrac{1}{2} pR$$
$$\sum F_Y = 0 : 2pR\,\Delta L - 2N_\theta\,\Delta L = 0 \rightarrow N_\theta = pR$$

or
$$\begin{Bmatrix} N_x \\ N_\theta \\ N_{x\theta} \end{Bmatrix} = \begin{Bmatrix} \frac{1}{2} \\ 1 \\ 0 \end{Bmatrix} pR$$

where, for generality, the results are left in term of p and R. These are the only two non-zero stress resultants acting within the cylinder wall away from the end caps due to the internal pressure. There are no moment resultants. There are, of course, equivalent thermal force resultants from Example 9 given by

$$\begin{Bmatrix} \hat{N}_x^T \\ \hat{N}_\theta^T \\ 0 \end{Bmatrix} = \begin{Bmatrix} 427 \\ 423 \\ 0 \end{Bmatrix} \frac{\text{N/m}}{^\circ\text{C}}$$

As can be seen, the subscript y in the nomenclature has been replaced by the subscript θ for this particular problem. This problem is like Example 19 as there are no moment resultants, and therefore no reference surface curvatures, only reference surface strains. However, the problem is unlike Example 19 in that the applied load level, in this case the internal pressure level, is not known. This is not a problem. The unknown pressure can be carried along symbolically in the calculations. Accordingly, from Eqs. (5.6.53) and (5.6.54), with numerical values from Examples 9 and 16, the reference surface strains are given by

$$\begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_\theta^o \\ \gamma_{x\theta}^o \end{Bmatrix} = [a] \begin{Bmatrix} N_x + \hat{N}_x^T \Delta T \\ N_y + \hat{N}_y^T \Delta T \\ N_{xy} + \hat{N}_{xy}^T \Delta T \end{Bmatrix}$$
$$= \begin{bmatrix} 43.1 & -10.00 & 0 \\ -10.00 & 33.0 & 0 \\ 0 & 0 & 116.2 \end{bmatrix} \times 10^{-9} \begin{Bmatrix} \frac{1}{2} pR + 427(-100) \\ pR + 423(-100) \\ 0\,pR \end{Bmatrix}$$

For convenience, the pressure p in pascals is converted to atmospheres by using the relation

$$p = 101{,}400\, p_a$$

where p_a is the internal pressure in atmospheres. The reference surface strains become

$$\begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_\theta^o \\ \gamma_{x\theta}^o \end{Bmatrix} = \begin{Bmatrix} -1{,}418 + 1{,}172\, p_a R \\ -970 + 2{,}840\, p_a R \\ 0\, p_a R \end{Bmatrix} \times 10^{-6}$$

The strains in the principal material coordinate system for the layers with 60° fiber orientation are computed from the transformation relation of Eq. (5.6.24) as

$$\begin{Bmatrix} \varepsilon_1(60^\circ) \\ \varepsilon_2(60^\circ) \\ \frac{1}{2}\gamma_{12}(60^\circ) \end{Bmatrix} = [T(60^\circ)] \begin{Bmatrix} \varepsilon_x^o \\ \varepsilon_\theta^o \\ \gamma_{x\theta}^o \end{Bmatrix}$$
$$= \begin{bmatrix} \frac{1}{4} & \frac{3}{4} & \frac{\sqrt{3}}{2} \\ \frac{3}{4} & \frac{1}{4} & -\frac{\sqrt{3}}{2} \\ -\frac{\sqrt{3}}{4} & \frac{\sqrt{3}}{4} & -\frac{1}{2} \end{bmatrix} \begin{Bmatrix} -1{,}418 + 1{,}172\, p_a R \\ -970 + 2{,}840\, p_a R \\ 0\, p_a R \end{Bmatrix} \times 10^{-6}$$

Carrying out the algebra and doing the same for the other layer orientations give

$$\begin{Bmatrix} \varepsilon_1(60^\circ) \\ \varepsilon_2(60^\circ) \\ \gamma_{12}(60^\circ) \end{Bmatrix} = \begin{Bmatrix} -1{,}082 + 2{,}420\, p_a R \\ -1{,}306 + 1{,}589\, p_a R \\ 388 + 1{,}446\, p_a R \end{Bmatrix} \times 10^{-6}$$
$$\begin{Bmatrix} \varepsilon_1(-60^\circ) \\ \varepsilon_2(-60^\circ) \\ \gamma_{12}(-60^\circ) \end{Bmatrix} = \begin{Bmatrix} -1{,}082 + 2{,}420\, p_a R \\ -1{,}306 + 1{,}589\, p_a R \\ -388 - 1{,}446\, p_a R \end{Bmatrix} \times 10^{-6}$$
$$\begin{Bmatrix} \varepsilon_1(0^\circ) \\ \varepsilon_2(0^\circ) \\ \gamma_{12}(0^\circ) \end{Bmatrix} = \begin{Bmatrix} -1{,}418 + 1{,}172\, p_a R \\ -970 + 2{,}840\, p_a R \\ 0 \end{Bmatrix} \times 10^{-6}$$
$$\begin{Bmatrix} \varepsilon_1(90^\circ) \\ \varepsilon_2(90^\circ) \\ \gamma_{12}(90^\circ) \end{Bmatrix} = \begin{Bmatrix} -970 + 2{,}840\, p_a R \\ -1{,}418 + 1{,}172\, p_a R \\ 0\, p_a R \end{Bmatrix} \times 10^{-6}$$

The stresses in the various layers can be computed using Eq. (5.6.20) and the above strains as follows:

$$\begin{Bmatrix} \sigma_1(60^\circ) \\ \sigma_2(60^\circ) \\ \tau_{12}(60^\circ) \end{Bmatrix} = [Q] \begin{Bmatrix} \varepsilon_1(60^\circ) - \alpha_1 \Delta T \\ \varepsilon_2(60^\circ) - \alpha_2 \Delta T \\ \gamma_{12}(60^\circ) \end{Bmatrix}$$
$$= \begin{bmatrix} 47.0 & 4.56 & 0 \\ 4.56 & 16.51 & 0 \\ 0 & 0 & 5.62 \end{bmatrix}$$
$$\times 10^9 \begin{Bmatrix} -1{,}082 + 2{,}420 p_a R - 6.51(-100) \\ -1{,}306 + 1{,}589 p_a R - 24.4(-100) \\ 388 + 1{,}446\, p_a R \end{Bmatrix} \times 10^{-6}$$

Carrying out the algebra, substituting for the radius with $R = 0.25$ m, and doing similar calculations for the other three layer angles result in

$$\begin{Bmatrix} \sigma_1(60^\circ) \\ \sigma_2(60^\circ) \\ \tau_{12}(60^\circ) \end{Bmatrix} = \begin{Bmatrix} -15.08 + 30.3\, p_a \\ 16.78 + 9.32\, p_a \\ 2.18 + 2.03\, p_a \end{Bmatrix} \text{MPa}$$
$$\begin{Bmatrix} \sigma_1(-60^\circ) \\ \sigma_2(-60^\circ) \\ \tau_{12}(-60^\circ) \end{Bmatrix} = \begin{Bmatrix} -15.08 + 30.3\, p_a \\ 16.78 + 9.32\, p_a \\ -2.18 - 2.03\, p_a \end{Bmatrix} \text{MPa}$$
$$\begin{Bmatrix} \sigma_1(0^\circ) \\ \sigma_2(0^\circ) \\ \tau_{12}(0^\circ) \end{Bmatrix} = \begin{Bmatrix} -29.3 + 17.00 p_a \\ 20.8 + 13.07 p_a \\ 0\, p_a \end{Bmatrix} \text{MPa}$$
$$\begin{Bmatrix} \sigma_1(90^\circ) \\ \sigma_2(90^\circ) \\ \tau_{12}(90^\circ) \end{Bmatrix} = \begin{Bmatrix} -10.34 + 34.7 p_a \\ 15.45 + 8.08\, p_a \\ 0\, p_a \end{Bmatrix} \text{MPa}$$

By using Eq. (5.6.73), the stresses in each layer are equated to the failure levels for each failure mode, and the value of p_a is computed for each mode. Interest is in positive values of p_a, corresponding to the internal pressure as the problem is formulated here. However, for the sake of completeness, all six failure equations will be considered for the four fiber angles, resulting in 24 values of p_a. The smallest positive value is the value of internal pressure that first causes failure as the pressure is increased from zero. The corresponding layer and the corresponding mode of failure can be determined from the particular equation that leads to this lowest positive value of p_a. For convenience, the six equations of Eq. (5.6.73) are expressed as

$$\begin{Bmatrix} \sigma_1 \\ \sigma_2 \\ \tau_{12} \end{Bmatrix} = \begin{Bmatrix} \sigma_1^T \\ \sigma_2^T \\ \tau_{12}^F \end{Bmatrix} = \begin{Bmatrix} 1{,}000 \\ 30 \\ 70 \end{Bmatrix} \text{MPa} \qquad \begin{Bmatrix} \sigma_1 \\ \sigma_2 \\ \tau_{12} \end{Bmatrix} = \begin{Bmatrix} \sigma_1^C \\ \sigma_2^C \\ -\tau_{12}^F \end{Bmatrix} = \begin{Bmatrix} -600 \\ -120 \\ -70 \end{Bmatrix} \text{MPa}$$

where typical failure stress levels have been used. For the 60°layers, using megapascals, the above six failure equations are

$$\begin{Bmatrix} -15.08 + 30.3\, p_a \\ 16.78 + 9.32\, p_a \\ 2.18 + 2.03\, p_a \end{Bmatrix} = \begin{Bmatrix} 1{,}000 \\ 30 \\ 70 \end{Bmatrix} \qquad \begin{Bmatrix} -15.08 + 30.3\, p_a \\ 16.78 + 9.32\, p_a \\ 2.18 + 2.03\, p_a \end{Bmatrix} = \begin{Bmatrix} -600 \\ -120 \\ -70 \end{Bmatrix}$$

For the −60° layers, the six failure equations are

$$\begin{Bmatrix} -15.08 + 30.3\, p_a \\ 16.78 + 9.32\, p_a \\ -2.18 - 2.03\, p_a \end{Bmatrix} = \begin{Bmatrix} 1{,}000 \\ 30 \\ 70 \end{Bmatrix} \qquad \begin{Bmatrix} -15.08 + 30.3\, p_a \\ 16.78 + 9.32\, p_a \\ 2.18 - 2.03\, p_a \end{Bmatrix} = \begin{Bmatrix} -600 \\ -120 \\ -70 \end{Bmatrix}$$

For the 0° layers, the six failure equations are

$$\begin{Bmatrix} -29.3 + 17.00\, p_a \\ 20.8 + 13.07\, p_a \\ 0\, p_a \end{Bmatrix} = \begin{Bmatrix} 1{,}000 \\ 30 \\ 70 \end{Bmatrix} \qquad \begin{Bmatrix} -29.3 + 17.00\, p_a \\ 20.8 + 13.07\, p_a \\ 0\, p_a \end{Bmatrix} = \begin{Bmatrix} -600 \\ -120 \\ -70 \end{Bmatrix}$$

For the 90° layers, the six failure equations are

$$\begin{Bmatrix} -10.34 + 34.7p_a \\ 15.45 + 8.08p_1 \\ 0\,p_a \end{Bmatrix} = \begin{Bmatrix} 1{,}000 \\ 30 \\ 70 \end{Bmatrix} \qquad \begin{Bmatrix} -10.34 + 34.7p_a \\ 15.45 + 8.08p_a \\ 0\,p_a \end{Bmatrix} = \begin{Bmatrix} -600 \\ -120 \\ -70 \end{Bmatrix}$$

From these 24 equations there are 10 positive values of p_a, 10 negative values of p_a, and 4 values of infinity. The infinite values come from the two shear equations for the 0° layers and the two shear equations for the 90°layers. From these multiple values of p_a, the lowest level of the internal pressure is $p_a = 0.704$ atm. This value is obtained from the solution of the second equation for the positive failure stress levels for the 0° layer, i.e.,

$$20.8 + 13.07p_a = 30$$

This is interpreted to mean that at $p_a = 0.704$ atm cracks parallel to the fibers occur in the 0° layers due to high tensile level of stress component σ_2. If matrix cracking is to be avoided, only pressures below this level are allowed. The answer to the original question is that failures occur when $p_a = 0.704$ atm, the mode of failure is excess tensile stress perpendicular to the fibers, and it occurs in the 0° layers. To go one step beyond what was asked for, however, a negative pressure of magnitude 10.78 atm is obtained from the solution of the second equation for negative failure stress levels for the 0° layers, i.e.,

$$20.8 + 13.07p_a = -120$$

This value is the negative value of p_a with the lowest magnitude. It is interpreted to mean that an *external* pressure of 10.78 atm will cause failure of the 0° layers due to a high compressive level of stress component σ_2, assuming that the cylinder has not buckled due to the external pressure.

CHEMISTRY

Every **elementary substance** is made up of exceedingly small particles called **atoms** which are all alike and which cannot be further subdivided or broken up by **chemical processes.** It will be noted that this statement is virtually a definition of the term elementary substance and a limitation of the term chemical process. There are as many different classes or families of atoms as there are **chemical elements.** See Table 6.1.1.

Two or more atoms, either of the same kind or of different kinds, are, in the case of most elements, capable of uniting with one another to form a higher order of distinct particles called **molecules.** If the molecules or atoms of which any given material is composed are all exactly alike, the material is a **pure substance.** If they are not all alike, the material is a **mixture.**

If the atoms which compose the molecules of any pure substances are all of the same kind, the substance is, as already stated, an **elementary substance.** If the atoms which compose the molecules of a pure chemical substance are not all of the same kind, the substance is a **compound substance.** The atoms are to be considered as the smallest particles which occur separately in the structure of molecules of either compound or elementary substances, so far as can be determined by ordinary chemical analysis. The molecule of an element consists of a definite (usually small) number of its atoms. The molecule of a compound consists of one or more atoms of each of its several elements, the numbers of the

[a] All the elements for which atomic weights listed are metals, except as otherwise indicated. No atomic weights are listed for most radioactive elements, as these elements have no fixed value.

[b] The atomic weights are based upon nuclidic mass of $C^{12} = 12$.

[c] Inert gas. [d] Metalloid. [e] Liquid. [f] Gas. [g] Most active gas. [h] Lightest gas. [i] Lightest metal. [j] Not placed. [k] Liquid at 25 °C.

[l] The atomic weight varies because of natural variations in the isotopic composition of the element. The observed ranges are boron, ± 0.003; carbon, ± 0.00005; hydrogen, ± 0.00001; oxygen, ± 0.0001; silicon, ± 0.001; sulfur, ± 0.003.

[m] The atomic weight is believed to have an experimental uncertainty of the following magnitude: bromine, ± 0.001; chlorine, ± 0.001; chromium, ± 0.001; copper, ± 0.001; iron, ± 0.003; silver, ± 0.001. For other elements, the last digit given is believed to be reliable to ± 0.5.

various kinds of atoms and their arrangement being definite and fixed and determining the character of the compound. This notion of molecules and their constituent atoms is useful for interpreting the observed fact that chemical reactions—e.g., the analysis of a compound into its elements, the synthesis of a compound from the elements, or the changing of one or more compounds into one or more different compounds—take place so that the masses of the various substances concerned in a given reaction stand in definite and fixed ratios.

It appears from recent researches that some substances which cannot by any available means be decomposed into simpler substances and which must, therefore, be defined as elements, are continually undergoing spontaneous changes or **radioactive transformation** into other substances which can be recognized as physically and chemically different from the original substance. Radium is an element by the definition given and may be considered as made up of atoms. But it is assumed that these atoms, so called because they resist all efforts to break them up and are, therefore, apparently indivisible, nevertheless split up spontaneously, at a rate which scientists have not been able to influence in any way, into other atoms, thus forming other elementary substances of totally different properties. See Table 6.1.3.

The view generally accepted at present is that the atoms of all the chemical elements, including those not yet known to be radioactive, consist of several kinds of still smaller particles, three of which are known as **protons, neutrons,** and **electrons.** The protons are bound together in the atomic nucleus with other particles, including neutrons, and are positively charged. The neutrons are particles having approximately the mass of a proton but are uncharged. The electrons are negatively charged particles, all alike, external to the nucleus, and sufficient in number to neutralize the nuclear charge in an atom. The differences between the atoms of different chemical elements are due to the different numbers of these smaller particles composing them. According to the original Bohr theory, an ordinary atom is conceived as a stable system of such electrons revolving in closed orbits about the nucleus like the planets of the solar system around the sun. In a hydrogen atom, there is 1 proton and 1 electron; in a radium atom, there are 88 electrons surrounding a nucleus 226 times as massive as the hydrogen nucleus. Only a few, in general the outermost or valence electrons of such an atom, are subject to rearrangement within, or ejection from, the atom, thereby enabling it, because of its increased energy, to combine with other atoms to form molecules of either elementary substances or compounds. The **atomic number** of an

element is the number of excess positive charges on the nucleus of the atom. The essential feature that distinguishes one element from another is this charge of the nucleus. It also determines the position of the element in the periodic table. Modern researches have shown the existence of **isotopes,** that is, two or more species of atoms having the same atomic number and thus occupying the same place in the periodic system, but differing somewhat in atomic weight. These isotopes are chemically identical and are merely different species of the same chemical element. Most of the ordinary inactive elements have been shown to consist of a mixture of isotopes. This convenient atomic model should be regarded as only a working hypothesis for coordinating a number of phenomena about which much yet remains to be known.

Calculation of the Percentage Composition of Substances Add the atomic weights of the elements in the compound to obtain its molecular weight. Multiply the atomic weight of the element to be calculated by the number of atoms present (indicated in the formula by a subscript number) and by 100, and divide by the molecular weight of the compound. For example, hematite iron ore (Fe_2O_3) contains 69.94 percent of iron by weight, determined as follows: Molecular weight of Fe_2O_3 = $(55.84 \times 2) + (16 \times 3) = 159.68$. Percentage of iron in compound = $(55.84 \times 2) \times 100/159.68 = 69.94$.

SPECIFIC GRAVITIES AND DENSITIES AND OTHER PHYSICAL DATA

Table 6.1.5 Approximate Specific Gravities and Densities
(Water at 39°F and normal atmospheric pressure taken as unity) For more detailed data on any material, see the section dealing with the properties of that material. Data given are for usual room temperatures.

Substance	Specific gravity	Avg density lb/ft³	Avg density kg/m³

Compressibility of Liquids

If v_1 and v_2 are the volumes of the liquids at pressures of p_1 and p_2 atm, respectively, at any temperature, the coefficient of compressibility b is given by the equation

$$b = \frac{1}{v_1}\frac{v_1 - v_2}{p_2 - p_1}$$

The value of $b \times 10^6$ for oils at low pressures at about 70°F varies from about 55 to 80; for mercury at 32°F, it is 3.9; for chloroform at 32°F, it is 100 and increases with the temperature to 200 at 140°F; for ethyl alcohol, it increases from about 100 at 32°F and low pressures to 125 at 104°F; for glycerin, it is about 24 at room temperature and low pressure.

Table 6.1.6 Average Composition of Dry Air between Sea Level and 90-km (295,000-ft) Altitude

Element	Formula	% by Vol.	% by Mass	Molecular weight
Nitrogen	N_2	78.084	75.55	28.0134
Oxygen	0_2	20.948	23.15	31.9988

6.2 IRON AND STEEL

by Harold W. Paxton

REFERENCES: "Metals Handbook," ASM International, latest ed., ASTM Standards, pt. 1. SAE Handbook. "Steel Products Manual," AISI. "Making, Shaping and Treating of Steel," AISE, latest ed.

CLASSIFICATION OF IRON AND STEEL

Iron (Fe) is not a high-purity metal commercially but contains other chemical elements which have a large effect on its physical and mechanical properties. The amount and distribution of these elements are dependent upon the method of manufacture. The most important commercial forms of iron are listed below.

Pig iron is the product of the blast furnace and is made by the reduction of iron ore.

Cast iron is an alloy of iron containing enough carbon to have a low melting temperature and which can be cast to close to final shape. It is not generally capable of being deformed before entering service.

Gray cast iron is an iron which, as cast, has combined carbon (in the form of cementite, Fe_3C) not in excess of a eutectoid percentage—the balance of the carbon occurring as graphite flakes. The term "gray iron" is derived from the characteristic gray fracture of this metal.

White cast iron contains carbon in the combined form. The presence of cementite or iron carbide (Fe_3C) makes this metal hard and brittle, and the absence of graphite gives the fracture a white color.

Malleable cast iron is an alloy in which all the combined carbon in a special white cast iron has been changed to free or temper carbon by suitable heat treatment.

Nodular (ductile) cast iron is produced by adding alloys of magnesium or cerium to molten iron. These additions cause the graphite to form into small nodules, resulting in a higher-strength, ductile iron.

Ingot iron, electrolytic iron (an iron-hydrogen alloy), and **wrought iron** are terms for low-carbon materials which are no longer serious items of commerce but do have considerable historical interest.

Steel is an alloy predominantly of iron and carbon, usually containing measurable amounts of manganese, and often readily formable.

Carbon steel is steel that owes its distinctive properties chiefly to the carbon it contains.

Alloy steel is steel that owes its distinctive properties chiefly to some element or elements other than carbon, or jointly to such other elements and carbon. Some alloy steels necessarily contain an important percentage of carbon, even as much as 1.25 percent. There is no complete agreement about where to draw the line between the alloy steels and the carbon steels.

Basic oxygen steel and **electric-furnace steel** are steels made by the basic oxygen furnace and electric furnace processes, irrespective of carbon content; the effective individual alloy content in engineering steels can range from 0.05 percent up to 3 percent, with a total usually less than 5 percent. Open-hearth and Bessemer steelmaking are no longer practiced in the United States.

Iron ore is reduced in a blast furnace to form **pig iron,** which is the raw material for practically all iron and steel products. Formerly, nearly 90 percent of the iron ore used in the United States came from the Lake Superior district; the ore had the advantages of high quality and the cheapness with which it could be mined and transported by way of the Great Lakes. With the rise of global steelmaking and the availability of high-grade ores and pellets (made on a large scale from low-grade ores) from many sources, the choice of feedstock becomes an economic decision.

The modern **blast furnace** consists of a vertical shaft up to 10 m or 40 ft in diameter and over 30 m (100 ft) high containing a descending column of iron ore, coke, and limestone and a large volume of ascending hot gas. The gas is produced by the burning of coke in the hearth of the furnace and contains about 34 percent carbon monoxide. This gas reduces the iron ore to metallic iron, which melts and picks up considerable quantities of carbon, manganese, phosphorus, sulfur, and silicon. The **gangue** (mostly silica) of the iron ore and the ash in the coke combine with the limestone to form the blast-furnace slag. The pig iron and slag are drawn off at intervals from the hearth through the iron notch and cinder notch, respectively. Some of the larger blast furnaces produce around 10,000 tons of pig iron per day. The blast furnace produces a liquid product for one of three applications: (1) the huge majority passes to the steelmaking process for refining; (2) pig iron is used in foundries for making castings; and (3) ferroalloys, which contain a considerable percentage of another metallic element, are used as addition agents in steelmaking. Compositions of commercial pig irons and two ferroalloys (ferromanganese and ferrosilicon) are listed in Table 6.2.1.

Physical Constants of Unalloyed Iron Some physical properties of iron and even its dilute alloys are sensitive to small changes in composition, grain size, or degree of cold work. The following are reasonably accurate for "pure" iron at or near room temperature; those with an asterisk are sensitive to these variables perhaps by 10 percent or more. Those with a dagger (†) depend measurably on temperature; more extended tables should be consulted.

Specific gravity, 7.866; melting point, 1,536°C (2,797°F); heat of fusion 277 kJ/kg (119 Btu/lbm); thermal conductivity 80.2 W/(m · C) [557 Btu/(h · ft^2 · in · °F)*†; thermal coefficient of expansion 12 × 10^{-6}/°C (6.7 × 10^{-6}/°F)†; electrical resistivity 9.7 $\mu\Omega$ · cm*†; and temperature coefficient of electrical resistance 0.0065/°C (0.0036/°F).†

Mechanical Properties Representative mechanical properties of annealed low-carbon steel (often similar to the former ingot iron) are as follows: yield strength 130 to 150 MPa (20 to 25 ksi); tensile strength 260 to 300 MPa (40 to 50 ksi); elongation 20 to 45 percent in 2 in; reduction in area of 60 to 75 percent; Brinell hardness 65 to 100. These figures are at best approximate and depend on composition (especially trace additives) and processing variables. For more precise data, suppliers or broader databases should be consulted.

Young's modulus for ingot iron is 202,000 MPa (29,300,000 lb/in^2) in both tension and compression, and the shear modulus is 81,400 MPa (11,800,000 lb/in^2). Poisson's ratio is 0.28. The **effect of cold rolling** on the tensile strength, yield strength, elongation, and shape of the stressstrain curve is shown in Fig. 6.2.1, which is for Armco ingot iron but would not be substantially different for other low-carbon steels.

Uses Low-carbon materials weld evenly and easily in all processes, can be tailored to be readily paintable and to be enameled, and with other treatments make an excellent low-cost soft magnetic material with high permeability and low coercive force for mass-produced motors and transformers. Other uses, usually after galvanizing, include culverts, flumes, roofing, siding, and housing frames; thin plates can be used in oil and water tanks, boilers, gas holders, and various nondemanding pipes; enameled sheet retains a strong market in ranges, refrigerators, and other household goods, in spite of challenges from plastics.

World Production From about 1970 to 1995, the annual world production of steel was remarkably steady at some 800,000,000 tons. Reductions in some major producers (United States, Japan, some European countries, and the collapsing U.S.S.R.) were balanced by the many smaller countries which began production. The struggle for markets led to pricing that did not cover production costs and led to international political strains. A major impact began in the 1990s as China pushed its own production from a few tens of million tons toward 300,000,000 tons in 2004, pushing world production to over 1 billion tons.

Table 6.2.1 Types of Pig Iron for Steelmaking and Foundry Use

Designation	Chemical composition, %*				Principal use
	Si	P	Mn	C†	
Basic pig, northern	1.50 max	0.400 max	1.01–2.00	3.5–4.4	Basic oxygen steel
In steps of	0.25		0.50		
Foundry, northern	3.50 max	0.301–0.700	0.50–1.25	3.0–4.5	A wide variety of castings
In steps of	0.25		0.25		
Foundry, southern	3.50 max	0.700–0.900	0.40–0.75	3.0–4.5	Cast-iron pipe
In steps of	0.25		0.25		
Ferromanganese (3 grades)	1.2 max	0.35 max	74–82	7.4 max	Addition of manganese to steel or cast iron
Ferrosilicon (silvery pig)	5.00–17.00	0.300 max	1.00–2.00	1.5 max	Addition of silicon to steel or cast iron

* Excerpted from "The Making, Shaping and Treating of Steel," AISE, 1984; further information in "Steel Products Manual," AISI, and ASTM Standards, Pt. 1.
† Carbon content not specified—for information only. Usually S is 0.05 max (0.06 for ferrosilicon) but S and P for basic oxygen steel are typically much lower today.

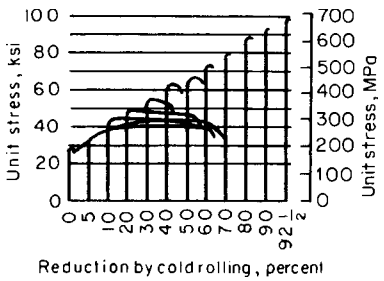

Fig. 6.2.1 Effect of cold rolling on the stress-strain relationship of Armco ingot iron. *(Kenyon and Burns.)*

The world raw material infrastructure (iron ore, coke, and scrap) was not able to react quickly to support this increase, and prices soared; steel prices followed. Recently (2006) long-term ore contracts reflected large price increases, so it appears that for some time **steel prices** will remain high by historical comparisons. The effects of material substitution are not yet clear, but as end users examine their options more closely, the marketplace will most likely settle the matter.

STEEL

Steel Manufacturing

Steel is produced by the removal of impurities from pig iron in a basic oxygen furnace or an electric furnace.

Basic Oxygen Steel This steel is produced by blowing pure (99 percent) oxygen either vertically under high pressure (1.2 MPa or 175 lb/in^2) onto the surface of molten pig iron (BOP) or through tuyeres in the base of the vessel (the Q-BOP process). Some facilities use a combination depending on local circumstances and product mix. This is an autogenous process that requires no external heat to be supplied. The furnaces are similar in shape to the former Bessemer converters but range in capacity to 275 metric tons (t) (300 net tons) or more. The barrel-shaped furnace or vessel may or may not be closed on the bottom, is open at the top, and can rotate in a vertical plane about a horizontal axis for charging and for pouring the finished steel. Selected scrap is charged into the vessel first, up to 30 percent by weight of the total charge. Molten pig iron (often purified from the raw blast-furnace hot metal to give lower sulfur, phosphorus, and sometimes silicon) is poured into the vessel. In the Q-BOP, oxygen must be flowing through the bottom tuyeres at this time to prevent clogging; further flow serves to refine the charge and carries in fluxes as powders. In the BOP process, oxygen is introduced through a water-cooled lance introduced through the top of the vessel. Within seconds after the oxygen is turned on, some iron in the charge is converted to ferrous oxide, which reacts rapidly with the impurities of the charge to remove them from the metal. As soon as reaction starts, limestone is added as a flux. Blowing is continued until the desired degree of purification is attained. The reactions take place very rapidly, and blowing of a heat is completed in about 20 min in a 200-net-ton furnace. Because of the speed of the process, a computer is used to calculate the charge required for making a given heat of steel, the rate and duration of oxygen blowing, and to regulate the quantity and timing of additions during the blow and for finishing the steel. Production rates of well over 270 t per furnace hour (300 net tons) can be attained. The comparatively low investment cost and low cost of operation have already made the basic oxygen process the largest producer of steel in the world, and along with electric furnaces, it almost completely replaces the basic open hearth as the major steelmaking process. No open hearths operate in the United States today.

Electric Steel The biggest change in steelmaking over the last 20 years is the fraction of steel made by remelting scrap in an electric furnace (EF), originally to serve a relatively nondemanding local market, but increasingly moving up in quality and products to compete with mills using the blast-furnace/oxygen steelmaking route. The economic competition is fierce and has served to improve choices for customers. In the last decade the fraction of steel made in the EF in the United States has gone above 50 percent by a combination of contraction in blast-furnace (BF) production (no new ones built, retirement of some, and a shortage of suitable coke) and an increase of total production, which has been met with EFs. At one time, there was concern that some **undesirable elements in scrap** that are not eliminated in steelmaking, notably copper and zinc, would increase with remelting cycles. However, the development of alternative **iron units** (direct reduced iron, iron carbide, and even pig iron) to dilute scrap additions has at least postponed this as an issue.

Early processes used three-phase alternating current, but increasingly the movement is to a single dc electrode with a conducting hearth. The high-power densities necessitate water cooling and improved basic refractory linings. Scrap is charged into the furnace, which usually contains some of the last heat to improve efficiency. Older practices often had a second slag made after the first meltdown and refining by oxygen blowing, but today, final refining takes place outside the melting unit in a ladle furnace, which allows refining, temperature control, and alloying additions to be made without interfering with the next heat. The materials are **continuously cast** including slabs only 50 mm (2 in) thick and casting directly to sheet in the 1- to 2-mm (0.04- to 0.08-in) thickness range is passing through the pilot stage.

The degree to which electric melting can replace more conventional methods is of great interest and depends in large part on the availability of sufficiently pure scrap at an attractive price and some improvements in surface quality to be able to make the highest-value products. Advances in EF technology are countered aggressively by new developments and cost control in traditional steelmaking; it may well be a decade or more before the pattern clarifies.

The **induction furnace** is simply a fairly small melting furnace to which the various metals are added to make the desired alloy, usually quite specialized. When steel scrap is used as a charge, it will be a high-grade scrap the composition of which is well known (see also Sec. 7).

Ladle Metallurgy One of the biggest contributors to quality in steel products is the concept of refining liquid steel outside the first melting unit—BOP, Q-BOP, or EF, none of which is well designed to perform

the final refining function. In this separate unit, gases in solution (oxygen, hydrogen, and, to a lesser extent, nitrogen) can be reduced by vacuum treatment, carbon can be adjusted to desirable very low levels by reaction with oxygen in solution, alloy elements can be added, the temperature can be adjusted, and the liquid steel can be stirred by inert gases to float out inclusions and provide a homogeneous charge to the continuous casters which are now virtually ubiquitous. Reducing oxygen in solution means a "cleaner" steel (fewer nonmetallic inclusions) and a more efficient recovery of active alloying elements added with a purpose and which otherwise might end up as oxides.

Steel Ingots With the advent of continuous casters, ingot casting is now generally reserved for the production of relatively small volumes of material such as heavy plates and forgings which are too big for current casters. Ingot casting, apart from being inefficient in that the large volume change from liquid to solid must be handled by discarding the large void space usually at the top of the ingot (the **pipe**), also has several other undesirable features caused by the solidification pattern in a large volume, most notably significant differences in composition throughout the piece (**segregation**) leading to different properties, **inclusions** formed during solidification, and surface flaws from poor mold surfaces, splashing and other practices, which if not properly removed lead to defects in finished products (**seams, scabs, scale,** etc.). Some defects can be removed or attenuated, but others cannot; in general, with the exception of some very specialized tool and bearing steels, products from ingots are no longer state-of-the-art unless they are needed for size.

Continuous Casting This concept, which began with Bessemer in the 1850s, began to be a reliable production tool around 1970 and since then has replaced basically all ingot casting. Industrialized countries all continuously cast close to 100 percent of their production. Sizes cast range from 2-m (80-in)—or more—by 0.3-m (12-in) **slabs** down to 0.1-m (4-in) square or round **billets.** Multiple strands are common where production volume is important. Many heats of steel can be cast in a continuous string with changes of width possible during operation. Changes of composition are possible in succeeding ladles with a discard of the short length of mixed composition.

By intensive process control, it is often possible to avoid cooling the cast slabs to room temperature for inspection, enabling energy savings since the slabs require less reheating before hot rolling. If for some reason the slabs are cooled to room temperature, any surface defects which might lead to quality problems can be removed—usually by **scarfing** with an oxyacetylene torch or by grinding. Since this represents a yield loss, there is a real economic incentive to avoid the formation of such defects by paying attention to casting practices.

Mechanical Treatment of Steel

Cast steel, in the form of slabs, billets, or bars (these latter two differ somewhat arbitrarily in size) is treated further by various combinations of hot and cold deformation to produce a finished product for sale from the mill. Further treatments by fabricators usually occur before delivery to the final customer. These treatments have three purposes: (1) to change the shape by deformation or metal removal to desired tolerances; (2) to break up—at least partially—the segregation and large grain sizes inevitably formed during the solidification process and to redistribute the nonmetallic inclusions which are present; and (3) to change the properties. For example, these may be functional—strength or toughness—or largely aesthetic, such as reflectivity.

These purposes may be separable or in many cases may be acting simultaneously. An example is hot-rolled sheet or plate in which often the rolling schedule (reductions and temperature of each pass, and the cooling rate after the last reduction) is a critical path to obtain the properties and sizes desired and is often known as "heat treatment on the mill." The development of controls to do this has allowed much higher tonnages at attractive prices, and increasing robustness of rolls has allowed steel to be hot-rolled down to the 1 mm (0.04-in) range, where it can compete with the more expensive "cold-rolled" material.

Most steels are reduced after appropriate heating (to above 1,000°C) in various multistand hot rolling mills to produce **sheet, strip, plate, tubes, shaped sections,** or **bars.** More specialized deformation, e.g., by **hammer forging,** can result in working in more than one direction, with a distribution of inclusions which is not extended in one direction. Rolling, e.g., more readily imparts anisotropic properties. **Press forging** at slow strain rates changes the worked structure to greater depths and is preferred for high-quality products. The degree of reduction required to eliminate the cast structure varies from 4:1 to 10:1; clearly smaller reductions would be desirable but are currently not usual.

The slabs, blooms, and billets from the caster must be reheated in an atmosphere-controlled furnace to the working temperature, often from room temperature, but if practices permit, they may be charged hot to save energy. Coupling the hot deformation process directly to slabs at the continuous caster exit is potentially more efficient, but practical difficulties currently limit this to a small fraction of total production.

The steel is oxidized during heating to some degree, and this oxidation is removed by a combination of light deformation and high-pressure water sprays before the principal deformation is applied. There are differences in detail between processes, but as a representative example, the conventional production of wide "hot-rolled sheet" [>1.5 m (60 in)] will be discussed.

The slab, about 0.3 m (12 in) thick at about 1200°C is passed through a *scale breaker* and high-pressure water sprays to remove the oxide film. It then passes through a set of *roughing passes* (possibly with some modest width reduction) to reduce the thickness to just over 25 mm (1 in), the ends are sheared perpendicular to the length to remove irregularities, and finally they are fed into a series of up to seven roll stands each of which creates a reduction of 50 to 10 percent passing along the train. Process controls allow each mill stand to run sufficiently faster than the previous one to maintain tension and avoid pileups between stands. The temperature of the sheet is a balance between heat added by deformation and that lost by heat transfer, sometimes with interstand water sprays. Ideally the temperature should not vary between head and tail of the sheet, but this is hard to accomplish.

The deformation encourages recrystallization and even some grain growth between stands; even though the time is short, temperatures are high. Emerging from the last stand between 815 and 950°C, the **austenite*** may or may not recrystallize, depending on the temperature. At higher temperatures, when austenite does recrystallize, the grain size is usually small (often in the 10- to 20-μm range). At lower exit temperatures austenite grains are rolled into "pancakes" with the short dimension often less than 10 μm. Since several **ferrite*** grains nucleate from each austenite grain during subsequent cooling, the ferrite grain size can be as low as 3 to 6 μm (ASTM 14 to 12). We shall see later that small ferrite grain sizes are a major contributor to the superior properties of today's carbon steels, which provide good strength and superior toughness simultaneously and economically.

Some of these steels also incorporate strong **carbide*** and **nitride*** formers in small amounts to provide extra strength from precipitation hardening; the degree to which these are undissolved in austenite during hot rolling affects recrystallization significantly. The subject is too complex to treat briefly here; the interested reader is referred to the ASM "Metals Handbook."

After the last pass, the strip may be cooled by programmed water sprays to between 510 and 730°C so that during coiling, any desired precipitation processes may take place in the coiler. The finished coil, usually 2 to 3 mm (0.080 to 0.120 in) thick and sometimes 1.3 to 1.5 mm (0.052 to 0.060 in) thick, which by now has a light oxide coating, is taken off line and either shippped directly or retained for further processing to make higher value-added products. Depending on composition, typical values of yield strength are from 210 up to 380 MPa (30 to 55 ksi), UTS in the range of 400 to 550 MPa (58 to 80 ksi), with an elongation in 200 mm (8 in) of about 20 percent. The higher strengths correspond to low-alloy steels.

About half the sheet produced is sold directly as **hot-rolled sheet.** The remainder is further cold-worked after scale removal by **pickling** and either is sold as cold-worked to various **tempers** or is recrystallized to form a very formable product known as **cold-rolled and annealed,**

* See Fig. 6.2.4 and the discussion thereof.

or more usually as **cold-rolled,** sheet. Strengthening by cold work is common in sheet, strip, wire, or bars. It provides an inexpensive addition to strength but at the cost of a serious loss of ductility, often a better surface finish, and a finished product held to tighter tolerances. It improves springiness by increasing the yield strength, but does not change the elastic moduli. Examples of the effect of cold working on carbon-steel drawn wires are shown in Figs. 6.2.2 and 6.2.3.

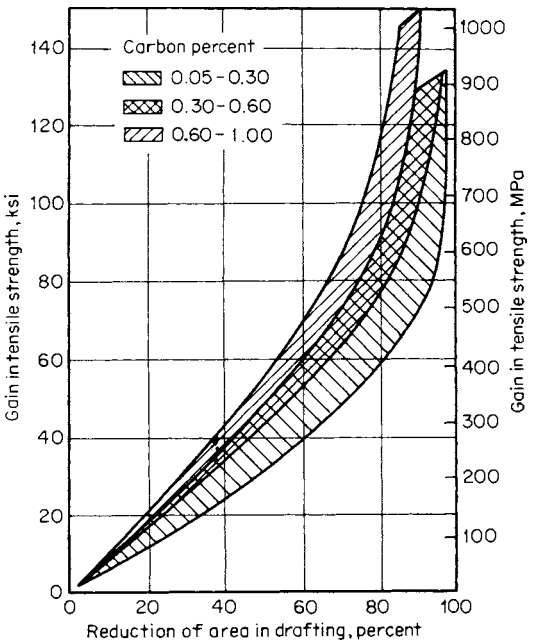

Fig. 6.2.2 Increase of tensile strength of plain carbon steel with increasing amounts of cold working by drawing through a wire-drawing die.

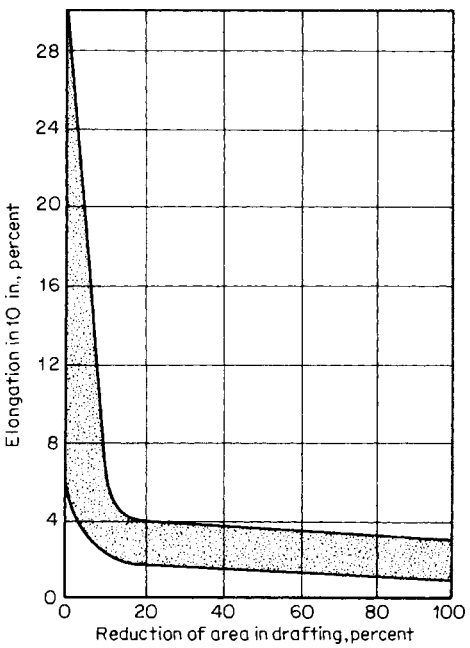

Fig. 6.2.3 Reduction in ductility of plain carbon steel with increasing amounts of cold working by drawing through a wire-drawing die.
